INDEX

A

Accident at Mountain-King mine.....	Page 705
At American metallurgical plants.....	92
In Butte mines in 1916.....	204
Adaptability of machinery.....	773
Adaptation of mining methods to geology and topography.....	298
Adelaide, Nevada, noises in mines.....	298
Adventure, the Great.....	298
Aerial tram, Spanish Peak.....	831
Tramway, Saline Valley.....	269
F. C. Carstarphen.....	913
Aeroplanes, vanadium for.....	555
African copper, Katanga.....	573
Agitation of slime.....	296
Agitator, the Propeller.....	400
Old Subscriber.....	477
Magma zinc plant.....	583
Agricultural annexes of mines.....	554
Aid to the national cause.....	187
Air for mine workings.....	103
Pressure tank safety orders in California.....	498
Ship as a carrier of metals.....	102
Alaska gold mines in 1916.....	23
Metal production in 1916.....	80
Mining, Government aid to.....	246
Roads.....	588
Semi-Centennial.....	624
Spruce for mine-timbers.....	202
Alaska Gold Mines Co., review of financial condition.....	282
Alaska Juneau v. Ebner re water-rights.....	671
Alaska Treadwell caving and flooding of.....	589
Mines, subsidence in.....	197
Alcohol laws, restrictive.....	720
Alien rights in mine location.....	451
Alkali land, neutralized by sulphuric acid.....	646
Allen, A. W.....	362
Crushing in Krupp-type ball-mills.....	823
Allies, copper needs of.....	31
Allison Ranch mine, California, progress at.....	204
Alloy, definition of.....	704
Easily fusible.....	518
Expansion of.....	336
Non-corrosive, cobalt-iron.....	886
Of aluminum and calcium.....	451
Altitude of valuable mines.....	308
Alum purifies water.....	773
Aluminum alloy, acceiral.....	272
And steel, action.....	497
As a substitute for zinc.....	886
Calcium alloy.....	86
Dust prices.....	515
Dust precipitation tests.....	196
Melting scrap.....	235
Money in France and Germany.....	90
Replaced by copper.....	188
Wire for transmission-lines.....	161
Alumite in Utah.....	42
Amalgam, scraping off plates.....	38
Amalgamated Properties of Rhodesia v. Globe & Phoenix Gold Mining Co., suit decision.....	57
Amalgamating-plates, cause of discoloration.....	219
Amalgamation on the Rand.....	232
American Association for the Advancement of Science, appeal for research.....	225
Committee of mining engineers in England organized for the War.....	868
Geologists in Colombia.....	497
Metallurgy, Western.....	303
American Institute of Mining Engineers, Philip Moore elected president.....	254
Montana section.....	856
Presidency.....	369
St. Louis meeting.....	684
Standard of admission.....	408
American Metal Co. v. C. A. Bentley.....	867
American Smelting & Refining Co. hold metals at cost.....	242
Smelter at El Paso, improvements.....	840
Tests with sulphur and sulphuric acid on soils.....	111
To make chemicals.....	549
Ammonium sulphate.....	713
Ames, George E., obituary.....	687
Amortization and depreciation.....	393
Anacostia copper production in 1916.....	298
Annual labor time for performance of.....	154
Labor v. tax on claims.....	920
Antimony, Chinese.....	312
Deposits of Arkansas.....	738
Discovery near Mokelumne Hill.....	6
Electro-deposition of.....	451
In 1916.....	869
Native.....	845
Appeal, the Miami.....	378
Ditto.....	182
Minority opinion.....	23
Application of cyanamid to phosphate rock.....	699
Are chate-gate and station.....	276
Argentina is not argentite.....	139
Arizona metal production in 1916.....	535
Mining in the north-west part of.....	920
Molybdenum in Hualpai mountains.....	173
Molybdenum occurrence.....	138
State Bureau of Mines and publicity.....	382
Arizona-Tonopah promotion.....	82
Arkansas, antimony deposits of.....	903
Calamine output in 1916.....	284
Developments in 1916.....	156
Arsenical ore, flotation of.....	844
Arsenopyrite in Nickel Plate mine.....	154
Asbestos minerals.....	
Assessment work on Ontario mines suspended.....	
Aurora, Consolidated, Nevada, 1916 output.....	
Australia, coal miners.....	
Electrolytic Zinc Co. new plant.....	
Government mills.....	

Australia (con.)

Iron production.....	Page 196
Mining conditions.....	254
Review of mining industry.....	343
Zinc, imports of.....	358
Automatic ore-feeders v. shovel feeding.....	382
Skips in shaft with rope-guides.....	888
Automobile, uses for.....	308
Trucks, design and operation of.....	53
White, crossing continental divide.....	604

B

Babbitt metal.....	Page 204
Bacon, Earle C., obituary.....	598
Baggage as mine samples.....	717
Ditto.....	722
Fred T. Greene.....	433
Horace Stanton.....	723
Bain, H. Foster.....	727
Bradley Stoughton.....	763
Mining problems of the Rand.....	186
Ball-mills.....	327
A. E. Drucker.....	382
W. E. Simpson.....	507
Barberton mine, flotation at.....	181
Barring-down.....	657
Baruch, Bernard, and the peace scare.....	800
Bateman, G. C.....	514
Baughman, Will.....	90
Method of treating impure tungsten ore.....	49
Bauxite and laterite.....	326
And refractory clay.....	540
Bawdwin mines, geology of the.....	220
Beauchamp, F. A.....	328
Beaver Consolidated at Cobalt cuts the contact.....	295
Beckman, J. W.....	598
Belgian relief.....	180
Ditto.....	663
E. Coppe Thurston.....	468
Bell, Bertram C., obituary.....	704
Belt-driven short centre.....	182
Beneficial effect of grinding with steel balls for flotation.....	103
Victor Zachert.....	576
Otto Sussman.....	327
Bentley, C. A. v. American Metal Co.....	451
Bessemer ore.....	327
Bethlehem Steel Corporation.....	441
Big Jim mine, Oatman.....	873
Big orebodies, method of mining.....	225
Billick, Dan C.....	302
Bismuth, its effect on gold.....	429
Black Hills tin and tungsten.....	441
Black Oak mine.....	441
Black sand.....	441
Blake rock-breaker, the first.....	441
Bland, John.....	441
Ditto.....	441
Tin and tungsten in Black Hills.....	441
Blast-furnace, width of.....	441
Bunker Hill smelter.....	441
Practice in Japan.....	441
Blasting crew, equipment for.....	441
Detonators.....	441
With low-grade explosives.....	441
Blow-pipe determination of minerals.....	441
Blue-Sky law.....	441
Boiler feed water.....	441
Precipitants for salts in water of.....	441
Safety orders of California.....	441
Scale.....	441
Bolivian tin in Chilean smelter.....	441
Tin shipments.....	441
Tin, Pazna district.....	441
Francis Church Lincoln.....	441
Bonanza pocket mine.....	441
Bond issue, the great.....	441
Bonus system in mining.....	441
Tramp Mill-Man.....	441
System in mining.....	441
Boomer for placer mines.....	441
Boone, Charles S.....	441
Borax, source of.....	441
Boykin & Hereford wulfenite mill, Mammoth, Arizona, flow-sheet.....	441
Brayton, Corey C.....	441
Dredging for gold on Seward peninsula, Alaska, season 1916.....	441
Brazil, manganese in.....	441
Mining industry in.....	441
F. Lynwood Garrison.....	441
British Columbia mineral output in 1916.....	441
Practice in Japan.....	441
British companies registering abroad.....	441
Brockunier, S. H.....	441
Some pertinent questions.....	441
Broken Hill, flotation at.....	441
Potter process at.....	441
W. E. Simpson.....	441
Brooks, E. F.....	441
Platinum in California.....	441
Prevention of misfires.....	441
Brown, David H.....	441
Notes on the metallurgy of copper.....	441
Death of.....	441
Bruh, Paul T.....	441
What makes a good flotation oil.....	441
Bubbles, millions in.....	441
Buffington, Justice, minority opinion in Miami appeal.....	441
Building of ships.....	441
Bunker Hill Consolidated Mining Co., mine.....	441
Bunker Hill & Sullivan, change-house.....	441
Smelter.....	441
Bureau of Mines rescue car.....	441
Bureau of Standards—screen-scale.....	441
Burma as a tungsten producer.....	441
Burning dynamite.....	441
Burrell, Alexander, obituary.....	441
Business at end of January.....	441
Not as usual.....	441
Butler, G. M., on mining investments.....	441
Butte, fire in Speculator mine.....	441
Mine fire.....	441
Editorial.....	441
Mines' creed.....	441
Butte & Superior annual report.....	441
Flotation oil.....	441
Editorial.....	441
Zinc concentrate.....	441

EDITORIAL

T. A. RICKARD, Editor

USERS of the flotation process are advised not to be unduly disheartened by the Supreme Court decision in the Hyde case. We are informed that a way has been found for operating the process outside the limitations defined by the Court.

MISFIRES are discussed in this issue by Mr. Edward Higgins, lately of the U. S. Bureau of Mines, and Mr. Walter S. Weeks, of the University of California. To these gentlemen we are indebted for information of a directly practical kind.

READERS will note that the financial review of 1916 is written by Mr. Osmund Phillips, editor of *The Annalist*, which is the financial supplement to the *New York Times*, the leading newspaper of the United States. We are pleased to say that this review came to us in exchange for a review of mining in 1916 contributed to *The Annalist* by the editor of the MINING AND SCIENTIFIC PRESS.

LEGISLATION authorizing co-operative trade agreements is the subject of a letter from Mr. W. L. Saunders. With the purpose of such an agreement we are in hearty accord. As Mr. W. C. Redfield, the Secretary of Commerce, has said: "Economic alliances may come and go; tariff policies may change; but greater things will determine our place in the world. Combinations and anti-trust laws are relatively trivial. If we will waste, we cannot win."

WHILE the production of copper in the Lake Superior region in 1916 is estimated at 260,000,000 pounds, it is said that it would have been 40,000,000 pounds more if Sunday had not been set aside as a day of rest. This is a fallacious argument, for it assumes that the miner would have produced as much copper in the 52 days that were set aside as in an equivalent number of other days during the year. Our own experience has been that if a man works without a break, he is likely to lose his efficiency, even if he does not become incapacitated by illness.

GRINDING-MILLS are discussed by Mr. C. T. Van Winkle in this issue, with particular reference to the episode at the Inspiration mine. We believe our correspondent to be an independent engineer, not interested in the manufacture of any machine, and that is why we are glad to publish his letter. It is a rule of this paper not to publish matter emanating from the manufacturer, because he has the advertising pages at his disposal and

because his view concerning the machines he makes are likely to be as prejudiced as his views concerning the machines that are made by his competitor. The opinions, and more particularly the experience, of any independent engineer or manager of mines in the use of any machine are welcome because they are likely to prove useful to others engaged in mining.

UNDER 'Discussion' we publish a courteous and disarming protest from a member of the Mining and Metallurgical Society of America against some comment recently appearing in these columns. In reply, we suggest that short of a general revision of the land laws by a competent commission, it is undesirable to repeal the extra-lateral right, now in force over so large a part of the mineral regions, and to confine immediate reform to the cancellation of 'discovery' as a preliminary to location, but not to patent. The second letter under 'Discussion' happens to refer to this very point. We have also received a letter from Mr. Horace V. Winchell on the subject, expressing strong disagreement with our views. His letter unfortunately arrived too late for inclusion in this issue.

ACCORDING to the best information, the British embargo on trade in copper, except under license from the Ministry of Munitions, is intended to prevent the use of the metal for non-essential purposes, such as the manufacture of brass bedsteads, household fixtures, and electric-light fittings, and to economize labor by diverting it from such non-essential work to other channels more immediately useful for the purposes of the War. It is stated also that an organization has been established for returning spent cartridges, for re-use or re-melting. In this and other ways great economies are being effected in the consumption of metals for munition purposes.

MEXICAN affairs at the beginning of 1917 are no more hopeful than a year ago. The Joint Commission has failed. We are told one day that Mexico has the moral capacity to become master of herself and the next we hear that Villa and his followers are capturing towns or destroying railways without serious opposition from the *de facto* government. Among mining men it is stated with a confidence fed probably by much wishing that the Carranza régime is on its last legs and that American intervention is at hand. Surely, they say, if Villa wins control of northern Mexico he will not be recognized by Washington, for he is an outlaw and a murderous raider. Meanwhile it is not ungenerous to suggest that President Wilson might look

upon the Mexican affair as more within the scope of his responsibility than the European conflict. The Mexican mess ought to be set right before the United States undertakes to act as peacemaker overseas.

REFERRING to the South African government's invitation for tenders to exploit mining claims in the Far East Rand, it is interesting to note that the Brakpan Mines Company made an offer for 1812 claims adjoining its present property, agreeing to spend £850,000 and to make a large increase in the existing milling plant. In addition to the 10% profit tax, the Brakpan company will pay 5% on any profit made during the next five years and thereafter a further royalty on a sliding scale, the minimum being 12½% per annum. Another tender, by the Central Mining group, was accepted on 650 claims, covering the Modderfontein farm, to be incorporated with the adjoining Cloverfield and Rand Klip properties, it being provided that the capital shall be raised to £1,200,000 and that a royalty of 10% shall be paid in addition to the 10% profit-tax. No American tenders were received. Meanwhile the State Mining Commission at Johannesburg is hearing evidence concerning the advisability of the State operating mines on the Rand on its own account.

IN reply to a Christmas cablegram to Mr. H. C. Hoover, informing him of the starting of the Belgian Kiddies fund, as announced in our issue of December 23, he replied as follows:

"Please convey to my American professional colleagues my gratitude for the very great personal compliment which I feel; in generous gifts to this work the Belgian Relief Commission has not only to be grateful to the American engineering profession for financial support, but also for the large body of men who have made the work possible; it has not been the work of any individual, but to the largest degree due to American engineers who have filled these ranks from the beginning and have brought to bear upon it not only their unique capacity for pioneer organization, commercial adaptability, and ability to overcome physical obstacles, but also the fineness of courage, devotion, and idealism which are the daily demands in this service and are to be found to such a degree in no other profession; we have had not only from the mining engineers, Honnold, Rickard, Shaler, Brown, Young, Thurston, Broderick, Fletcher, Smith, and Bain, but also from our brother engineering profession in America we include with equal pride the service of White, Holland, Hunsker, Crosby, Bates, Lucey, Connett, Chadbourne, Heinemann, Hulse, McCarter, Tuck, Gade, Gay, and Hunbert. It has been an engineer's job and has been done in an engineer's way; its recognition and support by our brother engineers is precious to us all."

We are informed that there has been a widespread response to the original circular, but only a few of the wealthier engineers have contributed as generously as had been hoped, the largest single contribution being

for \$10,000. It is hoped that some of the wealth so easily made during 1916 by those fortunate in their speculations may be diverted to the crying necessities of the little people in that downtrodden and most unhappy country that has become so unwillingly the scene of cruel warfare.

The New Year

The choice of a particular day to mark the start of another of the earth's flights on its orbit round the sun may be arbitrary, but the sense of an ending and of a beginning is felt by all of us. We turn a page; we close an account; we look forward to a new twelve months of life and endeavor. What 1916 has meant to the mining industry we attempt to tell on a following page; what it has meant to this professional paper we are glad to say in a few words. After two or three years of slackness the MINING AND SCIENTIFIC PRESS has re-taken a firm hold on the support of those actively engaged in mining. We are proud to say that 2615 new subscribers have been added during the year. This is an astonishing gain and affords no small measure of encouragement to those that have tried to make the paper useful. Many of the new subscribers are old friends who have returned to our support. To them we give the silent hand-shake of men that know each other. To the new members of our clientele we extend a hearty welcome, with the invitation to make use of us as a source of information or as a means of obtaining it from others. This paper is not the product of a machine and it is not run by a syndicate; we believe in the kind of journalism that is human and personal; if the editor is in control it is not to manage a slot-machine for advertisements but in order to be independent. It is so human to err that the least a man can do is not to add subserviency to the other factors that produce error. The aim of this paper is to promote the best interests of the mining industry and to serve the highest traditions of the mining profession. We make mistakes often—any outspoken critic is bound to do that—but we would like our readers to understand that an intelligent disagreement is always more welcome than a careless concurrence. This means that letters criticizing any expression of opinion or statement of fact appearing in our pages are given prompt publication. We are old enough to know—for were we not founded in 1860—that such letters are usually more interesting to our readers than those that endorse the editor's views. We hope that the 'Discussion' department will be used freely in 1917 as a means of creating sound opinion on matters important to the industry and to the profession. Therefore we repeat here what we have said often in conversation with the younger engineers: the writing occasionally of a technical article is an excellent method not only of emerging from the 'and others' and the 'also rans,' and of making mental acquaintance with men at a distance, but of crystallizing amorphous knowledge and of discovering what is not known. The first step in science is to separate what we know from what we do not know. Any

engineer that undertakes sincerely to describe a process or explain an ore deposit will learn more by the effort than anybody that reads what he has written. No mental discipline is more valuable to the technical man than the attempt to record his ideas or his experience in writing—for publication. We add the last two words because the consciousness of possible criticism is a necessary spur to careful performance. However, the writer, particularly if he be inexperienced, should remember that he has a friend at court in the editor, who stands between the writer and the reader so as to make the relationship pleasant for both. We also invite items of mining or metallurgical news. Upon our friends in the field we depend largely for authentic information concerning current developments. The sifting of such news is beneficial to all concerned. Only those behind the scenes can know how difficult it is to obtain accurate data concerning the progress of events in a speculative industry. Another thing for which we ask is friendly criticism—constructive, of course, and helpful, but none the less frank. In a sense every subscriber is a shareholder, for the opinion of the reader of such a paper as this is of more moment than that of a shareholder that is not a reader. Please assume that we aim to be of maximum usefulness; that we want to be of service to as many as possible and of disservice to as few as possible; that we aim to be interesting while being also truthful—this is our policy. For such plain speaking we offer no apology. Straight talk is best among friends. In the year ahead of us there will be many problems to face; the effect of the War and the anticipation of Peace will alike cause market perturbations; the relation of labor to capital is likely to undergo painful adjustment; the speculation in mining shares will be so intense as to stimulate illegitimate methods, both of financial promotion and of professional participation; the year 1917 is going to test character. May it prove that the mining engineer is not only a technician and a business-man but a citizen and a gentleman.

Minority Rights

A suit has been brought by Dodge Bros., as minority shareholders in the Ford Motor Company, to compel Mr. Henry Ford to distribute a reasonable portion of the company's \$55,000,000 surplus in dividends and to restrain him from investing or otherwise using the company's funds in ways that do not meet with the approval of the plaintiff shareholders. This action has aroused keen interest and the injunction granted by the court of first resort, which ordered a further hearing on the merits of the case, is likely to accentuate interest in the matter. It comes within our purview because Mr. Ford proposed to use the accumulated cash in building a smelter on the river Rouge near Detroit. Two questions are involved: (1) Is the diversion of the money for this purpose an abuse of the usual discretion allowed to directors? And (2) does such business come under the charter rights of the defendant corporation? The Dodge brothers main-

tain that Ford's policy is to benefit humanity rather than to make money, having made much more than he needs. The controversy, it seems to us, narrows itself to the question whether Ford is acting as a trustee for all the shareholders or doing simply what pleases the largest shareholder—himself? Problems of this kind arise frequently in the administration of mining companies and most of us can readily recall instances in which a company dominated by an individual or by a small group has been administered to suit his or their plans in directions outside those for which the company was organized and in schemes alien to the purpose for which its capital was subscribed by the shareholders. In such matters the law affords but little protection to the minority shareholder, because any effort to assert himself involves costly litigation the outcome of which is doubtful owing to the ease with which financiers can hide their tracks. Public opinion is the main deterrent, even if it be feeble in its impact upon the prestidigitateurs of finance. In England the Companies Acts give protection to the lonesome shareholder but it must be confessed that the check on *finukerij*, as they call it on the Rand, is not enough to prevent the unscrupulous promoter or even the more considerate 'big house' from 'putting it over' the public. Laws derive their force from public opinion. In no sphere of industrial activity is it so necessary as in mining to stimulate and support a high standard of decency in matters that affect the responsibility of directors to the owners—that is, the shareholders—of property.

The Small Miner in 1916

The year 1916 will be long remembered by the small mine-owner and operator as a period of unusual prosperity, for it has been a year of rapid wealth-getting to many of these as well as to the greater concerns whose output runs into the millions, and whose worries and responsibilities are correspondingly greater. It has been a year teeming with unexpected possibilities, and many there are who saw in these new opportunities the nearest approach they had even known of that elusive fortune which had been sought eagerly and long. In numerous instances the vision of the money goddess came true; in many others it vanished, as before, and with it much of the hope that had been quickly lifted from the depths, for the market fell and opportunity was gone. The sudden and unprecedented rise in quicksilver, the great demand for tungsten, antimony, chromic iron, magnesite, and manganese urged the small mine-owner, lessee, and operator as he had never been stimulated before to produce the minerals and metals for which the market called urgently and ever in greater amount, with a consequent daily increasing price. Hundreds of men—brokers, merchants, and others, most of whom had never seen a mine—plunged boldly into the swirling stream and in most instances they, or their clients—usually the latter—were engulfed in the maelstrom of speculation from which some escaped, poorer if not wiser men.

One noticeable feature of this modern boom in mines

was the nonchalance with which men of the Rufus J. Wallingford type offered for sale the mining property of others without the slightest authority from anyone, to say nothing of the owner. One mine, a quicksilver property of merit, was offered about San Francisco by no less than seven different men and their numerous assiduous satellites, each of whom claimed to hold an exclusive option to purchase the mine in question, though no option on the property had been given by the owner to anyone. The price asked for this property ranged from \$40,000 to \$240,000.

The demand for quicksilver was so unexpected and so insistent that the price rose rapidly from \$32 per flask late in the fall of 1915, to \$300 a few weeks later. Was there unusual activity in quicksilver mining? There was, and it was prompt, vigorous and—in some instances—disastrous. However, the rapidity with which the demand was satisfied 'knocked the props' from under the market, and the price came down even more rapidly than it had risen. Today the quicksilver industry of California is moving along quietly and satisfactorily, and in a dignified manner, with the price of the metal at somewhat over a dollar per pound. Scarcely less stirring was the effect of the rapidly soaring price for tungsten ores. Two or three years ago the owner of a tungsten property, either large or small, considered himself fortunate if he could dispose of his 60% ore at \$450 per ton, but during 1916 the price vaulted to \$85 per unit—a price that promptly brought even cabinet specimens into the market at \$4 per pound. It also stimulated prospectors and miners to use their utmost endeavor to grasp at least a little part of the millions of dollars that seemed to be fluttering in the air within the easy reach of any who would make an effort. But tungsten, like quicksilver, soon glutted the market, and it was this, together with the more important fact that Eastern buyers evidently had some sort of understanding, that resulted in the downfall of the rickety price of WO₃, and put a sudden stop to the further extension of all but the absolutely legitimate development of the industry. Added to the depreciated market was the further deterrent of the disappointing development of a number of unusually promising prospects—rich at the surface, but quickly petering in depth. So, tungsten, like quicksilver, is moving along soberly at about \$20 per unit but not without hope for a somewhat better price in the near future—peace or no peace. Chrome, manganese, and magnesite shared in the general good fortune of the year, but in a more moderate degree than quicksilver or tungsten.

There was one peculiar phase of copper mining that was without precedent in a time of unusual activity in the demand for and production of the metal. This was the inability of the small copper-mine owner, or lessee, to sell his ore. While the great copper producers were being worked under ever increasing pressure, the smelting facilities were inadequate to treat the enormous tonnage of ore offered. Much of the ore was being smelted under contract at the custom reduction works and as the

capacity of the furnaces was taxed to the utmost, the small producer could not be accommodated; so he had to stand aside and see the big operators enjoying an unprecedented prosperity in which he, the small producer, had no share. But the working miner—the man that is the mainstay, after all, of mining, whether it be a little property, employing only two or three men, or one of the great enterprises that numbers its employees by thousands—has benefited directly by the expansion of mining enterprise in 1916, for there are few places where wages have not been increased from 10 to 30%. Even the managements of gold mines, which as a whole were not benefited by the unusual activity of the year, but on the other hand were adversely affected because of the rise in price of supplies, voluntarily increased the wages of workmen, perhaps not so much from philanthropic motives as from a desire to discourage their best men from migrating to the copper and zinc mines. Thus wages were raised to the direct advantage of the miner, at a time when he needed it, to compensate for the higher cost of living.

Metal Mining in 1916

The year now near its close has been abnormal. Mining has been conducted under the stimulus of a feverish market, the future of which no man can foresee.

This review does not concern itself with ferrous mining, which is a subject apart, yet it is proper to refer to the growth of a basic industry. The production of pig-iron in the United States during 1916 is estimated at 40,000,000 tons, an increase of 11,000,000 tons as compared with that of the preceding year. This country now produces more than half the pig-iron of the world—a fact that may prove more important in the long run than our present hoard of gold. Long ago Solon told Croesus, the king of Lydia: "Gold will never save you; if your neighbor has more iron than you, he'll conquer you and take your gold." He referred to weapons, and in these later days iron may represent munitions, as well as the strong foundation of peaceful industry. We are producing annually \$800,000,000 worth of iron as compared with a little less than \$100,000,000 worth of gold. Our production of gold in 1916 may have increased slightly, but the value of the gold dug out of the earth is insignificant compared with that imported by us in exchange for commodities and securities. We have now over two and a half billion dollars of gold in this country, and if our foreign trade continues for another year at the existing rate we shall have four billions, or half of all the visible supply of gold, outside the arts, in the world. All the gold extant could be contained in a 28-ft. cube. The world's annual output is only \$450,000,000, and two-thirds of it is mined under the British flag.

Owing to the consumption of the base metals in the manufacture of munitions there has been a great expansion in the mining of copper, lead, and zinc. The vagaries of the market can be summarized as follows, in cents per pound of metal:

Dec. 1, 1913 Dec. 1, 1915 Dec. 1, 1916 1916

Copper	14.25	19.75	34	Early in May, 29.5; in July down to 25
Zinc	5	18.12	13.25	Down to 8.37 in August; rising since
Lead	4	5.75	7.25	Up to 8 in March; sagging to 6 in August

The 'peace scare' just before Christmas caused a drop in the prices of copper and zinc, to 31 and 9.75c. respectively, as if to warn us of what may happen if hostilities cease in Europe. The rise in the quotation for lead, to 7.50c., is less significant, as it is the price fixed arbitrarily by the American Smelting & Refining Company.

Copper, owing to the big purchases made by the Allied governments, has had a spectacular rise wholly unforeseen a year ago. At the present time the production of this country is sold seven months ahead; in other words, the copper to be produced by the United States during the first half of 1917 is sold already, at prices ranging from 24 to 32 cents. Production has been pushed by all the great mines so as to make the most of the extraordinary market, and it became a question early in 1916 whether the refinery capacity could keep pace with the expanding output of blister copper. That has been nearly done, so that today the American refineries can treat 1,200,000 tons per annum, which is about the rate of gross production anticipated within six months. In 1913 the world's production of copper was 1,104,500 short tons, of which the United States contributed 614,400 tons. Therefore our production will shortly be double what it was three years ago. Our export for several years before the War was 350,000 tons, of which Germany took 100,000 tons, increasing to 153,000 tons in 1913, when preparations for War were being made. The market is now in an unhealthy condition and is causing big gambling in the shares of copper-mining companies, the quotations for which have shown tremendous appreciation:

	July 30, 1914	Nov. 18, 1916	Dec. 23, 1916
Anaconda	\$25	\$104½	\$81½
Inspiration	15	74½	55½
Utah	46	130	98½
Nevada Con.	10½	33½	23½
Miami	17½	48½	37½
Ray	16½	36½	26½
Chino	32	74	53

The heavy drop that followed the 'peace scare' is indicated by the quotations on December 23.

Making allowance for pre-War contracts, the mining companies have obtained an average of about 25 cents for their metal in 1916, as compared with 15½ cents in 1913, so that their profits have been enormous, but, in so far as the present speculation in shares is based on the expectation of the persistence of the present price of copper, the position is precarious. In September Great Britain, for herself and her allies, purchased in one transaction—the larger part of the entire American production of copper to be made during the first half of 1917. The deal involved 480,000,000 pounds at 25½ cents. Since then the price has risen 9 cents, to 34½, so that it is quite reasonable to surmise that part of this

purchase may be re-sold on our market, in anticipation of lower quotations. Speculation in copper has spread from the bucket-shop to the Treasury.

Zinc rose to 27 cents per pound in 1915, and was on the decline at the beginning of 1916. This relapse continued until the price had fallen to 8.37 cents in August, but since then the demand for 'spelter,' as it is known in the metal trade, has been in sympathy with the rise in copper, with which it is alloyed to make the brass used in munitions and other warlike apparatus. Therefore the market has improved and stands now at a price 120% higher than in the days before the War. The almost complete cessation of production in Australia during 1914 and 1915 caused a big drain on the American supply, and accounts for the excited market in the second year of the War; since then the British have consolidated their position and made arrangements for a large domestic production the full effect of which will be felt when the world is at peace once more. Australia produces just the tonnage of zinc that Great Britain consumes normally. Since 1914 the number of retorts in action in the United States has been nearly doubled, the increase of zinc output being equal to the whole American production in 1913.

Lead also has had an eventful record, stimulated by the use of the metal in shrapnel and other munitions. Normally we produce only about 10% more than we consume, so that the cessation of the War demand threatens a big drop. However, any such suspension of demand for the metals is dependent on the course of events that nobody can foresee. Whether peace ensues in six months or two years is not predicable; therefore the business of production rests today on an extremely insecure basis. While the drop in prices may not take us back to the pre-War quotations, it is to be noted that part of the profit to be obtained by an incomplete recession to the basis of July 1914 will be absorbed in the higher cost of production.

This is an important factor. While the normal cost of producing copper, for example, in the United States may have been 10 cents per pound before the War, it is safe to say that it is 13 cents now, and it will go higher as the present conditions persist or become worse. Not only is the expenditure for labor, supplies, and machinery rising steadily in the effort to distribute the mine-owner's abnormal profit among his various coadjutors, but the richest and most accessible orebodies are being exploited in a hurry in order to take advantage of the extraordinary market. This means not only the exhaustion of the better grade of ore, but such a serious deterioration in the physical welfare of the mines as will require the expenditure of time and money in order to restore them to normal efficiency. In the zinc business, it is estimated that the cost of production, which before

the War was close to the market-price of 5 cents, is now about 7 cents per pound, owing to the concomitant rise in labor and materials. This increase also threatens to be accentuated for reasons similar to those recited as affecting the winning of copper.

Some of the secondary metals have shown fluctuations even more violent than copper or zinc. The prices given herewith represent the quotation per unit, that is, 1% per ton, or 20 pounds, at New York:

quantity of tungsten. Existing prices reflect this ratio of efficiency.

Two other metals remain to be reviewed:

	Dec. 1, 1913	Dec. 1, 1915	Dec. 1, 1916
Silver, per ounce	57.76c.	56.12c.	75½c.
Mercury, per flask	\$40	\$105	\$80

Silver was not affected by the War until it became evident that this precious metal would be required in-

	Dec. 1, 1913	Dec. 1, 1915	1916	Dec. 1, 1916
Antimony (Sb)	\$2.00	\$8.00	In March, \$9	\$2.80
Tungsten (WO ₃)	7.00	45.00	End of February, \$85 Down to \$30 in July	18.00
Molybdenite (MoS ₂)	4.50	30.00	End of January, \$28 Middle of June, \$22	36.00

Tungsten is quoted in terms of a concentrate containing 60% tungstic oxide and molybdenite in terms of 90% molybdic sulphide.

Antimony has been quiet as compared with 1915, when the price rose to 40 cents per pound, or \$8 per unit, in December. This rise continued into 1916, culminating at 45 cents in March, when the effect of shipments from China and Japan, added to the quick increase in our own domestic production, caused a collapse. At the end of June the price was 20 cents, the decline continuing to the present quotation of about 13 cents per pound. Antimony is used in making 'hard lead' for shrapnel bullets and is therefore a 'war baby,' but of late shrapnel has given way to high-explosive shells, lessening the demand. This metal is imported so cheaply and of such good quality from China that the mining of it in this country has been discouraged. The rise in price led to the re-opening of small mines in California, Alaska, Idaho, and Nevada, and the operation of small smelters at Los Angeles, San Francisco, and Seattle. It is possible that the revival of prospecting for antimony may lead to the discovery of deposits large enough and of methods efficient enough to lay the foundations of a new industry.

The interruption to shipments from abroad has created a demand for the special metals used in steel-making, and has stimulated the search for the minerals containing them. There has been a lively market for tungsten, molybdenum, manganese, and chromium. Whether the search for such ores will have enduring results is an interesting question. It gave a hectic flush to 1916. Tungsten, which is used to make the high-speed tool-steel required in the munition factories, has had a career even more exciting than that of antimony. From a pre-War price of \$6.50 per unit, the quotation rose in February 1916 to \$85 per unit, or \$4.25 per pound. This was due to wild speculation, for the price dropped quickly to about \$70, and thereafter began to decline until in July it had reached \$30, where, however, it did not stay, falling to \$17 in September, since when the market has been fairly firm. Molybdenum, another ingredient in the hardening of steel, has advanced steadily, its cheapness being measured by the fact that a given quantity of it will harden twice as much steel as the same

creasingly for subsidiary coinage and to replace the gold being withdrawn from circulation. The curtailment of production in Mexico might have been a further factor if the increased output of silver as a by-product in the mining of copper and other base metals had not more than compensated.

In the middle of February quicksilver rose to \$300 per flask of 75 pounds, but this quotation was momentary, a sharp break being followed by a decline so that in May the price had receded to \$100, and in June to \$68, since when there has been a slight recovery. Undoubtedly an attempt was made to corner the supply, but it failed ignominiously when the British government lifted the embargo on exports from Europe, admitting shipments to New York from Spain and Italy. Moreover, the stocks of quicksilver held at silver mines in Mexico that had substituted cyanidation for amalgamation came upon the market as soon as the price was trebled, and sundry gold-mining companies likewise took advantage of the abnormal price, while others exercised the greatest economy in its use. The War, of course, played a part both in the rise and fall. Mercury is used in making fulminate for detonating caps, a supply of which is manufactured by the Du Pont works for the Allies. When the price of quicksilver soared prohibitively in this country, the British government called upon the Rothschilds, who control the European production, to correct the artificial condition created by American speculators. The lesson was salutary. Since then nobody has cared to gamble. This is another example of the manner in which the metal markets are subject to the exigencies of the War, and to the action of individual Governments endeavoring to facilitate their own warlike operations. After all, the normal production of quicksilver in the United States—20,000 flasks—is so small that any increase in production is felt at once.

A rise in the price of a metal or a mineral to ten times its normal price gives economic value to the discards of earlier times. When quicksilver and tungsten were being kited there was a great rush to work old dumps and to extract the filling of old stopes all over the West. The tungsten 'boom' in Colorado was typical. There, in Boulder county particularly, the ferberite, or iron tung-

state, that had been cursed by the mill-man because it interfered with the amalgamation and concentration of gold and silver ores, and that had been thrown aside, without scrutiny, was put into sacks by enterprising collectors and sold at a handsome profit. Idle mines became valuable for their abandoned dumps or were re-opened for the tungsten ore yet to be mined. Small boys made an easy gain from the pickings, and 'high-grading,' the miner's euphemism for petty larceny, became fashionable. The aftermath of all this was a recognition of the tungsten minerals, a successful designing of methods for concentrating them in the mill, and such a study of the economic geology of the district as will furnish guidance for further exploration. In California the search for scheelite, the tungstate of lime, received a similar stimulus. It is a notable fact that the biggest dividends paid by any metal mine in California during 1916 came from a tungsten property, the Atolia, in San Bernardino county. This enterprise luckily was a going concern when the 'boom' began, the mine having been worked profitably for several years, so that it was in a position to make the most of a favorable market. The lessees on the property rushed their production and the company built a new mill. Here also theft became rampant. It is even asserted that representatives of the steel-making manufacturers sent agents to Atolia to buy 'high-grade' or stolen ore.

When quicksilver rose suddenly to \$300 per flask, as against the \$40 to which the price had sagged in former years, the haste to find it led to strange doings. California, Nevada, and Texas enjoyed the excitement. Old furnaces were dismantled for the liquid metal with which the brick was soaked, old dumps were sorted and marketed, abandoned workings were penetrated. In some instances hasty concentrating apparatus was devised and in others the new flotation process was tried. Although the collapse of the market came so quickly several metallurgical improvements can be chronicled among the sequelæ of the boom, such as the introduction of the Cottrell tube for condensing the sublimate and the application of flotation to cinnabar. Several mines changed hands, and with them considerable sums of money, but most of these have been closed already. The flurry has attracted attention to the nimble metal and has led to sundry scientific investigations into the quicksilver deposits of the coastal region, so that information has been collected that will be utilized in fresh exploratory work.

The foregoing paragraph suggests that the whole story of mining in 1916 is not told by statistics, whether of the metal-market or of the stock-exchange. The stimulus to the search for ore, the re-opening of old mines, and the invention of new methods are consequences that will outlive the ephemeral results. The development of a copper mine, more particularly the large-scale operation on which the industry increasingly depends, is not the work of a day or even a year. The high quotation for the metal has led to the intensified exploitation of existing mines rather than the starting of new ones, because the more sagacious among men realize that the abnormal market

may not last long enough to bring a new enterprise to fruition. Nevertheless conditions have favored increase of energy in developing mines recently started and in exploring new ground belonging to the older properties. One of the striking episodes of the year was the uncovering of an extraordinary deposit of rich ore in the United Verde Extension mine, at Jerome, Arizona. The first company to work this prospect was organized in 1894 and was re-organized in 1902 and again in 1912. In 1913 the mine had about 5000 feet of underground openings and showed a little ore on the 800-ft. level. This ore contained 2% copper, with 1 oz. silver and 3 dwt. gold per ton. At the end of 1915 a big bonanza was uncovered on the 1400-ft. level. Early in 1916 this orebody was proved to be a mass 250 ft. long, and equally wide, of 17½% copper ore. Shares that had sold at 50 cents in 1915 rose to \$46, making many men wealthy. For example a well-known engineer bought \$15,000 worth of stock, and within twelve months he emerged a millionaire. This is one of the authentic romances of mining, and it would be wholly delightful if it were not being used now as a lure for the simple-minded speculator.

Another notable episode was the intensified exploitation, or 'gutting,' of the wonderful mass of ore in the Kennecott mine, in Alaska. This was removed and shipped from Cordova to Tacoma at the rate of 5000 tons per month; indeed the supply exceeded the capacity of the Tacoma smelter, so that shipments of crude ore from this mine were passed to the Garfield smelter, in Utah. The output for 1916 must have been about 55,000 tons of metal. The cost is said to have been only 5 cents per pound, for much of the ore assayed 60%, which would mean that a ton of such ore contained 1200 pounds, or \$300 worth of metal, yielding a profit of \$240. The earnings of the Kennecott company were stated to be \$1,000,000 per month. This excused the financial legerdemain called a 'merger' whereby the Kennecott Copper Company was consolidated with the Braden Copper Company and sundry holdings of the Guggenheim Exploration Company in other copper mines. Statements have been made that the Kennecott has a five-years supply of ore, and the public is allowed to infer that it will be of the same extraordinary richness.

The breaking and removal of ore is only half the work of 'mining,' which must be supplemented by the extraction of the valuable metals, namely, metallurgy. In this department the year 1916 has seen at least two far-reaching developments: the flotation of oxidized ores and the electrolytic refining of zinc. The flotation process may be defined as a method of concentration in which froth is made by the introduction of air into water modified by oil or some other contaminant that lowers the surface tension so as to cause the bubbles constituting the froth to last long enough to float the particles of metallic sulphides in a pulverized ore. The wide application of this process is contemporaneous with the War, for it had made but little headway in the United States up to August 1914. During 1915 a rapid extension of flotation took place and in 1916 a still greater advance was

recorded. The Inspiration and Anaconda companies are each treating from 15,000 to 18,000 tons of copper ore daily by this process, and it is safe to say that 30,000,000 tons of ore per annum is being concentrated by flotation in the United States at the present time. This is truly a 'revolution' in metallurgy, for the scope of the process is proving as much wider than that of cyanidation as cyanidation was more widely applicable than chlorination. Since the introduction of the cyanide process on the Witwatersrand there has been nothing so epoch-making as the application of the frothing process to the copper ores of our West. Moreover, the same process has been used successfully on silver ore in Mexico, on gold ore in Nevada, on zinc ore in Montana and New Mexico, on lead ore in Missouri and Idaho. The process succeeds exactly where water concentration failed, namely, in saving the flakey slime inevitably formed when sulphides of highly developed cleavage are crushed minutely. It is exercising a tremendous influence on mining, not only in aiding the profitable exploitation of low-grade ores but in enabling the metallurgist to beneficiate the zinc that is associated with the other metals and that formerly was regarded as of negative value because it hindered the separation of those other metals to such a degree as to warrant the smelters in imposing a penalty, which was graduated in accordance with the proportion of zinc present in the copper, lead, or precious-metal ore, as the case might be. The amount of oil or other modifying agent has been reduced in quantity, to a fraction of a pound in some mills, until it has become a minor item of cost. At the same time the improvements in fine-grinding machines have expedited the preparation of the ore so as to permit of further economy. The cost of concentrating a low-grade copper ore, on a large scale, by flotation, including the crushing and grinding, has been diminished to 45 cents per ton. The product is a concentrate, of which so much is being made as to cause a decided change in copper smelting, for it necessitates the increased use of the reverberatory furnace and additional emphasis on the roaster equipment. This development in flotation is to be credited in part to 1915, but the successful treatment of oxidized ore is a feature of 1916. Previously it had been supposed that sulphide ores alone were amenable to flotation and that oxidized ores were not only recalcitrant to the process but that they interfered with the successful recovery of the sulphide portion of the mill-feed. It has been demonstrated in the course of 1916 that the oxidized ores of copper and lead can be treated by flotation. This is done by sulphidizing, or coating with an artificial sulphide, so as to render the oxidized mineral amenable to flotation.

Another metallurgical development that has come to fruition in 1916 is the extraction of zinc by the electrolytic process. This had been done previously on a small scale in Ontario and in California, but the completion of big plants at Great Falls in Montana and at Trail in British Columbia, besides another in course of construction at Garfield, in Utah, has made the process an important factor in both the metallurgy and the trade of

zinc. The plant at Great Falls, work on which was begun on December 13, 1915, is now producing 100 tons of spelter per day; that at Trail, for which ground was broken in October 1915, is producing 70 tons daily. In both establishments the process that is used depends upon the oxidation of the sulphide by careful roasting, the leaching of the oxide and sulphate of zinc in a sulphuric acid solution, the oxidation and precipitation of the ferrous oxide by manganese di-oxide, and the purification of the solution—removing its copper and cadmium—by means of metallic zinc, and finally the electrolysis of the purified solution in the presence of an aluminum cathode and a lead anode, yielding a metal of 99.98% purity. The cheapness of the process depends upon the cost of the electricity, which at Great Falls is obtained from the Missouri river and at Trail is drawn from the Columbia river. Where electrical energy is obtainable for \$15 to \$20 per horse-power year, on a 100% load-factor, this metallurgic method should prove economical as well as highly efficient. It promises to supersede the old retort method of Belgium and Silesia, and to provide the trade with a spelter of exceptional purity. It is important to note also that the electrolytic process brings low-grade ore within the economic limit. Whereas the retort-smelters afforded a market only for a 50 to 55% concentrate, the Great Falls plant is purchasing concentrates containing as little as 35% zinc. Indeed, the low limit is 30%, which means about half zinc-blende, the mineral averaging 67% zinc when pure. Zinc is a metal that is usually found in close association with other metals; formerly it was so detrimental to the treatment of complex ores that it was heavily penalized by the smelters and other ore-buyers. The customer had to pay 50 cents per unit on an ore containing over 5% zinc. Now the zinc in such an ore is separated and treated so as to yield a valuable by-product. This will tend to stimulate the production of metal, of which there will be an over-supply, followed inevitably by a decline in price. The galvanized trade will not be taxed as heavily as it is now by the high price of zinc and only those that can mine and smelt it most economically will be able to survive the growing competition.

The economic conditions now prevailing are not favorable to gold mining, except in so far as the accumulation of capital leads to new enterprise. The value of gold, although fixed by convention, has depreciated considerably of late, as proved by the fact that a given weight of it will buy 30% less of the principal commodities than a year ago. The cost of supplies and machinery, more particularly the use of man, the essential machine, has risen 25 to 33%. A higher rate of wages has been forced upon the managements of gold mines because the base-metal mining companies have granted a raise to their employees and also because the increasing cost of living leaves the workman a diminishing margin on the safe side. Labor troubles have been few, mainly because sagacious managers have anticipated the inevitable demand, but re-adjustment after the War is sure to involve friction and is anticipated with misgiving.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Mining Law Revision

The Editor:

Sir—Your criticism, in the issue of December 9, of the procedure of the Mining and Metallurgical Society of America in respect to the work that it has done and is doing in reference to a revision of the United States land laws as they affect mining locations, hardly seems to the writer to be in accord with the facts or with your well-known fairness in discussing matters relating to the mining profession.

Attempted ridicule suggests the lack of potent argument, and your editorial would be taken more seriously and be more useful if you would point out wherein the M. & M. Society was in error and in what manner its object, if that object is meritorious, could better be attained.

You must admit that the coal, oil, and metal miners have had some serious and just complaints, that the prospector has felt that his lot was becoming a hard one and that every mining society and organization in the country has expressed itself as believing that some alterations would be advisable.

The idea that something was wrong did not originate in the M. & M. Society nor do any of its members think so or feel that they know all of the remedies to be applied. The members know that they form but a very small part of a very large profession, but they feel that they can and should help to the best of their ability.

The M. & M. Society, realizing that the questions are very broad, affecting thousands of the citizens of the United States, understood thoroughly the futility of any organization, large or small, attempting to formulate a new code that would be acceptable to the majority of the people interested in the business. Joining with other organizations whose combined membership was several thousand, and without doubt fairly representative, it urged to the utmost the appointment of a commission, competent to take all evidence that could possibly be submitted, and competent to advise Congress what, if any, alterations should be made.

Whether the commission idea is right or wrong, it was supported by every mining organization in the country that ventured an opinion on mining law, but Congress denied the request and failing to realize the complexity and breadth of the subject advised the mining men to bring to them specific changes upon which all mining men could agree, and if these changes seemed good they would be enacted into law.

It was with this idea in view that the council of the

M. & M. Society said: "Let us see if we can find out what mining men think in regard to a number of questions, let us try to find out upon what points, if any, they are in accord. If there are any, perhaps we can get these enacted into law, if we cannot get the whole subject reviewed as we desire."

If the whole scheme had been the idea of "a dozen clever and interesting gentlemen," "whose opinions might be anticipated by a detached observer," the questions would not have been referred to 14 other organizations with membership of several thousand, nor would the answers have been published so fully, divergent as many of them are.

Mr. Editor, it is up to you to help us find out how many think that all the damage is done that can be done, to find out whether anything can be done to help the prospector and operator and not try to belittle a serious endeavor by ridicule.

Tinkering With the Mining Law

The Editor:

Sir—I have read several contributions during the past year or two in your journal on the subject of a proposed revision of the mining law. I am one of those that are opposed to very much 'tinkering' with the old laws with which we are all familiar, but there is one phase of the existing law that has long been the source of discord, and which in my opinion could be amended to advantage. I refer to that part of the Federal law which requires an actual discovery prior to the location of a mining claim. Section 2320 of the Federal Revised Statutes declares that "no location of a mining claim shall be made until the discovery of a vein or lode within the limits of the claim located." This certainly is clear—no location can be legally made until the locator has an actual discovery of "mineral-bearing rock in place."

What is meant by "mineral-bearing rock in place"? It has been interpreted by the Department of the Interior and the courts to mean such a showing of mineral as would warrant a man of ordinary prudence in expending his time and labor upon the claim in the reasonable hope and expectation of developing a paying mine thereon, or, as expressed in a recent decision, "there must be actually physically exposed within the limits of the claim a vein or lode of mineral-bearing rock in place, possess-

ing in and of itself a present or prospective value for mining purposes."

Here we have both the language of the Federal Statute and its interpretation by the Department of the Interior and the courts. It is difficult to get away from the meaning of the statute, and it has been in the past the cause of much unnecessary trouble, to the extent of 'gun-plays' and even of killing.

It is not always possible to make a discovery without doing work—in some instances a great deal of work. For example, take that part of the Leadville district lying just south of the southern slope of Carbonate hill, where are some of the most valuable mines in the region—the Wolfstone, Maid of Erin, Henrietta, Adams, Morning Star, Evening Star, Catalpa, and numerous others—not one of which has an outcrop of ore, nor does any ore occur in any of these claims within several hundred feet of the surface. Here, of course, was an instance wherein the expenditure of thousands of dollars was necessary before a discovery, such as the Federal law plainly requires, could be made.

True, there is but one Leadville, but there are other districts where the geological conditions are essentially similar, if not identical. There are scores of mining claims in the Black Hills of South Dakota, where there is no outcrop, and in some instances the area under which lies a great amount of profitable ore covers many hundreds of acres, and no outcrop is to be seen. The formation—limestone, sandstone, quartzite, and shale, is nearly flat, as at Leadville, and the ore-horizons sometimes lie several hundred feet below the surface. In other parts of the West where ore occurs in sedimentary formations, conditions similar to those above described are known to exist to an extent that makes them common. In California valuable gold-bearing veins and gold-bearing gravels in places are covered by hundreds of feet of andesitic lava, through which the miner must sink a shaft, before he can make a discovery. Since the conditions above described are not uncommon, would it not be well to recognize the fact and to amend the mining law so that a prospector may legally locate a claim where no ore outcrops, but where, in his judgment, he will find ore if the necessary work be done, not leaving the matter to the uncertainty of a decision by the courts, always a process involving much time and an expense beyond the means of the prospector?

A great deal has been said about the pernicious effect of the extra-lateral right. True, it is responsible for perhaps 90% of all mining litigation in the United States, but we now have a wagon-load or so of 'judicial legislation' on this subject, so that we know about 'where we are at' and it seems needless to change it at this late day, for it would result in a confusion far worse than that which naturally flows from the operation of this law as it stands. It may be that a few more new mining districts will be discovered in the Western States, but, unfortunately they are not likely to be many. It is more probable that future discoveries will be made in old districts and probably in such parts of these districts as

have not yet attracted much attention by the richness of their ores, or because of the obscurity of mineralization or the absence of outcrop. Rochester, in Nevada, is a good example of the possibilities of the future in this direction, should the law of the extra-lateral right be repealed. Here was an old district, long idle, from which nearly every one had departed. The unexpected discovery of shipping ore in an old claim attracted immediate attention to the locality. A stampede ensued, and hundreds of new locations were made, blanketing the region for miles in every direction from Nenzel hill. In such a district, the effect of a law confining mining rights to vertical planes, as determined by the boundaries of the claims where there were old legally subsisting claims entitled to operate under the present law and many recent ones to work under such a new law as has been proposed, would simply result in chaos.

Let us not attempt to change the law so far as it relates to extra-lateral right, but see if something cannot be done to remove the difficulties of *bona-fide* location where no outcrop appears.

J. T. WILKINS.

Tonopah, Nevada, December 21.

Grinding-Mills at the Inspiration

The Editor:

Sir—I have read with interest your article on flotation, in the issue of October 28, with comment by Mr. Cole, and Mr. Cole's article of December 9 on the subject of grinding-mills at the Inspiration, and I naturally ask if Mr. Cole's articles are given without prejudice?

He states that the merits of the Hardinge and Marcy mills will be brought out in a test that is to be carried on by the Inspiration and Miami companies; that at Miami they are installing real Hardinge ball-mills arranged in a different manner than the Marcy arrangement at Inspiration, and yet he states that these results will be "conclusive." Does Mr. Cole think that the mining and milling fraternity will accept results as "conclusive" from him or anyone else in which the mills are operated in two separate plants, and while the ores are similar, yet their copper contents are entirely different, where orebodies vary from day to day as to their hardness, where the Hardinge mills are crushing the ore in two stages while the Marcy is doing it in one? Does Mr. Cole think that this "information will add materially to our knowledge of crushing"?

The pebble-mill has not yet been abandoned as far as I know, and it would be interesting if the Inspiration company or Mr. Cole would publish the long series of experiments and results that were carried on by the Inspiration company between Hardinge mills and a tube-mill. As Mr. Cole explains in the Transactions of the Institute, there were four different sizes of conical mills in the original test-plant and there was one tube-mill. We are sure that the manufacturers of this tube-mill,

the Chalmers & Williams Co., would be glad to have these results published.

My understanding is that the two conical mills that are now being placed at Inspiration were put in under a representation by the Hardinge company to do an equal amount of work as the present Marcy mills with very much less horse-power, namely, 300 hp. as compared with 450 hp., which is required for two Marcy mills. One thing the mining public is particularly interested in, is the amount in dollars and cents the Inspiration lost or gained by installing Marcy mills, and we hope Mr. Cole will give us this information.

Mr. Cole states Mr. Blickensderfer's article is unfair, on the comparative tests of the Marathon, Chilean, and Hardinge mills, because balls were not used in the Hardinge mills. This gentleman would not be unfair in making any comparison he chooses as long as he states the facts. I cannot see that it is unfair, particularly to one who is familiar with conditions. At the time the Marathon mill was installed by the Detroit Copper Co. in the summer of 1914, the standard equipment for crushing this character of ore in the Hardinge mill was flint pebbles, and that is what Mr. Cole was using also at this time at the Arizona Copper Co.'s plant. There was no available supply of cheap small iron balls that had been fully demonstrated a success that could be used in the Hardinge mill.

After all, the crushing problem is a matter of dollars and cents. Right here it is an interesting thing to know and to note that the success of re-grinding fine ores either in cone-mills or in cylindrical mills from a dollars and cents standpoint is due principally, not to Mr. Hardinge nor to Mr. Cole nor to the Miami Copper Co., but to the development of a cheap iron ball, called 'manganoid,' which is manufactured in a malleable iron foundry and extensively used by many, including the Miami and Anaconda companies. But could Mr. Blickensderfer have used iron balls without criticism from Mr. Cole, as they were not real Hardinge ball-mills? I am sure the mining public would like to know the exact difference between the real Hardinge ball-mills that are now being installed at Inspiration and the Hardinge mill equipped with 11 tons of steel balls that was used in competition with the Marcy mill during December 1914 at the Inspiration test-plant.

As to the work that is being done on crushing problems in the South-west, as mentioned by Mr. Cole, there are many other places where real experimental work has been conducted, but unfortunately results have not been published, as in the case of Inspiration. This refers particularly to the comparison at the Butte & Superior between a medium short tube-mill, a Hardinge mill, and a Chilean mill; to experiments conducted at the Alaska Treadwell between stamps and the conical mill; to experiments conducted at the Alaska Juneau, Alaska Gastineau, Britannia, and Braden mines. None of these results has been published, but many mill-men are familiar with the results and we all know the outcome of these experiments and the type of mill the respective companies adopted.

My conclusion is that the Blickensderfer article is a valuable contribution on the art of ore-grinding, as most practical men know the relative difference between ball and pebble mills in mesh-tons per horse-power; that the man who suggested the simplified crushing-system at Inspiration, or the men, or the company of men, contributed a most valuable idea to the mining public—an idea that has been copied extensively and successfully throughout the country—an idea that is highly valuable and most welcome to the small operator as well as the big producer.

The crushing of the ore is the one big expense in milling. What is required is exact facts, from which we can draw our own conclusions—conclusive or otherwise.

C. T. VAN WINKLE.

Salt Lake City, December 20.

The Prevention of Misfires

The Editor:

Sir—I have read with great interest the article in your issue of December 16, by Mr. E. F. Brooks, on this subject, which is one of great importance to California operators, for during last year 10 men were killed through misfires. This is approximately 25% of the total men killed from all causes, a record that compares very unfavorably with that of the average metal-mining State.

Mr. Brooks offers some excellent advice and touches on the following causes of misfires: poor judgment in placing drill-holes; the use of inferior caps and fuse; improper sequence in the 'spitting' of holes; 'spitting' too many holes by one man; the use of grease for waterproofing; and improper crimping of the cap.

There is omitted a cause of misfires that I believe to be of the utmost importance, namely, improper methods of making the primer. Any method of making the primer in which the fuse must be bent more than 35 or 40 degrees is likely to cause a misfire. Especially is this the case if the fuse is cold when the primer is made. The lacing method, and the method in which the capped fuse is placed in the end of the cartridge and the fuse bent backward (through 180 degrees) are most undesirable.

The U. S. Bureau of Mines, after extended experiments, made under varied conditions, found that there were two methods of making the primer that resulted in a minimum of misfires. These two methods, which are also recommended by manufacturers of dynamite, are as follows:

(a) Loosen the paper at the end of the cartridge, make a hole with a wooden punch, and insert the capped fuse. Then tie the paper about the fuse with a piece of string. In this method the fuse leads straight away from the cartridge, and thus is not bent.

(b) Make a diagonal hole in the side of the cartridge by means of a wooden punch. Place the capped fuse in the hole and tie the fuse to the cartridge near the top of the latter. The hole should be punched so that the fuse

will not be bent any more than is absolutely necessary.

It is usually claimed that it is impossible to compel miners to make primers properly. This object is being accomplished at many mines by the simple expedient of discharging the miner who makes the primer by any method other than the one he has been instructed to use.

If miners will follow the good advice given in Mr. Brooks's article, and will also make their primers properly, the number of deaths resulting from misfires must certainly be lessened.

EDWARD HIGGINS.

San Francisco, December 16.

The Editor:

Sir—In an article in your issue of December 16, 1916, E. F. Brooks argues against the use of tamping, stating that "even the air itself will offer sufficient resistance to the exploding dynamite to constitute good tamping." If such were the fact, bulldozing would be a most efficient operation.

The increase of the effect of good tamping is well known. From Technical Paper No. 17 of the U. S. Bureau of Mines publications, I extract the following: "The use of the most efficient stemming materials may increase the useful energy of the shot 93%, the use of the least efficient stemming materials may increase that energy 60%. Accordingly it is clear that the use of stemming is necessary when the maximum useful effect from an explosive is desired."

In the argument against tamping Mr. Brooks states that "the side-spitting of the fire in the fuse will sometimes set fire to the powder which, while it does not explode, will generate sufficient gas to force the tamping out of the hole, drawing the fuse with it." This statement indicates that the primer is placed at the bottom of the hole. In good practice today the primer is placed at the top of the charge. If it is so placed and the fuse is not laced through the powder, the fuse will not ignite the powder.

A cause of misfires often overlooked is the moisture in the fuse.

Berkeley, December 28.

W. S. WEEKS.

Regarding Foreign Capital

The Editor:

Sir—Just a word of protest against Mr. Nipper's remarks on this subject in your issue of December 2.

Mr. Nipper puts me in the false position of being opposed to foreign capital entering the mining field in China. In my letter on this subject, to which he refers, I laid particular emphasis on the desirability of inducing foreign capital to come to China, and I merely suggested in a tentative way that some form of limitation might be desirable, at least from the Chinese point of view. Let me spell it out for the benefit of the most casual reader: I am in favor of foreign capital to develop mining in China and of giving it the fair deal. I beg to differ with Mr. Nipper when he says that China has no

money to develop her mines. There is plenty of money in China, as anyone knows who is familiar with business conditions in the Orient. It needs only the stimulation afforded by a few successful mines and the encouragement of a good mining bureau to enlist this capital in mining. As for Mr. Nipper's concluding remarks, pointing out that there is loss as well as gain in mining, there is nothing very novel in that: we have learned that to our sorrow, even in China.

Los Angeles, December 9.

M. B. YUNG.

Co-operative Trade Agreements

The Editor:

Sir—I enclose herewith Referendum No. 17 of the Chamber of Commerce of the United States, to be voted on on or before January 12, 1917.

You will observe that the subject of this referendum directly relates to the mining industry in that "the Committee recommends that there should be remedial legislation to permit co-operative agreements under Federal supervision in those industries which involve primary natural resources, on condition that the agreements in fact tend to conserve the resources, to lessen accidents, and to promote the public interest."

To conserve the mineral resources of the United States is a subject the importance of which can scarcely be over-estimated. It seems to me to be the most important economic subject we have before us, for if the United States is to grow as an industrial nation at the same rate that it has been growing in the past we must take care that the basic resources which govern industry are conserved to the fullest extent.

Before issuing this referendum our committee took the matter up with the Federal Trade Commission and with the American Federation of Labor. I cannot speak officially for the Federal Trade Commission, but I assure you that its members look favorably upon the general plan, provided the interest of the people is safeguarded in its execution. The American Federation of Labor has officially, through its highest officers, commended the proposition.

May we not have your editorial co-operation and support?

New York, December 21.

W. L. SAUNDERS.

The Great Calamity

The Editor:

Sir—I have cancelled my table reservation for New Year's Eve dinner at a great hotel because I have read your masterly arraignment of cold-blooded neutrality as published in your issue of December 23 under caption 'The Great Calamity.'

I thank you for preventing me from unwittingly making an ass of myself. These are not times for hilarity, but for stock-taking in the house of human relationships.

San Francisco, December 29.

PERCY WILLIAMS.

Financial Review of 1916

By Osmund Phillips, Editor of 'The Annalist'

As we begin another year it seems necessary to emphasize the fact that prosperity in the United States is not dependent upon the prolongation of the War. If we are to get out of this year's economic effort the fullest possible results for the country as a whole, business-men and bankers throughout the land should be impressed with the fact that the course which business will take will depend upon them and upon the people much more than upon the continuation of the struggle in Europe.

An eminent banker has recently been saying to his friends that the United States had already gotten out of the War all the prosperity which it was safe for us to extract from that particular source. It is not safe, certainly it is not desirable, to go on indefinitely serving the purposes of war to the necessary neglect of much in the way of peaceful demands and peaceful opportunity.

It is true that war has helped to enrich the United States. Also it is true that war has helped to impoverish Europe, which is a fact despite the surface prosperity that has attended the waging of the War in all of the great industrial countries engaged in it. Prices are high, labor was never so fully employed so far as it is available, and never were profits so rapidly attained. But in Europe these are all subject to existing and future taxation that the cost of the War makes inevitable. Directly we escape most taxation of that sort, but indirectly we could not escape the consequences of devoting a large and possibly an increasingly large share of our natural resources to the development of a war trade one of whose chief effects has been to throw our export trade out of all natural relation to our import trade.

That has brought in the flood of gold which has done so much to facilitate the financing of the unheard of volume of business thrust upon the country, and it has also brought back to us, by the billions, American securities formerly owned abroad. They were the outward evidence of America's indebtedness to Europe for capital invested here in developing transportation, in promoting industry, and in enlarging our power to trade. There is no hardship, but actual benefit, in being able to cancel this indebtedness and to become ourselves the owners of that portion of our industrial establishment which was formerly owned abroad. Besides the gold that we have received and the securities that we have taken back, we have also lent to the rest of the world on what for us was a very large scale. That, too, was well worth doing. It helped greatly in stimulating our trade and in supporting it, but there is a limit to the amount which could be judiciously invested in that way taking all the facts of the case into consideration.

An indefinite prolongation of the War would further

dislocate the ordinary operations of industry and would eventually lead to our selling abroad more than our foreign customers could afford to buy. The test of that would not rest solely in their ability to pay the interest and the principal of the debt which they might contract with us. We have to consider their future, for as customers in the future as they have been in the past it is highly important to us that they should remain not only solvent but capable of buying goods beyond their bare necessities. The danger in our importing too much gold does not lay solely in our getting more than we could usefully employ in our own banking system. The danger lies in part in the countries of Europe draining themselves of gold to an extent that will weaken them so much that their recovery after the cessation of the War will be slower and much more difficult.

Coming back to our own industrial situation, it is clear that it would be particularly undesirable to increase further and further the capacity of plants devoted exclusively to the production of war goods and incapable of efficient production of goods of other sort once the War demand came to an end. That is not true, of course, of steel mills whose output is as available for the comfortable purposes of peace as they are for the stern purposes of war. A blast-furnace or a rolling-mill is by no means in the same category with the powder-plant or the gun-factory.

It is thus true that business might suffer greatly from a protracted prolongation of the War just as surely as it has benefited greatly, in the immediate sense, from the demands which the War brought into existence. It follows that the ending of the War is not a thing to be feared in the material sense. We have but to look a little bit ahead and to think of the morrow as equally important in the life of a nation as is today, to realize that the real material as, certainly, the moral interests of the United States will best be served by as early an ending of the war in Europe as is consistent with the attainment of a lasting peace.

I have dwelt at some length on this phase of the matter, for it seems important to combat the thought that prosperity in the United States is synonymous with the destruction of life and property in Europe. The loss of prosperity here would be surely a small price to pay for the return of world peace, but the fact of the matter is that that need not be part of the price. Many readjustments will be called for, but with intelligent planning those readjustments can be foreseen and met without undue disturbance. That is truer as matters stand now, or as matters will stand three or six months hence, than it would be were the War to last a year or two years more. The problems of readjustment will increase

in proportion to the inroads which the War will make upon the highest form of any country's capital—labor—and upon the natural resources of the world.

Looking back, what we find in the financial and business record of the past year is activity in a degree which would have been thought impossible before it was attained. Our foreign trade has reached a total falling in the aggregate only a little short of \$8,000,000,000, while a total in the neighborhood of \$5,000,000,000 the year before seemed an almost impossible accomplishment. Side by side with our foreign trade has grown our domestic trade, which, aside from all business directly due to the War—not to be regarded as exceeding the total amount of our exports—reached a volume never before nearly approached. If we did \$8,000,000,000 of foreign trade, as foreign trade is usually spoken of, exports and imports together, we have probably done five or six times that much trade at home.

From both of these—trade at home and trade abroad—we have derived enormous profits. Evidence of that is seen in the increased dividends which American corporations declared and in the more secure financial position which so many of our business concerns have attained. The profits have been so large that few have felt like disbursing more than a fraction of them. It is one of the reassuring phases of the present time that the managements of most of our corporations have not proceeded on the theory that profits such as we have had this past year are to be expected indefinitely. The fact is that such profits are not needed to maintain a steady flow of prosperity. Excessive profits are of their very nature out of the ordinary, and imply conditions which cannot last. This has been recognized by nearly all business men even though individuals may have been more extravagant than has been wise. That, however, is inevitable, for no one puts up with bare necessities when something of luxury is within reach. Nor is what I am now saying a contradiction of the assertion that prosperity will outlast the War. I have in mind a normal prosperity probably on a lower scale of prices, but none the less effective in providing the wants of the people and in enabling them to enjoy the good things of life. Prosperity of that sort is better assured of so much of permanency as can attach to the fluctuating fortunes of human endeavor.

Things have already come about that will tend to lessen the extent of Europe's war purchases in the United States, even should the fighting, as still seems probable, continue for months to come. The Allied countries have been striving strenuously to render themselves so far as possible independent of other countries in providing munitions of war, and it has been pointed out semi-officially, as well as privately, that it was not to be expected that the Allies would place many more munition orders in this country. That is one thing which is working in the direction of cutting down our exports of purely war material. There are other forces working in the same direction.

If the countries of Europe could borrow here without

limit they would no doubt buy many things which they will not buy if they find it difficult to provide the necessary money, and it is no longer as easy to get money as it was. Europe's holdings of our securities, particularly England's holdings of those securities, are still far from being exhausted, but the end of those resources is in sight. Of gold Europe still has a vast amount, but in international exchange gold is worth but its bullion value, and after all that does not go very far. If the gold which we received from abroad is not to be made the basis of credit to be granted to foreign customers as freely as we would grant it to our own customers, it follows necessarily that our foreign customers will have to buy less than they might like.

Real difficulty has been placed in the way of foreign financing in this country by the statement recently issued by the Federal Reserve Board, and, while further foreign loans are to be expected, it is most likely that they will be fewer in number and smaller in the aggregate than they would have been had no such check been put upon international banking operations. The matters which led up to the Federal Reserve Board's warning against the proposed issue of British and French Treasury bills was not handled as it should have been. The Board was placed in a position in which it felt compelled to make a public statement of the sort which it did make, and though that was in some respects unfortunately worded it seems likely that the final effect will be a good one. We should not extend foreign credits except to such borrowers and under such conditions as can stand the closest scrutiny. Presumably the countries in the best credit will find a means of providing for their essential credit requirements in this market and any credits beyond the least which are needed for the safeguarding of our own trade would carry us into speculative fields which it is not desirable that we should enter.

England and her allies are in a position to give us the best of security for hundreds of millions more in loans and are able besides to provide us with hundreds of millions of gold beyond what they have already sent. Between the two they are not likely to want means of paying for the goods which they most need. At the same time a restriction has been placed upon unlimited exports and the result of that should be good rather than bad.

The business and financial position of the United States is more intimately related with international affairs now than it has ever been in the past. That from one point of view increases the intricacies of trade and finance, but it is predicated on facts which have given us possession of strength greater than this country ever had before. The re-purchase of our own securities from abroad and the loans which we have made to others have converted the United States from a debtor into a creditor nation. From now on we shall draw interest from abroad instead of annually paying a large sum on the stocks and bonds of American corporations owned in other countries. But that is only one direction in

which the position of the United States has been and is being strengthened. The great impetus given to American shipbuilding by the scarcity caused by the War will in due course put this nation in a more independent position in respect to the trade-routes between America and foreign ports than it has occupied in many decades. The importance of this will be all the greater in view of the efforts which the exporting countries of Europe are likely to make to regain the trade that they have lost during the War. We shall after a while no longer be beholden to England or to Germany or to some other country for the ships which carry American goods to foreign ports or which bring to our own ports the raw materials produced elsewhere and needed here.

Moreover our industries have been relieved in part at least of their dependence upon foreign sources of supplies. That is the movement which should be carried much further and should be continued not only for the space of the War but beyond that time until we are making the most effective use possible of the materials which we have at hand. We have been a wasteful nation, but it is high time that we should accept the fact that our resources are not inexhaustible, nearly as they would come to being that if we used them as we should.

Much has been done to make the country great industrially and commercially, but a great deal remains that could be done which would greatly strengthen the country by increasing its productive capacity by rendering itself more efficient than it has yet become. If employers of labor foresee that the demand for their product is likely to be reduced by the coming of peace they should see how they can employ that labor in some other direction, or if that be impossible they should work with others to provide the employment which would be needed for those idle hands. This would be some of the most useful work which the manufacturers and merchants of this country could possibly do. There will be plenty of opportunity to employ profitably all the labor which may be released as a result of the ending of the War, but immediate work for that labor cannot be found unless plans are thought out in advance.

Fortunately, there is no doubt of the country's ability to provide the banking facilities needed for any effort which is to be made either at home or in foreign trade. Thanks to the creation of the Federal Reserve Banking system and thanks, too, to the support which bank reserves have received from the great inflow of gold, it will be possible to do things easily which would have been all but impossible under the older and less elastic scheme of banking. But only a beginning has yet been made in the direction of banking development along the lines provided in the Federal Reserve Act. Bankers should look forward to the time when all the banking institutions of the country will be united in a single system, each unit lending to the other the aid of its co-operation. Already a great deal more confidence is felt in the soundness of our banking position than was felt before the enactment of the Federal Reserve Act. Still more confidence would be felt were the facilities of that

system availed of by all eligible institutions instead of being confined as it practically is now to the National banks. The Federal Reserve system has done two things: among others, it has made funds for commercial purposes cheaper than they were and also it has made the supply of these funds much more responsive to the trade needs of the country. The latter is the more important of the two. It is now unlikely that a check will be put upon worth-while trade merely from fear that the money with which to do it will be lacking. It makes relatively little difference whether a merchant has to pay 4 or 5% for his money; it makes a vast deal of difference if he can get money freely or cannot get money at all.

During the past year we have witnessed one or two flurries in the money market, but practically they have been confined to the Wall Street money market and even more narrowly to the Stock Exchange money market. A 15% rate there is of much less consequence to the country than would be a comparable rate for commercial paper. That is because speculation in securities is of no importance whatever in contrast with the conduct of trade. If speculators have to pay dear for the money which they use, few but themselves suffer. The same may be said of the losses which speculators undergo when, as happened this very month, the market structure which they have reared is suddenly subjected to greater pressure than it can bear. Speculating in stocks on margin may do speculators a lot of good if they are fortunate enough to take their profits in time, but the country at large gets very little good out of it. That is one reason why no great concern need be felt over the fact that stocks have fallen a good deal below the prices which obtained during the year. The properties which they represent were as valuable on December 21 when prices on the Stock Exchange were declining violently as they had been worth a month or two before when prices were rising rapidly. Without regard to the course which the stock market has followed the fact is that real values have increased during the year that has just ended. Corporations have earned much more in many instances than they ever earned before and the position of the holders of their securities is better therefor. It is certainly not to the investor's advantage to have stocks carried to high prices, possibly to prices beyond their actual worth, and it is not he who really suffers when prices built up on speculation yield to the inevitable.

Industry and trade looking backward find an extraordinary record of achievement during the past year, and looking forward they see many opportunities which will insure the continuance of at least as much prosperity as the country needs if the opportunities are intelligently availed of. Business men should lend their aid to every efficient effort which may be made to make sure that whenever the War may end and whatever changes the year may bring, new work may be found for every hand that may become idle. In a country of resources as great as ours still only partly developed, there can be no good reason why any willing hand should be idle, and without idleness there can be no real lack of prosperity.

Tungsten Manufacture in England

*Although the British Empire contains some of the most important sources of tungsten ore, before the War it depended mainly on Germany for the metallic tungsten needed for the manufacture of high-speed steel, and when hostilities began only enough for three months was on hand. Under these circumstances vigorous measures were required to remedy the deficiency, and in a few weeks a company, High Speed Steel Alloys (Limited), was formed for the purpose. Arthur Balfour, of the Dannemora Steel Works at Sheffield, who took a leading part in its establishment, was chosen chairman, and A. J. Hobson, of Messrs. William Jessop & Sons, vice-chairman, while the capital was subscribed by some 30 steel-making firms, mostly belonging to Sheffield, and collectively producing from 70 to 80% of the high-speed steel made in this country before the War. The company, of which Julius L. F. Vogel is manager, started building operations on a site of about six acres at Widnes in Lancashire at the end of 1914, and by the following July the factory was producing tungsten powder. Work has since been carried on continuously day and night, though the output, which has reached three tons daily, has occasionally been reduced through lack of the necessary supplies of ore. There is no secret in the process of manufacture. In the first department of the factory the wolfram ore is crushed, screened, and mixed with soda ash. Here a magnetic separator, for separating the wolfram from the tin ore which it contains, is temporarily installed, but an entirely new building for the grinding, roasting, and magnetic separation of mixed ores is now being erected. In the second department the mixture of ore and soda is roasted in reverberatory-furnaces, and then the product is taken to the third department, where it is broken up. The next process consists in boiling it with water, when the tungsten is obtained in the form of a solution of tungstate of soda, which is freed from solid impurities by filtration, and then, in the fifth department, treated with hydrochloric acid. The result is to deposit tungstic acid, which is obtained as a thick yellow paste. This, after being dried and powdered, is packed into crucibles with powdered anthracite, and the next step is to reduce the oxide to metal by heating the crucibles. At present coke furnaces are employed for this purpose, but a continuous furnace 130 ft. long, and fired with producer gas made by two Wilson producers using bituminous coal is being erected and is expected, by replacing the coke furnaces, to reduce costs considerably. Finally, the metal from the crucibles is washed and dried and packed in tin-lined wooden cases for delivery to the steel makers. The tungsten produced has had an average purity of 98½%, or 1% more than that previously obtained from Germany, and a substantial proportion has averaged over 99%. This purity is of marked advantage to makers of high-speed steel, since it reduces the wear

and tear on crucibles, preventing the loss of steel through damaged crucibles, and promotes the yield of sound ingots, which can be hammered and rolled into finished bars of uniform high grade with a minimum of waste and defective material. But to maintain it continual care is required, and daily assays are carried out of all raw materials and intermediate and finished products in a laboratory in which there is also a staff of chemists engaged on research work for improving the methods.

The Tungsten Situation

*While the present price of tungsten at \$20 per unit permits of the profitable mining of the mineral particularly in the medium and high-grade properties, current quotations hardly seem in accord with the existing situation as regards supply and demand. Users of tungsten are not over-stocked, but on the contrary, are likely to experience considerable difficulty in filling their requirements. It is an open secret that the large steel manufacturers have formed a combine to keep down the price of the metal; but as their needs grow more urgent, and when they are brought into competition with foreign bidders, it would seem as if quotations on tungsten must record a material advance, regardless of bearish manipulations. Knowing that the demand equals and probably exceeds the present output, tungsten producers should be able to form some sort of protective organization of their own, and refuse to part with their production except at a fixed and reasonable price. The foreign situation for tungsten is extremely bullish. In Great Britain alone plants now in operation for the production of tungsten concentrate cannot obtain a sufficient supply of ore to keep running at anywhere near capacity. Such an authority as Admiral Slade is quoted as expressing the belief that there are now in Great Britain sufficient plants to deal with more than twice the amount of ore that can be procured or is ever likely to be procurable. There also are important works in France that will consume a good deal of the metal. In the United States the Primos Chemical Co. has within the past year considerably enlarged its capacity, and the Chemical Products Co. has recently completed a new large reduction plant near Washington, D. C., designed particularly for the treatment of lower-grade concentrate. The steel interests generally, carrying heavier bookings than ever before, are absorbing their due quota of the mineral. There is another factor in the situation not to be overlooked or under-rated, and this is the projected great enlargement of the United States navy, whose great steel battleships, as well as the minor vessels, will call for a big supply of tungsten. At the annual meeting of the Colorado Metal Mining Association, to be held at Denver in January, the tungsten situation will be one of the most conspicuous subjects brought up for attention; and it is to be hoped some line of procedure will be evolved adequately to protect the producers and stabilize prices at more suitable levels.

*Abstract from *Daily Mining Record*.

Flotation in 1916

By An Occasional Correspondent

No one could have predicted three years ago that the flotation process would have expanded so rapidly in this short period that the quantity of ore to be treated daily—in the world—would amount to 150,000 tons. It is a reasonable expectation that this tonnage will be doubled in another three years. The mills of the gods are beginning to grind not only "exceeding small" but exceedingly fast.

Exchange of technical information has contributed largely to this result. Metallurgists have learned that it is difficult to keep secrets—so why have secrets? If you appear anxious to tell your professional brother something that will help him, the psychological effect is to make him want to tell you all that he can to help you in return. The result is improved practice for both. Time was when the operations in metallurgical plants were carefully guarded, and supposedly valuable processes were directed by supposedly wise men. In almost every case these secret plants were found to be harboring secrets, not of technical success, but of failure. Many of these plants were losing too much in tailing, in slag, or in flue-dust, or in some other less accountable way. Some of them were superintended by men who were aware of their own shortcomings and who knew they were not doing good work. The companies for whom they worked had little ore to treat, or a very low-grade ore, and did not wish the investing public to be told the truth. Manipulation of stock-markets is more easily accomplished if the metallurgical operations of a company are conducted in secret. Sometimes there are sinister reasons for secrecy, as the mining fraternity knows full well. Suspicion is aroused when a plant is operated behind closed doors, and while the layman may be impressed by the high fences and the numerous watchmen, the very fact of secrecy generally suggests incompetence or dishonesty to those who are versed in technology. For this reason the attempts a few years ago to stifle the publication of technical information concerning the flotation process met with decided resistance from members of the profession. Whether rightly or wrongly, the impression became general that the Minerals Separation people were enforcing a clause in their contracts with those that dealt with them, requiring such to withhold all information on experimentation and demanding that they destroy the experimental machines used in testing the ores. It was given out that the M. S. company did not want information on the process to come from any one but the accredited engineers of the company. Also they expected such high royalty for the use of their process that it was virtually a hold-up. This was the impression that obtained and whether it was correct or not is not the immediate question. In reaction against

this impression the independent metallurgist told all he could learn about the process. The sudden flood of literature that appeared in the technical press surpassed anything that had ever been done in making clear the exact workings of a metallurgical process and no one who can read need lack information.

The process had been laughed at for years by American metallurgists, then mildly tolerated, and then allowed a restricted field of application, but it was not taken up with enthusiasm for the reason that nearly every engineer who tested it in a laboratory ran into difficulties that he could not understand, and he gave it up. It was the general impression that the process was too delicate and too restricted in its application. It is to the great credit of the Minerals Separation people that they early saw the tremendous importance of this process in case it could be made to solve the slime problem in milling. Since they had expended a fortune in bringing the process to a commercially practicable stage, it was natural that they should expect a high return for the use of it, and further, that they should desire that all the technical information given to those using the process should come from their office. It was not surprising that they should endeavor to keep the application of the process in such a state that they would possess more technical information than anyone else, so that infringers could not hope to have the same success as the licensees.

This is all easy to understand and many sympathize with them in their wish to develop their process along such lines, for the amount of money that they had expended in reaching the point they had achieved was considerable. Unfortunately much of this money had been spent in litigation in the British and Australian courts and there was still a question as to just what rights they did own. So, when a rather high royalty was asked for the use of their process, there were those in America who felt that the question of ownership of patent rights was too much in doubt for them to pay the tax. When the total cost of milling in such a region as south-eastern Missouri is about 25c. per ton, and the total cost in Utah is not much more, operators naturally balked at the payment of a 25c. royalty on every ton of ore. This reluctance on their part was further aggravated by the understanding that the Minerals Separation Co. insisted on applying the royalty to every ton of ore entering a mill, whether or not the ore was all treated by flotation. This was due to the idea of the M. S. people that their process could be applied to the total mill-feed without the use of many auxiliary machines, thereby simplifying the flow-sheet as well as bringing a greater return into the coffers of the company. In consequence, the profession

began to feel that the Minerals Separation Co. was too greedy, and it now seems that the company made a great mistake by allowing this impression to get about. The royalty now asked is not 25c. per ton—in most cases it is considerably less.

None of us wants to see any set of men lose money after developing to a stage of commercial success so useful a process as the one in question. But if the impression prevails that a company is trying to claim everything in sight in the flotation field; that it is not looking for sympathy; that it is going to insist on its legal rights, as given to it by the United States patent laws; that it is going to charge all the royalty that the traffic will bear, and that it is going to give no more technical information than is necessary for the profitable operations of its own clients, then that company makes a great mistake in policy. That impression still prevails, and has resulted in the flood of literature on the subject. Engineers have tried to make sure that everyone should so thoroughly understand the process that none should be at the mercy of anybody.

The rapid application of flotation came with the realization that it was a process adapted to the treatment of slime, and also that it had been developed to a stage where it was not such a delicate operation as had at first been supposed. The chances of losing money by the installation of a process that might fail were lessened. The world was in need of it, because the magnitude of milling operations, with attendant losses, had become enormous. Then the War created an unprecedented market for metals and sent prices to such figures that the utilization of any process that promised success was hastened. Costly mistakes could be corrected and the losses promptly stopped. A vast amount of investigation has been done in adapting flotation to the treatment of various ores. There were hundreds who set up laboratory machines and used them in testing their own ores. Every old mine-dump, or mill-dump, or accumulation of tailing in the bend of some stream, or deposit of low-grade or of complex ore, is being tested to see whether flotation will make it a source of money. The application of the various flotation processes is being extended to ever wider fields. Oxidized ores of lead and of copper, ores of gold and of silver, scheelite, the Sudbury copper-nickel ores, and even anthracite culm, is being tested by flotation, and a first failure in test work is no longer considered as final evidence of the inadaptability of the process. Confidence is felt that ultimately some method of treating all of these materials, and others, will be devised. The time soon will come when even the 'pay ore' that is now going to the furnace will be investigated with a view to ascertaining its amenability to flotation and by fine-grinding converted into a more concentrated material of a self-fluxing composition. Wherever an expensive operation is being carried on, or a high freight-rate is being paid, an effort will be made to obtain a higher concentration of the material in order to reduce the cost. In other words, the flotation process is proving to be not only an instrument for the conservation of our

national resources by making a higher recovery possible, but it has cheapened processes and developed new resources by treating ores that were formerly too complex for concentration by other methods. The past year has seen much of this, and the coming years will witness many other innovations in metallurgical methods.

At first the treatment of flotation-concentrate by smelters seemed to be a serious problem, and it is still a difficulty. Some of the lead smelters have considered raising the roasting cost on this material. The copper smelters have found that they can handle flotation concentrate fairly well in the reverberatory furnace, but the zinc smelters have not been able to prevent the unusually large dust-losses during roasting. At the beginning of 1917 the opinion is forming that the fineness of division of the flotation-concentrate will be turned to advantage in new methods of metallurgy soon to be developed. At Clifton, Arizona, an investigation is now under way to find a method of leaching raw copper-sulphide flotation-concentrate without drying. The finely ground material is in ideal condition for a hydro-metallurgical process. The possibilities of using this new method effectively are only beginning to be appreciated. Flotation was first used to stop losses, then applied to ores that formerly could not be treated, then to the cheapening of former processes, and soon it is going to overthrow the former standard metallurgical processes and develop methods of ore treatment that will in some instances result in the direct production of metal at the mine. This last is greatly to be desired in a country where great distances and high freight-rates permit the transportation of only the most highly concentrated products.

Great ingenuity is evident in the development of oil-feeders and there are now devices available that will feed oil for either the largest or the smallest mill at a uniform rate and without danger of clogging or otherwise going wrong. The mechanical handling of flotation-froth after it has been made has also received much attention. It has been found that tough froth is easily broken by a spray of water traveling at a high velocity. A solid stream of water is far less effective. After breaking, the thickening of the pulp for proper filtering is important, as a wet flotation-concentrate causes endless trouble both in shipping and smelting. The froth is never completely broken down and as a result it occasionally collects on the thickeners to depths of several feet and special arrangements have to be provided for prevention of loss in the overflow. The vacuum-type of filters, especially those that operate continuously, have received almost universal acceptance.

A better understanding of the process has resulted from the many theoretical papers published during the past year. The two principal theories are those depending on surface-tension phenomena and those which are more frankly 'colloidal.' Bancroft has stated that we have here a special case of oil-emulsions in which water is the dispersive phase and the oil is trying to be the continuous phase, although used in such small amounts as

to be almost lost in the ore-pulp. The whole subject is in need of revision by somebody who understands all the theories that have so far been advanced. The ordinary metallurgist is at sea in the midst of the many new terms

other, but their work requires to be harmonized and edited by some one not interested in upholding any particular theory. Already a number of engineers who have read these papers with attention have been able to

SIMPLE TUBE-GRATE CELL AT THE ARIZONA COPPER CO.'S MILL, MORENCI, ARIZONA.

DETAILS OF FLOTATION-CELL AT THE CALAVERAS COPPER CO., CALIFORNIA.

used by the conflicting theorizers. Actually there is little room for conflict, as most of the parties to the arguments have a few truths that they are trying to make universal. Most of them are right in one way or an-

other, but their work requires to be harmonized and have made experimental observations which support the various theoretical points advanced. Flotation has been admitted to be a rather delicate process and difficulties

unexpected and puzzling often develop that are inexplicable.

With the further development of rational theories these difficulties will be better understood and finally overcome. At the present time many of the disturbing substances have been identified and the usual course now pursued is one of prevention—keeping out the substances or factors which cause the trouble. The next step will be to find a corrective measure that will successfully treat by flotation a lot of ore that has been spoiled by the entrance of some disturbing factor.

By the beginning of 1916 the development of the flotation process had been such that it was possible to estimate the probable tonnage to be treated by the end of the year. No embarrassment ensued like that due to the scarcity of suitable oils in 1915. Oils still cost money but the oil companies have been accelerating their production and presenting other products for flotation use in addition to those previously in demand.

At the present time the tonnage of ore being floated is approaching 50,000,000 tons per annum and it is certain that it will pass that mark during the coming year. Of course, not all of this is in the United States. The tonnage in the United States is difficult to estimate on account of the litigation, but it is thought that about 30,000,000 tons annually is a rather low estimate. Anaconda and Inspiration alone are milling together about 11,000,000 tons of ore that goes through flotation-machines.

Referring to the oils again, it is little matter of wonder that there should be some difficulty in obtaining pine-oil and other valuable products after the sudden expansion of flotation in the past three years. The War threw an additional burden on the turpentine and pine-oil producers, and the result was that prices soared. Coal-tar and coal-creosote became popular and during the past year there has been some difficulty in obtaining supplies of them at reasonable prices. For once it has been the buyer who has had to get down on his knees and beg. This situation is already being relieved by the further use of tars east of the Rocky Mountains. All of the coal-gas plants in the inter-mountain region can now market their tar and creosote, whereas three years ago it was a drug on their hands. With the finding of local uses for ammonia and gas it is believed that the use of by-product coking-plants in the West is nearly at hand. All of the coke made in the inter-mountain region is now beehive-oven coke and the by-products are wasted. Already there seems to be a chance to combine ammonia with the phosphoric acid from some of the phosphate deposits to make a double fertilizer which will be in a form concentrated enough to stand shipment to the points of consumption. The metallurgical use of the gas from by-product coking-plants is not difficult. In other words, the probable effect of the sudden expansion of the flotation process will be to make possible the building of by-product coking-plants in the inter-mountain and Pacific Coast regions.

The year has seen great development in the use of

other oils than the coal-distillation products. The destructive distillation products of pine, cedar, fir, hardwoods, and sage-brush have gained in favor. While the idea of sage-brush oil at first seemed laughable, it does not seem to be an impossibility. It would appear that a 4% yield of sage-tar is practicable and that it is the full equivalent—if not the superior—of pine-oil for many purposes. If it can be sold in the West for 50 cents per gallon, it will become a serious competitor of pine-oil at 40c. in the East. It is possible that the cost of production of sage-brush oil will be as low as 50c. per gal. in a crude plant and there is no knowing how much cheaper it might be made by proper organization and engineering.

The commonly accepted division of flotation-oils into 'frothers' and 'collectors' has met general acceptance and at the present time the coal-products are being used as 'collectors,' together with other non-frothing oils, such as crude petroleum or various petroleum-distillation products. For 'frothers' the pine-oils, soft and hardwood creosotes, and coal-creosote are now being largely used. Sage-brush oil is classed as a good 'frother.'

Much has been done during the past year in developing mechanical appliances for flotation. The reports on the work at Inspiration, at Morenci, at Anaconda, and other places, have shown widely different equipments. At Anaconda the standard type of Minerals Separation machine has been at work. It has shown that it consumes more power than a pneumatic machine if the oil is added to the tube-mills before final grinding of the ore. However, at Anaconda the oil used is an acid-sludge and must be added to the flotation-machines. This puts the burden of emulsification on the flotation-machine and would make a pneumatic equipment as expensive to operate as the Minerals Separation machines at Anaconda.

Much has been heard recently of 'sub-aeration' machines, the air being added beneath the paddles of a 'mechanically agitated' flotation-machine. This is said to result in a saving of power and of flotation-oil, and occasionally it gives a better recovery of the mineral being concentrated. The Minerals Separation company and its engineers seem to own most of the sub-aeration patents and this machine seems to be an answer to the pneumatic machines that have been developed out of their hands.

Pneumatic machines of all shapes and sizes have appeared in practice during the past year. Many of them are close imitations of Callow's original device. The Inspiration machine is notable for its simplicity. It is the development of a launder with a porous bottom for admitting air. At the present time it is built as an iron box divided into compartments about three feet square, each connected at the bottom to the next one and with barely enough slope to cause the pulp fed to the first box to gravitate through the machine. An air-basket with a canvas top is placed on the bottom of each compartment and supplies the air for flotation. These 'baskets' are fed by a pipe leading down from a header above the series of compartments, and can be disconnected or removed individually without stopping the ma-

chine, if necessary—the one compartment running empty, with no froth. The main advantage of this machine over the original Callow cell is its tonnage for a given amount of floor-space—a consideration of prime importance in the immense Inspiration mill.

The idea of individual air-baskets for use in what is practically a Callow cell has also been applied in the Hyde and Calaveras modifications. In the Hyde machine each separate wind-box on the bottom is fed through a hose from a header along the top and likewise allows of the removal of an individual air-basket for repairs without stopping the operation. The Calaveras machine is not capable of this arrangement, as the air-feed pipes to the individual air-baskets enter through the bottom of the cell.

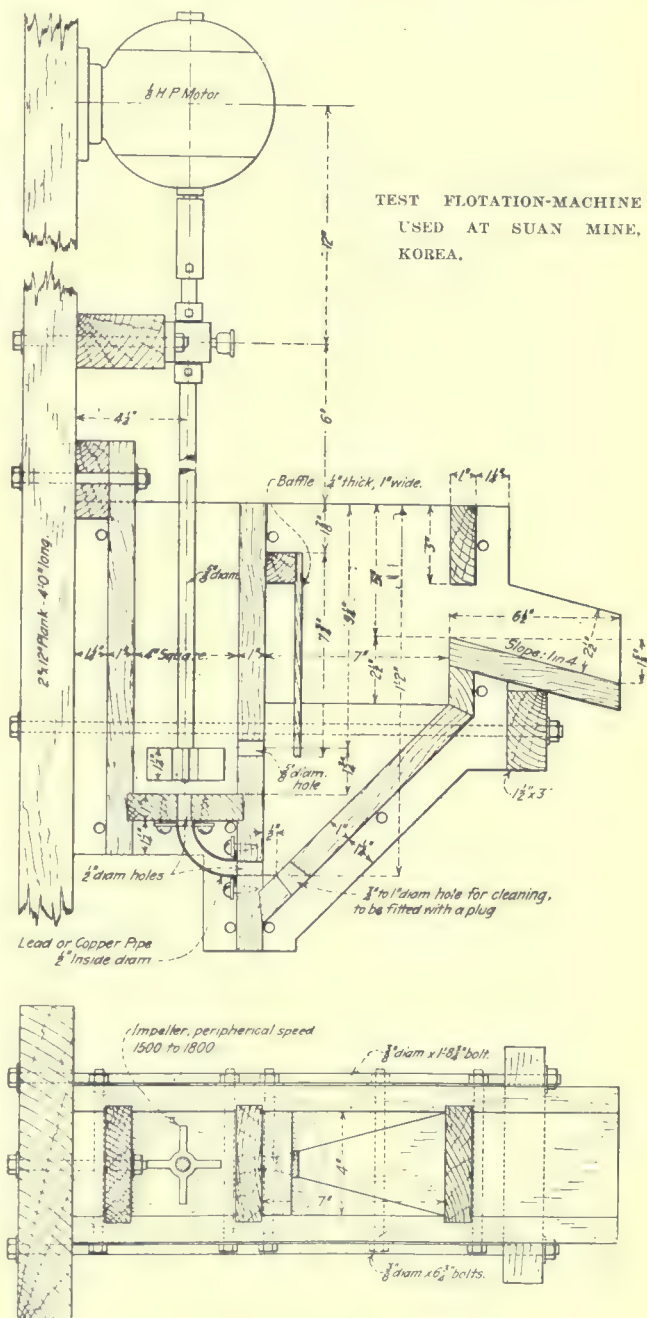

In one of the mills at Cobalt, Ontario, Mr. Callow has lengthened one of his machines from the standard 8-ft. cell to a 30-ft. cell. This in effect makes it a launder with a porous bottom for the introduction of air. With the much smaller slope involved in one of these cells the accumulation of sand would cause trouble, but this particular machine is intended for the treatment of a very finely-ground product that has very little sand in it.

One other pneumatic machine of interest is that used in one of the Belmont mills and designed by George Crerar. It consists of a series of launders about six feet long by one foot wide. The launders have porous bottoms and are placed side by side. The pulp enters the first one, passes through it to the end, then through a hole into the next one and back to the front, thence into the next one and to the back, and so on. This gives a considerable distance of travel in the frothing-launders before the tailing is discharged.

Still another interesting machine is the 'C-B,' named after its designers, Cole and Bergman. It is also pneumatic, but introduces air into the bottom of a cell through pipes that are perforated and wrapped with canvas, in order to break the air into small bubbles. The pipes are spaced across the cell at some distance above the bottom and the sand can sink down between the pipes and be removed from the bottom. This has given rise to its name as the 'frothing classifier.' The present form discharges the whole tailing from the bottom and everything has to pass down between the pipes. Mr. Cole believes that flotation should be used ahead of the tables in a plant treating both sand and slime. The idea is that the fine particles in the slime and some of the coarser mineral will be removed in the flotation-machine and that tabling of the coarse mineral left in the tailing from the flotation-machine should then be an easy matter, and could probably be accomplished without classification. This sounds reasonable, and it suggests the further advantage that when the flotation-machines happen to go wrong for a short period much of the minerals that they do not float would be caught on the tables below. Some engineers have objected that they have not been able to get as good results by following Mr. Cole's plan, claiming that the slimed gangue caused poor tabling work of the mineral sand. This is a point

that needs further elucidation which it doubtless will receive.

A most interesting machine that has been developed to a commercial stage during the past year and is now being sold, is the K. & K., named after its inventors, Kraut and Kohlberg. This machine is agitated mechanically; it has a horizontal drum revolving inside a

cylindrical casing and dipping into the pulp to be agitated. The pulp is whirled between the drum and the casing and thrown through the air at the top into a spitzkasten, where the froth can be skimmed off. Riffles and holes in the drum cause the pulp to be aerated by air drawn out by the centrifugal force. The power consumed by this machine is said to be less than 2 kw-hr. per ton of solid as compared with about 3 kw-hr. per ton for pneumatic machines and nearly 4 kw-hr. for Minerals Separation machines.

The development of differential methods has progressed and there are now several plants in the Northwest treating mixtures of zinc and lead sulphides and making a good separation. Copper and iron sulphides are being separated at several plants in California and elsewhere, and one of the interesting problems remaining is the separation of zinc and iron sulphides. The Sudbury ores are being attacked in the hope of removing either the copper or the nickel sulphides, so that the metallurgical methods of separating the copper and nickel may be changed.

The flotation of oxidized ores has assumed importance. By filming the ore with a solution of a soluble sulphide it is possible to convert oxidized minerals superficially into sulphides that can be floated by the usual flotation methods. At the Magma plant at Superior, Arizona, hydrogen sulphide in small amount is being introduced into the suction of a centrifugal pump for sulphidizing and a good extraction of oxidized copper minerals is obtained. At the Prince Consolidated plant near Pioche, Nevada, a mill is treating oxidized lead-silver-gold mill-tailing with a solution of sodium sulphide followed by flotation. A high extraction of the lead and a lower extraction of the gold and silver are being obtained. The success of the Magma plant doubtless will lead to the use of the process on many other copper ores, and the developments at the Prince Consolidated will be anxiously awaited, as the successful treatment of this lead carbonate ore will probably mean the extension of the process to an ore that it has been difficult to treat successfully.

Flotation has also invaded the field of gold and silver metallurgy. Most of the ores that are difficult to cyanide can be floated, and in some cases the rich minerals can best be concentrated by flotation before being cyanided. The general consensus of opinion seems to be that flotation will prove to be a valuable accessory to cyanidation, rather than a serious competitor. It will permit the preparation of a final product ready for cyanidation that can be treated more carefully in order to lower the consumption of cyanide and other chemicals. This will apply largely to the ores that are difficult to cyanide and that usually demand a considerable amount of time, fine grinding, etc., for their extraction. Gold-field, Cobalt, and Cripple Creek seem to be the leaders in the use of this new method for treating precious-metal ores.

In California, the flotation of mercurial ores is being considered; in Minnesota, it is thought that even magnetite can be floated; in the Black Hills, scheelite may be made to attach itself to the little air-bubbles; in Kentucky, it is thought that possibly fluorite may prove docile; in Pennsylvania, anthracite coal in the culm is now being attacked. Who knows to what other ores this process may be adapted?

The further inroad of flotation and hydro-metallurgy on the smelters is to be expected in the years to come. The difficulties faced by the smelters in the handling of flotation concentrate are leading to proposals to leach

such concentrate without dewatering it. At the Arizona Copper Co.'s plant at Morenci a concentrate of copper sulphide is soon to be leached. One of the prime requisites for rapid hydro-metallurgy is fine division of the material to be treated, whereas this condition creates difficulties in smelting. If the copper smelters wish to hold their own they must be prepared to handle flotation concentrate without penalizing their customers on account of the fineness of their products. Otherwise hydro-metallurgy will invade their field. In fact, the direct production of metal at the mine is the goal of all metallurgy. If crude ore enters at the head of a mill, is concentrated by flotation, and then the flotation concentrate is leached without filtering and drying, one of the worst sources of trouble and annoyance will have been removed and the product of the mill will probably be black copper, or even electrolytic copper. As far as lead and zinc ores are concerned, it will be harder to devise a hydro-metallurgical method that will treat the raw sulphides, but reagents like chlorine are known to be effective in attacking them and the idea is not impracticable. As far as gold and silver are concerned, the idea to cyanide the concentrate is not at all revolutionary and does not seem as radical as the proposal to leach copper or other concentrates.

Taken in its broad aspect, flotation has seen a rapid development in its application to slime generally and to the treatment of disseminated copper ores in particular, but now it is being more seriously considered in the light of a new means to be used in conjunction with other than the gravity type of concentration.

MASSIVE ROCK that is to be used in concrete, or in building structures of various kind, should be carefully investigated as to its fitness for the work. A medium-coarse diorite that, apparently, was firm, upon being placed in a breakwater at Eureka, California, rapidly disintegrated after exposure to the salt water. A microscopic examination of this rock showed that the feldspar was much decayed and kaolinized, which evidently unfitted it for the use to which it had been put. Other similar-appearing rock in the breakwater remained firm under identical conditions. This latter rock, under the microscope, showed the feldspar to be still fresh, or at least little altered. It is probable that due to the tides, the rock of the breakwater was alternately wet and dry, and that the salt, entering the interstitial spaces of the partly decomposed rock, upon drying crystallized and thus gradually brought about the disintegration of the diorite. Here is a good example of the tremendous expansive force of crystallization, notwithstanding the fact that the crystals were of microscopic size.

AN important discovery of copper ore at Little Bay, 200 miles north of St. Johns, Newfoundland, has recently been announced. It is said the deposit is 300 ft. wide containing disseminated-copper sulphide with veins of chalcopyrite 1 to 2 ft. wide running 25% and over in copper.

Metal Production in 1916

Advance statements of the U. S. Geological Survey, covering the past year include the following:

ALASKA

In 1916, Alaska mines made a mineral production valued at \$50,900,000, figures based on estimates made by Alfred H. Brooks. The output of Alaska mines in 1915, which was greater than that of any previous year, was \$32,850,000; the increase in 1916 was therefore over 54%. It was the product of the copper mines that so greatly swelled the mineral production of 1916. This amounted to 120,850,000 lb., valued at \$32,400,000; in 1915 this was 86,500,000 lb., worth \$15,100,000. There was also, however, an increase in gold output, which in 1916 was \$17,050,000; in 1915, \$16,700,000. Of the gold produced in 1916, \$10,640,000 is to be credited to placer mines. The value of the lesser mineral products in 1916 was about as follows: silver, \$950,000; tin, \$120,000; lead, \$110,000; antimony, \$60,000; tungsten, \$50,000; coal, \$30,000; petroleum, marble, gypsum, etc., \$130,000. During 32 years of mining, Alaska has produced \$351,000,000 in gold, silver, copper, and other minerals. Of this amount, \$278,000,000 represents the value of the gold, and \$68,000,000 that of the copper.

It cannot be expected that Alaska will continue to produce so much mineral wealth each year, yet the large amount of preparation made in 1916 for lode and placer mining and the development of the coal-mining industry, now assured, give promise of a continuous healthy growth of the mining industry of the Territory. This is especially true of the Pacific Coast region and of that served by railroads built or under construction.

About 640 placer mines were operated in 1916, employing some 4600 men. All the older districts appear to have held up or increased their output compared with the previous year, except Fairbanks. The increased output is, however, to be credited chiefly to the new camps of Marshall and Tolovana. Thirty-six gold dredges were operated in Alaska in 1916, one more than in 1915—29 in Seward peninsula, three in the Iditarod, and one each in the Ruby, Fairbanks, Circle, and Yentna districts. Of these 36 dredges four were installed in 1916. It is estimated that these dredges produced between \$2,000,000 and \$2,200,000 worth of gold. If the final figures bear out this estimate, it indicates a lower recovery per dredge than in the previous year. In 1915 the 35 dredges mined \$2,330,000 worth of gold.

About 25 gold-lode mines were operated in 1916, compared with 28 in 1915. The value of this gold output increased from \$6,069,000 in 1915 to about \$6,200,000 in 1916. South-eastern Alaska, especially the Juneau district, is still the only centre of large quartz-mining developments in the Territory. Next in importance is the Willow Creek lode district. There was also considerable gold-lode mining on Prince William sound, but a decided falling-off of this industry in the Fairbanks district. Lode-mine owners of Fairbanks are awaiting the cheapening of operating costs, especially of fuel, which will be brought about by the Government railroad.

The enormous copper output from Alaska mines in 1916 has already been referred to. During the year 18 copper mines were operated, compared with 13 in 1915—seven in the Ketchikan district, eight in the Prince William Sound district, and three in the Chitina district. The great output from the Kennecott property, in the Chitina district, overshadowed all other operations. Had the transportation companies and smelters been able to handle the ore, however, many of the smaller copper mines would have made a much greater output.

It is estimated that about 550,000 tons of copper ore was hoisted in 1916.

About 232 tons of stream tin was produced in Alaska in 1916. Of this about 162 tons came from the York district, where two tin dredges were operated, and a third was working on placer ground carrying both tin and gold. Developments were also continued on the Lost River lode-tin mine. The rest of the concentrates were recovered incidentally to placer-gold mining in the Hot Springs district of the lower Tanana basin.

The mining of antimony ore (stibnite) began in Alaska in 1915, and continued in a small way through the first half of 1916. The fall in the price of antimony during mid-summer put an end to most of these operations. About 1460 tons of crude ore was mined and shipped during 1916. Much the larger part of this came from the Fairbanks district.

Though scheelite has long been known to occur in some of the Alaska placers, up to the last two years the demand for it has not been sufficient to encourage its recovery. The recent high price of tungsten has induced Alaskan miners to turn their attention to scheelite deposits. In the fall of 1915 a scheelite-bearing vein was discovered in the Fairbanks district, and its development begun. Later two other scheelite-bearing veins were found in the same district. During the winter some of these scheelite ores were treated in a local mill, and the concentrate was shipped out by parcel post. Scheelite mining was continued during the summer, and the crude ore was shipped out by steamer. Considerable scheelite was also recovered from some of the gold placers at Nome, and a little was produced in other districts. It is estimated that about 50 tons of scheelite concentrate was produced in Alaska during 1916, for which the producers received over \$50,000.

The production of petroleum from the only oil claims patented in Alaska, in the Katalla district, continued in 1916. The operating company was re-organized and more extensive exploitation was undertaken.

About 8000 tons of coal was mined in Alaska during 1916 from half a dozen small mines. The largest producer was the Bluff Point mine, on Cook inlet, where a lignite bed was exploited for the local market. The mining of coal in the lower end of the Matanuska field, for the use of the Alaska Engineering Commission, was also a significant event. This part of the field is already made accessible by the Government railroad, now under construction. The construction of a private railroad from Bering river into the Bering River coal-field was also begun, and a little coal was mined at the south-west end of the Bering River field. Tenders for leases of coal lands in both the Bering River and Matanuska coal-fields under the new law have been received by the Interior Department. Another important event was the completion by the Geological Survey of a detailed examination of the more accessible part of the Nenana coal-field, lying 60 miles south of Fairbanks. All these facts indicate that systematic exploitation of the Alaska coal-fields will soon be undertaken.

ARIZONA

The output of gold, silver, copper, lead, and zinc from mines in Arizona in 1916 had a record total value of nearly \$203,000,000, compared with \$90,806,349 for 1915, according to Victor C. Heikes. The notable output of copper and the high prices of metals both assisted in this increase of 123%. There were record productions also of gold, silver, copper, lead, and zinc.

The production of gold from Arizona mines increased from \$4,166,025 in 1915 to approximately \$4,427,000 in 1916, a gain

of over 6%. The production of gold from copper ores in most counties was naturally greater than in 1915, but there was a marked decrease in the output of bullion from amalgamation and cyanide mills, particularly in Mohave and Maricopa counties. Several new gold mines were added to the list during the year, especially at Oatman, but the production was not sufficient to offset the decline in the output of the older properties.

The production of silver from the mines increased from 5,649,020 oz. in 1915 to a record output of 6,823,000 oz. in 1916. As the market price was much higher, the value increased from \$2,864,053 to nearly \$4,490,000, an increase of nearly 57% in value. There was no great change in the production from the Commonwealth property, which is principally a silver producer, so the increase is to be credited largely to the remarkable output of copper ore.

The mine output of copper surpassed all records and estimates, as it increased from 459,972,295 lb. in 1915 to approximately 693,000,000 lb. in 1916. The value of the output, on account of the unusual market, increased from \$80,495,152 to nearly \$190,000,000. The increase of 135% in the value of copper alone in Arizona was therefore more than the value of the total output of the State in the previous year. All the smelting plants of the State were worked at full capacity, and made much greater shipments of copper bullion.

The mine production of lead increased from 21,738,969 lb. in 1915 to a record production of over 26,000,000 lb. in 1916. The value of this output increased from \$1,021,732 to \$1,768,000, or 73%.

The production of zinc from the mines increased from 18,220,863 lb., valued at \$2,259,387, in 1915 to about 20,980,000 lb., valued at \$2,874,260 in 1916 an increase of nearly 27% in value. The greater part of the zinc ore and concentrates was shipped from the Golconda and Tennessee properties in Mohave county.

Dividends paid to December 1 amounted to nearly \$34,000,000.

CALIFORNIA

The mines of California made an output in gold, silver, copper, lead, and zinc valued in all at \$44,384,000 in 1916, compared with \$32,263,844 in 1915, according to preliminary figures compiled by Charles G. Yale. This is an increase of \$12,120,000 or 38%. Renewed activity has been shown in all branches of metal mining in the State. All the older quartz mines are very active, and a number of new ones have been opened. There is also an apparent tendency to renew drift-mining operations at several points.

The mine figures for gold in 1915 were \$22,442,296. The estimates for 1916 indicate an output of \$22,939,000, an increase of \$497,000, or 6%. The gold yield is the largest in 33 years and, with one exception, the largest in 52 years. The increase is the more notable, because a number of the most productive mines in the Mother Lode section of the State, in Amador county, were closed by labor strikes for nearly 50 days, and the loss entailed by the stoppage of the mills was more than \$500,000. There are over 600 productive metal mines in the State, about evenly divided in number between deep and placer properties. From the deep mines the annual output of ore now exceeds 3,000,000 tons. In value of all metals produced, Shasta is the leading county; and in value of gold output Amador, Nevada, Yuba, Sacramento, Butte, Calaveras, Shasta, and Tuolumne, are the leading counties in the order named.

The placer mines of the State continue to produce about 38% of the annual gold yield. The dredges account for 35% of the total gold yield, or 90% of the placer gold yield. There are now 59 dredges at work in the different fields, the most productive of which are in Yuba, Sacramento, and Butte counties. The yield is declining in the Oroville field and fewer boats are at work, some of them on old dredge tailing.

The silver output is estimated at 2,186,500 oz., valued at \$1,438,700, an increase compared with 1915, of 508,000 oz. in

quantity, and of \$588,000, or 69%, in value. The silver is derived mainly from the smelting of copper, lead, and zinc ores, although some silver is recovered also in gold-mining operations.

The estimated mine yield of copper in 1916 is 62,630,000 lb., valued at \$17,097,990, compared with 40,751,625 lb. in 1915, an increase of 140% in value.

The estimated yield of lead is 13,755,000 lb., valued at \$935,340, an increase in 1916 of 9,176,000 lb., and of \$720,000 or 335%, in value.

The estimated zinc output in 1916 is 14,400,000 lb., valued at \$1,972,800, which is an increase of 1,306,000 lb., and of \$349,140, or 22%, in value, compared with 1915.

COLORADO

The mine output of gold, silver, copper, lead, and zinc in Colorado for 11 months of 1916 and the estimated output for December, according to data compiled by Charles W. Henderson, indicates a yield for the year of \$18,940,000 in gold, 7,620,000 oz. of silver, 70,200,000 lb. of lead (in terms of lead in bullion and lead in leaded-zinc oxide), 8,600,000 lb. of copper, and 130,000,000 lb. of zinc (in terms of spelter and zinc in zinc oxide), with a total value of nearly \$49,000,000 compared with \$22,414,944 in gold, 7,027,972 oz. of silver, 68,810,597 lb. of lead, 7,112,537 lb. of copper, and 104,594,994 lb. of zinc, with a total value of \$43,426,697 in 1915. This shows a decrease of nearly \$3,475,000 in gold, but increases of 592,000 oz. of silver, 1,390,000 lb. of lead, 1,487,000 lb. of copper, and 25,000,000 lb. of zinc. With the increased average value of metals, the values show increases of \$1,451,000 for silver, \$1,540,000 for lead, \$1,103,000 for copper, and \$4,840,000 for zinc.

The tonnage treated by the Globe, Leadville, Pueblo, Durango, and Salida smelters was approximately the same as in 1915, the ore coming from Canada, Colorado, Idaho, South Dakota, and other States, and including a greatly increased quantity of zinc residue from Kansas and Oklahoma zinc smelters. A flotation plant for the treatment of zinc-lead sulphide ores of the San Juan region was built and operated at the Durango smelter during the year. The copper matting plant at Ouray was idle. The United States Zinc Co.'s magnetic wet concentration mill and smelter at Pueblo were actively operated on zinc-lead ores from Colorado and other Western States. The Western zinc-oxide plant at Leadville was operated steadily. The Western Chemical Co.'s acid, magnetic separation, wet-concentration plant, at Denver, was operated steadily at increased capacity, as was the Empire Zinc Co.'s 200-ton magnetic separation plant, at Canon City, both treating chiefly Leadville zinc-lead sulphide ores. The old Rocky Mountain smelter, at Florence, was re-modeled into a plant for the treatment of zinc-lead-copper sulphide ores as an intermediate plant for the River Smelting & Refining Co.'s electrolytic spelter plant at Keokuk, Iowa, and large tonnages of sulphide ores were received from various Colorado counties. Copper ore, copper matte, and cyanide precipitates were shipped to the Omaha smelter, and some copper and lead ores were shipped to Utah plants.

The gold output of Cripple Creek (Teller county) was \$11,800,000, a decrease of \$1,883,000. Development continued at lower depths with the continued gradual lowering of the water-level as the Roosevelt drainage tunnel was advanced toward the Vindicator-Golden Cycle properties. Experimentation with the flotation process was continued by the Vindicator and Portland companies for the treatment of low-grade mine and dump ore. The Golden Cycle cyanidation mill, at Colorado City, and the Portland cyanidation mills, at Colorado Springs and Victor, were operated steadily, but with a decreased output. The yield from the small cyanide plants in the Cripple Creek district was not so large as usual.

Lake county, chiefly Leadville, but including also the Lackawanna Gulch, Sugar Loaf, and St. Kevin lode districts and

the Arkansas River dredge district, produced \$1,760,000 in gold, 3,030,000 oz. of silver, 21,000,000 lb. of lead, 2,600,000 lb. of copper, and 71,000,000 lb. of zinc with a total value of \$15,600,000, against \$2,246,152 in gold, 2,571,002 oz. silver, 20,957,404 lb. of lead, 1,803,423 lb. of copper, and 72,493,178 lb. of zinc, with a total value of \$13,839,401 in 1915. The several ambitious drainage operations by pumping already have resulted in shipments of manganese-silver ore from the Down Town district, and of zinc carbonate from the Fryer Hill district, and the Carbonate Hill drainage will unwater zinc sulphide ores partly developed. The output of zinc carbonate was 106,000 tons of 21.5%, against 82,592 tons of 22.48% in 1915. The zinc sulphide smelting and concentrating ore was 115,000 tons of 21%, as compared with 136,555 tons of 22.09% in 1915. The Derry Ranch dredge, below Malta, continued operations during the year.

The San Juan region of Dolores, La Plata, Ouray, San Juan, and San Miguel counties, produced \$3,000,000 in gold, 2,100,000 oz. of silver, 16,000,000 lb. of lead, 2,700,000 lb. of copper, and 5,300,000 lb. of zinc, valued in all at \$6,900,000, against \$3,834,521 in gold, 2,278,201 oz. of silver, 14,314,363 lb. of lead, 3,517,462 lb. of copper, and 1,382,334 lb. of zinc having a total value of \$6,210,494 in 1915.

Boulder, Gilpin, and Clear Creek counties produced \$1,000,000 in gold, 830,000 oz. of silver, 5,500,000 lb. of lead, 1,200,000 lb. of copper, and 2,500,000 lb. of zinc, as compared with \$1,249,894 in gold, 790,065 oz. of silver, 4,008,744 lb. of lead, 1,094,012 lb. of copper, and 1,516,032 lb. of zinc in 1915. Chaffee county's gold, silver, and lead output fell off, but its copper and zinc yield increased. Pitkin county (Aspen) yielded 570,000 oz. of silver, and 16,600,000 lb. of lead, an increase of 121,000 oz. of silver, but a decrease of 2,700,000 lb. of lead. The yield of Creede (Mineral county) showed improvement over 1915, as did also Gunnison and Hinsdale counties. Summit county's production was \$660,000 in gold, 100,000 oz. of silver, 1,400,000 lb. of lead, 14,000 lb. of copper, and 16,000 lb. of zinc, compared with \$680,144 in gold, 64,223 oz. of silver, 1,916,298 lb. of lead, and 8,597,411 lb. of zinc in 1915. The four dredges at Breckenridge produced about the same output as in 1915, and the shipments of zinc from Breckenridge increased heavily. There was a revival of mining at Kokomo, Robinson, and Montezuma. Eagle county made the largest output since mining began at Red Cliff, in 1879. The output of zinc was 29,000,000 lb., against 11,141,750 lb. in 1915. The Eagle M. & M. Co.'s magnetic separation wet concentration mill was actively operated on ore from the Iron Mask mine, and large quantities of zinc-lead ores were shipped from the Black Iron mine. The Brush Creek silver district was also active again. Lode mines in Park county made an appreciably increased output, particularly of gold, but the placer output decreased somewhat. The London mine, at the head of Mosquito creek, was the principal producing property.

Custer county mines were more active than they had been for several years, and with the commencement of shipments from the Rawley tunnel, Saguache county's yield promises to show increases. Development work in the Platoro district, Conejos county, seems to promise production in 1917.

IDAHO

The value of the mine output of gold, silver, copper, lead, and zinc in Idaho in 1916, according to C. N. Gerry, was over \$47,000,000, an increase of 41% from \$33,328,930 in 1915. There was a record output of silver, lead, and zinc and increased production of copper, but a slight decrease in gold.

The mine production of gold decreased from \$1,179,731 in 1915 to \$1,098,000 in 1916, a decline of 7%. Part of the decrease was due to the smaller placer output from dredging. The gold output from copper ore, lead ore, and lead-zinc ore, however, was increased.

The mine output of silver increased from 11,769,128 oz. in 1915 to approximately 12,500,000 oz. in 1916. As the price of

silver was much above that of 1915, the value of the output increased from \$5,966,948 to \$8,225,000, or 38%. There probably would have been a greater increase in the silver production from lead and lead-zinc ores had it not been for the peculiar smelting conditions during the year, as the Northport smelter, which received the Hercules ore, was being completed, and the Bunker Hill & Sullivan Co. at Kellogg was beginning smelter construction. Each of the following mines produced more than a million ounces of silver: Hercules, Bunker Hill, Morning, Greenhill-Cleveland, Caledonia, and Hecla.

The mine production of copper increased from 6,978,713 lb. in 1915 to over 8,000,000 lb. in 1916. This represents an increase from \$1,221,275 to \$2,184,000, or 79% in value, due to the better price.

The mine output of lead increased from 345,999,466 lb. in 1915 to approximately 362,000,000 lb. in 1916. The value of the lead output increased from \$16,261,975 to \$24,616,000, or about 51%.

The mine production of zinc increased from 70,152,234 lb. in 1915 to approximately 80,000,000 lb. in 1916. The value of the output increased from \$8,699,001 to about \$10,960,000, or 26%.

Incomplete dividends amounted to over \$10,600,000.

Preliminary estimates by John D. Northrup indicate that the quantity of crude petroleum produced and marketed in the oil-fields of the United States in 1916 was 292,300,000-bbl. This quantity is greater by 4% than the corresponding output in 1915. Mr. Northrup estimates that 38% of the 1916 total came from the Oklahoma-Kansas field, 30% from California, and the remaining 32% from the Appalachian, Lima-Indiana, Illinois, northern Texas, northern Louisiana, Gulf Coast, and Rocky Mountain fields.

MONTANA

The value of the output of gold, silver, copper, lead, and zinc from Montana mines in 1916 was over \$145,000,000, which is greater than that of any past yearly output, and an increase over the previous year of over \$62,000,000, or nearly 76%. There were notable increases as well as record outputs in the quantity of silver, copper, lead, and zinc, but a decrease in gold output. These preliminary figures have been prepared by Victor C. Heikes.

The mine output of gold was valued at \$4,635,000, a decrease of nearly 14% from \$5,400,195 in 1915. Much gold came from the Scratch Gravel district and the Piegán-Gloster mine, in Lewis and Clark county, and from the Ruby Gulch and August, in Phillips county. The production of gold from ores milled, was in several places less than in 1915, and even the gold output from silicious ores smelted seems to be declining. The placer-gold output decreased, especially that from dredge operations, though sluicing was begun below Troy, in Lincoln county.

The mine output of silver in Montana increased from 14,378,437 in 1915 to 16,686,000 oz. in 1916. The value, on account of better prices, increased from \$7,289,868 to \$10,979,000, or nearly 51%. Most of this output came from ores and concentrates smelted, especially copper material, in which there was a great increase, but a considerable quantity also came from the lead and zinc concentrate mined at Butte, of which there was a larger production. Work was resumed at the Ophir mine by the Butte Detroit Copper & Zinc Co., and the mill was re-modeled.

The mine production of copper, which is Montana's greatest asset, increased from 267,231,014 lb. in 1915 to 357,000,000 lb. in 1916, an increase of nearly 90,000,000 lb. The increase in value was proportionately more, owing to the unusually high price—from \$46,765,427 to \$97,461,000, an increase of over 108%. Everything was done at both the Anaconda smelters and that of the East Butte company to take advantage of the demand for copper, and at the same time important changes were in progress to improve the output and the

saving. Wages of Butte were increased on a sliding scale making a record pay-roll.

The mine output of lead increased from 13,756,356 lb. in 1915 to a new record of 16,933,000 lb. in 1916. The value of the output was nearly doubled, increasing from \$646,549 to over \$1,151,000, or 78%. A great part of this output came from lead concentrates made from lead-zinc ore at Butte and from residue resulting from the smelting of zinc concentrates from the Butte district. Part of the lead output came from the Iron Mountain mine, in Mineral county.

The mine output of zinc increased from 187,146,895 lb. in 1915 to 227,000,000 lb. in 1916. In value the output increased from \$23,206,215 to \$31,099,000, or 34%. The construction of a large electrolytic zinc plant at Great Falls was progressing rapidly, and at the close of the year three units were complete. The plant is to have five units and will make an output of 6,000,000 lb. of zinc per month. A zinc concentration plant having a capacity of 2000 tons was also constructed.

The main dividend payers were the Anaconda Copper and the Butte & Superior companies, but smaller payments were made by the North Butte and Intermountain or Amador. The Barnes King and Kendall gold mines also paid dividends. The available figures show a total of dividends for the year of over \$26,000,000, but these figures are not yet complete.

NEVADA

The value of the gold, silver, copper, lead, and zinc from the mines of Nevada in 1916 was approximately \$52,475,000, according to Victor C. Heikes. This total represents an increase of nearly \$18,000,000, or about 52% above the corresponding figure for 1915, which was \$34,551,436. There were large increases, and record productions, made in copper, lead, and zinc, but there was a slight decrease in silver and a large decrease in gold.

The mine output of gold was valued at approximately \$9,000,000 in 1916, a decrease of 22% from the output of 1915, which was \$11,404,300. The gold output from copper ore was increased, but that from amalgamation and cyanide mills was less in many of the camps. The production of silver was 13,680,000 oz., a decrease from 14,459,840 oz. in 1915. The value of this output, however, on account of the higher price of silver, increased from \$7,331,139 to \$9,000,000 or 23%. The silver output comes chiefly from the Tonopah district, where there was a marked decrease. In 1915 the district produced 516,337 tons of ore, \$2,228,983 in gold, and 10,171,374 oz. of silver. In 1916 the district produced approximately 448,000 tons of ore, \$1,941,000 in gold, and 8,884,000 oz. of silver. In the Rochester district there was an increase in both gold and silver production. In the Comstock district there was an increase of approximately 60% in the value of the gold and silver output.

The mine production of copper increased from 68,636,370 lb. in 1915 to over 103,000,000 lb. in 1916. The value of the copper increased from \$12,011,365 to \$28,120,000, or 134%.

The mine production of lead increased from 16,637,277 lb. in 1915 to 23,466,000 lb. in 1916. The value of the output increased more than \$800,000, or 104%, over that of 1915, which was \$781,952. A considerable part of this production came, as in former years, from the mines of the Yellow Pine district, in Clark county.

The mine production of zinc was approximately 34,739,000 lb., an increase of over 10,000,000 lb. from that of 1915. There was a greater increase in the value, from \$3,022,680 to \$4,759,000, or 57%.

Incomplete records of dividends paid by Nevada mining companies during the year amounted to \$11,348,000.

NEW MEXICO

The output of New Mexico mines for 11 months of 1916, with an estimate for December, indicates a yield of \$1,350,000 in gold, 1,800,000 oz. of silver, 7,100,000 lb. of lead, 91,400,000 lb. of copper, and 36,500,000 lb. of zinc (in terms of spelter

and zinc in lead-zinc oxide), valued in all at \$33,469,400, compared with \$1,461,105 in gold, 2,005,531 oz. of silver, 4,542,361 lb. of lead, 76,788,366 lb. of copper, and 25,404,064 lb. of zinc, valued in all at \$19,279,468 in 1915. These preliminary figures were compiled by Charles W. Henderson.

The Mogollon district, Socorro county (reached at present from the railroad at Silver City, Grant county, 80 miles distant), continued to be the most productive district in New Mexico in output of gold and silver. There was a great deal of new development done, but the yield decreased appreciably.

The Lordsburg district, Grant county, which has been steadily increasing its shipments of silicious gold and silver bearing copper and other ores, again greatly increased its tonnage shipped. The copper concentrates of the Chino Copper Co., containing as they do small quantities of gold, contributed to the gold yield. The continued activity of the mines and matte smelter at San Pedro, Santa Fe county, also added an increased quantity of gold to the New Mexico yield. Shipments of copper ores from the Jarilla district, Otero county, carried some gold.

The principal metal produced in New Mexico is copper, and since 1910 the yield has been chiefly from the Chino Copper Co.'s low-grade copper deposits at Santa Rita. The ore is milled at Hurley in a large wet-concentration-flotation plant. During 1916 the largest tonnage in the history of the company was treated and the gross output was 75,500,000 lb. The Burro Mountain Copper Co.'s new concentrator began operations in April and started running at full capacity June 1, 1916. The Santa Fe Gold & Copper Co.'s 125-ton matting plant, at San Pedro, added a considerable quantity of copper to the output. Copper ores were also shipped from the Organ Mountain district, Dona Ana county.

The yield of lead showed an appreciable increase. Lead ores were shipped from the Central, San Simon, and Pinos Altos districts, Grant county, and Cooks Peak and Victorio districts, Luna county. Considerable tonnages of lead carbonate ore were shipped from Kelly, Socorro county.

Increased shipments of zinc carbonate and sulphide ores and zinc sulphide were made in New Mexico in 1916. At Kelly, Socorro county, the principal producing mines were the Kelly, Graphic, and Juanita.

OREGON

Preliminary estimates compiled by Charles G. Yale of the San Francisco office of the Survey show increases over 1915 for gold, silver, and copper, and a decrease for lead. The output of gold in 1915 was \$1,861,796 and for 1916 \$1,900,000, an increase of \$38,000. The output of silver in 1915 was 117,947 oz., and in 1916 227,500 oz. The output of copper in 1915 was 451,172 lb., and in 1916, 2,527,000 lb., and the output of lead in 1915 was 62,957 lb., compared with 22,000 lb. in 1916. The increase in gold is merely nominal, but that of silver has about doubled. The most notable increase is in the quantity of copper, an increase caused by the incentive offered by high prices. There are less than 100 productive metal mines in Oregon, and the number of placers is about double that of the deep mines. However, two-thirds of the gold output and virtually all that of the other metals, is derived from deep mines. No very productive new properties have been opened during the year. The entire output of the deep mines is derived from less than 160,000 tons of ore, having an average value of about \$9 per ton. Baker is still the most productive county in the State, yielding annually nearly 90% of all the gold. The Cornucopia and the Baker mines, in the Cornucopia district, Baker county, are the most productive deep mines in Oregon. Other large deep mines in Baker county are those of the Commercial Mining Co. (Rainbow mine), at Rye Valley, in the Mormon Basin district; the Columbia Gold Mines Co. at Sumpter, Cracker Creek district; and the Homestead-Iron Dyke property, at Copperfield, Iron Dyke district. The Powder River Dredge Co., operating two boats near Sumpter, Cracker

Creek district, is the most productive placer mining enterprise in the State. In 1916 a new dredge was under construction in the John Day Valley, Grant county. The most productive hydraulic mine in Oregon is that on the property of the Columbia Mines Co., in Placer district, Josephine county. Other notably productive hydraulic mines are the Martin & Daniels, Galice district, Josephine county, and the Sterling, in Forest Creek district, Jackson county. The gold won by dredging far exceeds that obtained by all other forms of placer mining combined.

SOUTH DAKOTA

The production of gold from mines in South Dakota in 1916 was \$7,463,000, compared with \$7,406,305 in 1915, and that of silver was 209,000 oz., compared with 199,864 oz. in 1915. A nominal quantity of lead was produced. These are preliminary estimates reported by Charles W. Henderson.

The Homestake mine and amalgamation-cyanidation mills were operated continuously throughout the year with an increased output. All the other cyanidation mills in Lawrence county were operated steadily, with the exception of Bismarck. During a part of the year the Deadwood-Standard cyanidation mill was also operated on ore from the Slavonia property.

A small production of placer gold was made in Custer, Lawrence, and Pennington counties. A small yield of lode gold was made from the Hill City district, Pennington county, and considerable development was done in the Keystone district and several small shipments were made.

TEXAS

The output of Texas mines for 11 months of 1916 with the estimated output for December, as shown by preliminary figures reported by Charles W. Henderson, amounted to \$600 in gold, 680,000 oz. of silver, 50,000 lb. of lead, and 100,000 lb. of copper, compared with \$1503 in gold, 675,473 oz. of silver, 219,298 lb. of lead, and 42,491 lb. of copper in 1915. The greater part of the output of silver came from the Presidio silver mine and cyanidation mill, in the Shafter district, Presidio county.

UTAH

Utah mines will close the year 1916 with a record-breaking ore output of gold, silver, copper, lead, and zinc having a total value of about \$97,000,000, as estimated by Victor C. Heikes. This record indicates an increase of nearly 77%, or \$42,000,000 over the output of 1915. All the metals showed increases and there were record outputs of copper, lead, and zinc. About 14,000,000 tons of ore was mined in 1916, against 10,451,445 tons in 1915. The mines at Bingham produced the larger part of this ore, or nearly 13,000,000 tons, mostly by steam-shovel mining. This quantity includes about 12,000,000 tons of disseminated copper ore, the output of which in 1915 amounted to 8,908,567 tons. In all districts many of the old mine and tailing dumps were re-worked or shipped directly to the smelters. Ore shipments from the Tintic district totaled about 400,000 tons, representing an increase of 36% over 1915. The estimate includes a quantity of oxidized iron ore greater than that shipped in any previous year, caused by the demand for flux at the different smelters. Several thousand tons of ore and old dump material that are not included in the estimate were milled in the district. In the Cottonwood and American Fork districts over 47,000 tons of ore of shipping grade was produced in 1916. Nearly half the output was hauled by wagon and tractor-engines down Big Cottonwood canyon to the valley furnaces. The Park City region produced less milling ore and more ore of shipping grade, which, with concentrates from three ore mills and two large tailing plants, amounted to nearly 90,000 tons, a decrease of about 7500 tons from the output of 1915. In 1916 two new mills were erected at Frisco and Newhouse, in Beaver county, to work tailing yielding copper, lead, and zinc concentrates, which, with the ore shipped

from the different mines, aggregated 65,000 tons. This is an increase of more than 46,000 tons over 1915. The ore output in Tooele county, principally at Ophir and the Stockton camps, including the smaller districts, North Tintic, Columbia, Dugway, and Erickson, amounted to 126,000 tons. This included the milling ore of the Ophir and Bullion Coalition properties. There was an increase of 14,000 tons of ore compared with 1915.

The gold output of Utah shows a slight increase, from \$3,609,109 in 1915 to \$3,647,000 in 1916.

The production of silver is 8% greater, increasing from 12,313,205 oz. to 13,357,000 oz., amounting to an increase in value of over \$2,500,000.

Copper production in Utah broke all records, increasing from 187,671,188 to 242,000,000 lb., an increase of 29% in quantity and over \$33,000,000 in value. The gigantic operations by steam-shovel at the great mine of the Utah Copper Co., kept two railroad lines busy hauling an average of 31,000 tons of ore daily to its two concentration mills at Garfield, 15 miles distant. There were days when the ore hauled exceeded 40,000 tons. At Lark, the Ohio Copper mill operated on low-grade copper ores from its mine, which was in the hands of lessees.

Lead production also surpassed all former records, increasing from 199,967,437 to over 215,000,000 lb., the increase amounting to about 7% in quantity and over \$5,000,000 in value.

Prices for zinc continued high during the early part of the year, and much ore and concentrate containing the metal was marketed, but the price broke in May and was low in June, when a general falling off of the production was noticeable until the markets became settled. Altogether there was produced about 29,000,000 lb. of metallic zinc by 39 producers, against 24,292,240 lb. by 34 producers in 1915. The increase in value was nearly \$1,000,000. No new zinc districts were opened in 1916.

Dividends were paid by 22 mining companies, amounting to about \$24,404,320, as against \$9,827,524 in 1915.

WASHINGTON

The value of the mine output of gold, silver, copper, lead, and zinc in Washington increased from \$744,033 in 1915 to approximately \$2,018,000 in 1916, according to the preliminary estimates of C. N. Gerry. This is the record output of the State in value.

The mine production of gold increased from \$391,419 in 1915 to \$540,000 in 1916. The greater part of the gold was derived from the silicious ore shipped to smelters from the Republic district of Ferry county. The cyanide mills were not operated. The silver output of Washington mines increased from 255,837 oz. in 1915 to about 315,000 oz. in 1916.

The mine output of copper increased from 1,020,926 lb. in 1915 to about 2,569,000 lb. in 1916. Since the average price of copper was more than 27c. per pound in 1916, the value of the copper increased from \$178,662 to over \$701,000. Thus copper is now of more importance than gold, which was formerly the principal metal of the State. A large part of the copper output came from the Chewelah district.

The mine production of lead increased from 295,215 lb. to about 4,937,000 lb. The value of the output increased from \$13,875 to about \$336,000. This notable increase was due largely to the discovery of lead at the Electric Point mine, near Northport.

The mine output of zinc increased from 244,906 lb. to 1,709,000 lb., an increase of nearly 600%.

PORTLAND CEMENT manufactured in the United States during 1916 amounted to 91,194,000 bbl., an increase of 5,000,000 bbl. Stocks declined over 3,000,000 bbl. Prices averaged higher and trade conditions were generally better than in 1915; the outlook for 1917 is considered good.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

ROCHESTER, NEVADA

WAGES RAISED.—NEW DEVELOPMENTS AND IMPROVEMENTS.

All of the companies in the Rochester district have increased wages 50c. per day. The increase was granted voluntarily, conditional on silver remaining above 70c. per ounce. The new wage-scale is as follows: Blacksmiths, \$5.50; miners and timber-men, \$5; trammers, muckers, and helpers, \$4.50. The standard rate for board remains at \$35 per month, with \$1 additional for medical and hospital fee.

At last the high price of silver is having its effect on this district; there is more work being done now than at any previous time. It is encouraging to note that much of the new development is being undertaken on the advice of well-known engineers and geologists, and that the flamboyant publicity that marked the early period of the district's history is much less in evidence.

One of the largest deals is now being carried through by Joe Colligan. It involves the bonding or purchase of all the properties lying between the Rochester Mines property and the Packard, over 25 claims in all, including the Packard North Extension, Shepherd, Cold Storage, Enterprise, Jackson, Rochester-Packard Annex Co., and probably the Packard South Extension. There are persistent rumors that the Friedman interests are back of the deal.

The addition to the Rochester mill is not yet completed, shipments of machinery having been delayed. Work on the new tramway commenced December 1. The company announced that it would be completed in 60 days or less. It is to be nearly three miles long, constructed during a period of frequent snow-storms, so that this estimate of time seems rather optimistic. The company developed abundant water at Hardesty springs during the summer, so the mill will not have to face the shortage that curtailed production a year ago. Practically all ore is now being drawn through the Friedman tunnel, eliminating the haulage on the hill tram.

The Merger company has started sinking an incline shaft on a strong vein outcropping on the crest of Nenzel hill, a few feet from the Rochester Mines east side-lines. This is probably destined to have an important bearing on the future work here. The Merger intends to begin the erection of a 100-ton mill in the spring. Sufficient water is available in American canyon, and the company expects to have a surplus to partly fill the needs of the town of Rochester, which is as yet unsupplied with water.—The Nenzel Crown Point is pressing development, and the Elda Fino will begin operations early in the new year. These three companies will work in close harmony and much of their development will be done jointly.

To develop the Octopus ground, a half mile from the Rochester Mines mill, the Rochester Octopus Mines Co. has been organized by Nevada and Utah people. The output so far is 700 tons of \$32.54 ore.

The new refinery of the Packard mill was completed late in December. Concentrate was formerly shipped to the Selby smelter. Specimen ore containing ruby silver, as well as horn silver, is being taken from the recently encountered Kromer-Hampton vein. This vein is undoubtedly the source of the rich surface ore shipped from the Kromer-Hampton lease. A large quantity of ore has been blocked-out on the contact orebody. Jay A. Carpenter is general superintendent.

Some fair ore has been found in the Rochester United.

CASPER, WYOMING

ENCOURAGING OIL DEVELOPMENT IN BIG MUDDY FIELD.

Recent developments in the Big Muddy field have been such as to attract the attention of oil operators and investors from far and near. Big Muddy looms on the horizon as an embryo oil-dome of great promise, and its development along the broad lines now outlined, will, it is confidently believed, within the next few months result in very large production.

Less than a year ago—in fact during the early months of 1916—the first well was started and oil shortly after was discovered in the Shannon sand at a depth of about 1000 ft. This work was done in the face of adverse reports on the possibilities of the structure by many well-informed oil geologists. Only on man, V. H. Barnett, of the U. S. Geological Survey, was willing to stake his reputation. In Bulletin 581-C he discussed the probabilities and possibilities of finding oil in the Wall Creek sandstone, a series productive of good oil in large quantities in the Salt Creek field 50 miles north-west, and which he found to outcrop along the south side of the Big Muddy areas. Although his report was published in 1914, the contradictory contentions of other geologists delayed the starting of drilling.

However, the finding of the first oil was sufficient to encourage further work, and additional rigs were erected on the field. Early results were flattering, which, while determining the Shannon sand to be 'spotted,' developed a number of productive wells. In the meantime three drills had been started for the Wall Creek sand. One of these was erected by the Merritt Oil & Gas Co., another by the Whitesides Co., and the third by the Midwest Refining Co. The Merritt well was the first drilled-in. The Wall Creek sand was encountered at a depth of 3150 ft., and after drilling 16 ft. into the oil-bearing stratum, work was suspended pending the installation of tankage and equipment for caring for the production. This well is now flowing 175 bbl. daily, and it is believed that further drilling will greatly increase the yield. The Wall Creek sand is 125 ft. thick, and an admirable oil container—hence the predictions of greater production.

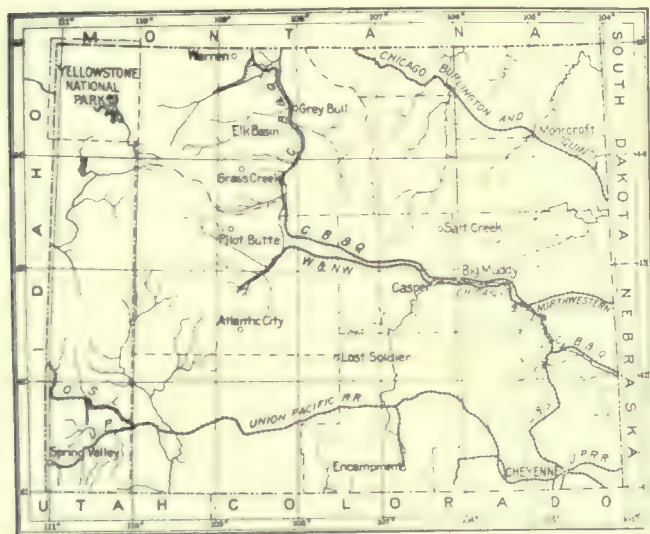

Various troubles were encountered at the Whitesides well, one hole was abandoned at a depth of over 1900 ft., another was lost, and work is now going forward on the third attempt to reach the deep sand. Satisfactory progress has been made at the Midwest well, and it is expected to reach the big sand late in December.

In the meantime at least 25 wells have been finished to the Shannon sand, and are producing 25 to 50 bbl. each; while 10 others have not been productive of oil. At present more than 25 rigs are at work in the field, and recent contracts made by the Midwest, Ohio, and other strong companies call for many additional rigs soon to be engaged in development. High prices have been paid for choice holdings, now that oil has been found, and even the New York Curb has interested itself.

Probably the largest single transaction yet recorded has been the organization of the Merritt Oil Corporation, which has secured the leases and holdings of the original Merritt company and several adjoining tracts. It has been capitalized at 600,000 shares of \$10 par value, and in the first few days of trading on the New York Curb changed hands at prices well above par. It is understood that the Midwest company purchased half of the capital stock at a price of \$2,500,000. Other

important transactions have been the purchase of a half-interest in the Kinney lease—400 acres of school land—by the Ohio Oil Co. for a consideration of \$100,000, and a purchase of one-half of the Elkhorn, by the Midwest, for \$25,000. Subsequent to the Merritt strike—the deal mentioned was made prior to that important find—the Midwest has offered \$250,000 for the other half. The owners want \$300,000, a price the big company has under consideration and may accept.

Big Muddy is favorably situated. It is 20 miles east of Casper, on both the Burlington and Northwestern railways. The present production, except that used as fuel under the

MAP OF WYOMING. EXCEPTING ATLANTIC AND ENCAMPMENT, THE OTHER CENTRES ARE OIL PRODUCERS.

boilers of the drilling rigs working in the field, is shipped by rail to the refinery at this point. There is talk of constructing a refinery at the field, for, although the Midwest is increasing its facilities at Casper, the production will soon exceed the capacity of the plant.

Pilot Butte, Dallas, Lost Soldier, and Brenning have been recent points of oil discovery, while production continues at Salt Creek, Grass Creek, Greybull, Lander, and Hudson. Central Wyoming, with Casper as the logical trading point and centre of activity, will next summer be the scene of further important discoveries. Scouts are working in greater numbers, and almost daily rigs are loaded and hauled to strategic locations "somewhere in the sagebrush."

Wyoming's production of crude oil in 1916 will exceed 7,000,000 bbl. With many wells capped, it is not a far cry to the projected pipe-line to Omaha, Nebraska. In fact, that may be a reality almost before we know it.

TORONTO, ONTARIO

COPPER IN MANITOBA.—MOLYBDENITE IN QUEBEC.—PORCUPINE, BOSTON CREEK, AND COBALT NOTES

The requirements of munition manufacturers have given a great stimulus to the production of copper, zinc, and molybdenum, as well as to the steel industry, and many deposits of these metals, formerly regarded as commercially unavailable, are now being worked. The copper deposit on Schist lake north of The Pas, Manitoba, after having been thoroughly proved by diamond-drilling, is being exploited by the Tonopah Mining Co., which is arranging to take out at least 5000 tons of ore during the winter. It will be hauled for 38 miles to Sturgeon portage, from which it will be conveyed by water to The Pas, and shipped to the smelter at Trail, B. C. The company has placed extensive orders for machinery.—The Mine Centre Copper Co., which holds eight claims near Mine Centre

in the Port Arthur district of Ontario, has shipped six cars to the Trail smelter, the returns from which have been so satisfactory that it has been decided to instal a concentrator during the winter.—On the Mathews property adjoining surface showings indicate a continuance of the vein, and active development is being undertaken.

The demand for molybdenite has produced something like a boom in the staking-out of molybdenite claims in the Quyon, Quebec, district, where there are extensive showings of that mineral. One mine, owned by the Canadian Woods Molybdenite Co., is in operation, producing 180 tons of ore per day. The ore realizes \$30 per ton net. After being separated from the rock, at Renfrew or Ottawa, it is sent to Kingston to be refined, and the finished article turned over to the Government for shipment to England. The deposit is low grade, but nearly all the ore is good enough for milling. Many other claims are being tested with a view to speedy development.

The merger of the McIntyre, McIntyre Extension, and Jupiter mining companies of Porcupine has been arranged, and the terms will be submitted to the shareholders of the McIntyre for ratification on December 28. The Extension is to receive 294,000 McIntyre shares, which is equivalent to 1 share for every 3 1/4 shares of McIntyre Extension outstanding other than already owned by the McIntyre. For the Jupiter the price is 316,298 McIntyre shares, equal to 1 share for every 3 Jupiter shares, exclusive of those held by the McIntyre.—There has been some delay in the construction of the addition to the Hollinger mill owing to labor shortage, but the building is now nearly complete and installation of the machinery will shortly be started. It is expected to be in operation by June next. The Hollinger is now treating 1900 tons per day, and the addition will almost duplicate its capacity. At the Apex diamond-drilling has been started. The main shaft, now down 125 ft., will be sunk to the 300-ft. level, at which cross-cuts will be made to tap veins coming in from the West Dome and Dome Lake.—The Thompson-Krist has let contracts for diamond-drilling to begin early in January.—Diamond-drilling at the Inspiration has reached a depth of 285 ft., the cores showing heavy mineralization.—At the Newray a test pit has been put down 21 ft. on the west side, and assays are stated to give \$36 per ton.—Development of the vein found south of the shaft on the 100-ft. level of the Schumacher shows the high-grade body to be larger than was supposed. Nearly 200 ft. of driving has been done, the vein widening about 12 ft. with an ore-shoot 75 ft. long and 6 ft. wide, stated to be worth \$50 per ton.

At Boston Creek, the Boston Creek Mines is pushing development, having had 50 men at work since May of last year. An incline shaft is down 200 ft., and over 800 ft. of driving and cross-cutting has been done. A winze will be sunk 1000 ft. from the 200-ft. level, and a raise made to the surface to make a new vertical 3-compartment shaft. Rich ore is being taken from the 100-ft. level, where the vein is 12 ft. wide.

The Dominion Reduction Co. has bought a controlling interest in the Caswell property at West Shining Tree, where several rich veins have been found. In one of these at a depth of 20 ft. there is a gold showing 2 in. wide.

At Cobalt the McKinley-Darragh company has placed an order for a new ball-mill, which will take the place of the present 50-stamp mill.—The Buffalo company will install a new 600-ton smelter, the machinery for which was ordered some time ago, but delivery has been delayed.

Dividends paid at Cobalt in 1916 totaled \$4,958,651. Of this, the Beaver contributed \$60,000; Coniagas, \$600,000; Kerr Lake, \$600,000; La Rose, \$299,725; Mining Corporation of Canada, \$570,615; McKinley-Darragh-Savage, \$269,723; Nipissing, \$1,500,000; Peterson Lake, \$168,127; Right of Way, \$16,855; Seneca Superior, \$598,605; Timiskaming, \$225,000; and Trethewey, \$50,000. The total to date of all companies that have operated at Cobalt is \$67,318,853.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU. After over a 5 months' tour of the interior, the Territorial mine inspector, W. Maloney, states that the past season was a good one in all districts. Water was short at first, but after the rain there was plenty. At Nome the Pioneer Mining Co.'s hydraulicking yielded \$200,000 in one clean-up. The Marshall district is promising on one creek. From Iditarod to Ruby there are 500 prospectors busy.

VALDEZ. The last clean-up of the Granite Gold Mining Co. netted between \$11,000 and \$12,000. In addition there are six tons of concentrate estimated at \$174 per ton, that are not included. "The mine is looking better than ever," says the manager, W. R. Millard. The shoot on the 110-ft. level is much stronger than on the 50-ft. level, and the end has not been reached.

Telegraph advice states that a large part of Valdez was destroyed by fire on January 2. Intense cold hampered salvage operations.

WRANGELL. According to J. G. Galvin, general manager of the Bon Alaska Mining Co., who has gone to Seattle to purchase equipment, winter work will be of a preparatory nature. Roads have already been constructed and camps established. High-grade galena has been opened in the Lake group of claims, the vein being 5 ft. wide with good walls. In Groundhog basin, 4 miles inland, a 200-ft. adit has been driven, also trenching on the surface for 3000 ft. The lodes are from 5 to 10 ft. wide. A hydro-electric plant is to be erected at once. Bunkers, etc., will be built on the beach for ore shipments.

ARIZONA

CHLORIDE. The output of this district in 1916 is estimated at \$12,000,000. Of this, \$10,000,000 came from the Tennessee mine. Forty mines are now being worked, 12 others are to begin soon. Three mills of a total of 600-ton capacity are being constructed; two others and a sampling-plant are probable. Railroad business has increased over four times.

DOUGLAS. The population of this centre is 26,100, a large gain during the past year. The town depends on a cultivated valley and two copper smelters—the Copper Queen and Calumet & Arizona. It is a meeting place in the South-west for mining men, and may be an important railroad junction. Across the border in Sonora are large mining regions tributary to Douglas, all helping business there. The *Douglas Daily Despatch* recently published some interesting facts on the smelter town.

OATMAN. Development in the Gold Road Bonanza mentioned last week, was on the 500-ft. level, where a vein was cut by the shaft. Sinking will be continued until the shoot leaves the shaft. Assays yielded \$5.79, \$13.05, \$27, and \$41.79 per ton.

PARKER. In its press bulletin the Parker Bureau of Mines describes conditions in the district, where many large bodies of gold and copper ore have been opened. In the eastern end the Clara Consolidated is shipping several carloads of ore daily, the monthly output being \$60,000. Most of this comes from the 400-ft. level.—Adjoining Clara is the Arizona Revenue Copper Co., a recent consolidation of properties that have good possibilities. On the Echo claims 1500 ft. of work has been done, exposing rich copper ore. The Revenue and Elephant claims also show good ore.—North of the Arizona Revenue property is the Planet mine, controlled by the

Lewisohns. A shaft is down 500 ft. Churn and diamond-drilling results were good. Lessees have the right to mine to a shallow depth, and keep 8 auto-trucks busy carrying ore. Their profit in 6 months is said to be \$200,000.—Other promising properties in the district are the Mexican, Mineral Hill, Continental, Mohawk Con., Pride, Mammon, Empire, and Arizona McGinnis.—A 75-ton mill is being erected for the Billy Mack company.—The Swansea smelter, of 750 to 1000-ton capacity, is still idle, though rumors say that it may soon be blown-in again.—Arrangements have been made and plans are well under way for the installation of a power-plant at Parker to supply the entire district, using oil for fuel, until water-power can be developed from the Colorado river. This plant will probably be started within a few weeks and be rushed to completion, the financing having already been arranged for.

(Special Correspondence.)—The Mile Wide Copper Co., in the Tucson mountains, is to start a 6000-ft. tunnel connecting the Alta valley with the Santa Cruz Valley side of the range. This will reduce the distance of hauling ore and supplies to railroad from 18 to 5 miles. The tunnel will also cut 9 distinct contacts that are exposed on the surface. A Fairbanks-Morse 100-hp. oil-engine and Sullivan angle-type compressor are being installed. This will help exploration on the 200-ft. level. A complete topographical and geological map is being made of the property by W. J. Bloch, assistant superintendent.

Tucson, December 21.

WICKENBURG. The Arizona Sampling & Reduction Co. is erecting a sampling plant here that is almost ready for operation. There is 1800 tons of ore, mostly copper, awaiting sampling. Two Snyder and two Vezin machines do the sampling. In the 50-ton treatment plant there is a Marcy ball-mill, Akins classifier, Wilfley tables, and flotation cells.

ARKANSAS

YELLVILLE. The North Arkansas zinc region produced 93 carloads of ore during November, a record. This is equal to 3000 tons, worth \$65 per ton, or \$195,000.

CALIFORNIA

BISHOP. The Last Burro mine in the Ubehebe district, near the Nevada border, has been taken over by C. E. Knox of the Montana Tonopah company. A hoist, mill, and houses are being erected. Much of the material was shipped in from Los Angeles by way of Bonnie Claire, the nearest railroad point, and then transported to the mine with the aid of a Yuba tractor of the caterpillar type. The mine is 52 miles west of Bonnie Claire. George F. Badgett of Tonopah will have charge of the work. The Last Burro is said to be in condition for shipping.

(Special Correspondence.)—The owners of the McKean mine in Siskiyou county are negotiating for the Dressler property at the head of Eagle creek in Trinity county, 7 miles distant. Dressler & Ingram are the owners of the property, which comprises two well-developed claims. There is a strong vein of high-grade sulphide ore that is amenable to cyanidation. The owners of the Yellow Rose, which adjoins the Doraleska and is situated partly in Trinity county and partly in Siskiyou, will drive a lower adit next year to reach the rich ore-shoot discovered in the upper workings years ago. This shoot yielded ore in 1902 that milled \$18 per ton and shipping ore

that gave \$1600. It has a serpentine-porphry contact, the hanging wall being porphyry and the foot-wall serpentine. The new adit will be 400 ft. long and will give 150 ft. additional backs.—The Jubilee mine has been shut-down for the season, but will resume in the spring as early as the weather permits. The cause of the shut-down was the freezing of the water in the ditch, but that will be remedied this coming year. The ditch will be widened and a flume or pipe-line built part of the way. It will be widened sufficiently to supply the 150-hp. electric plant that is to be built in the coming summer. The compressor and mill will be operated electrically instead of by water; also the ore-cars. The lower adit, No. 5, is in 800 ft., and will be continued until the ore-shoot of No. 4 adit is encountered. It will be the main working outlet. At a distance of 750 ft. from the portal a 4-ft. vein of commercial ore was cut. The Jubilee ore contains telluride. Laboratory tests give 97% extraction. The ore of Poeth mine, which adjoins the Jubilee and is also under bond to the California Extraction Co., is likewise a telluride ore, and gives a laboratory extraction of 95%. The mill is equipped with 10 stamps, to which will be added a tube-mill. The Vandercook process will be used, in which amalgamation precedes cyanidation. Herbert E. Noll is superintendent and John Botticher foreman. Coffee, December 13.

(Special Correspondence.)—The work of installing the plant of the Grass Valley Consolidated Mines Co. at the Allison

of ore, which yielded bullion \$2217, and 37 tons of concentrate \$2730. There was collected on assessment No. 39, \$7178. The total income was \$12,142. Out of this the expenditure was \$10,487.

The treasury has a balance of \$8264. Sinking the shaft from 3200 ft. for 150 ft. commenced on November 20; good progress is being made. Development and ore extraction is under way on the 1800, 2700, 2825, 3000, 3100, and 3200-ft. levels. The new hammer-drills in use in the 1800-ft. west cross-cut are doing good work. The tailing reservoir was reinforced during the month, and the flume trestle thoroughly overhauled and graded, as it had settled at some points.

Preparations are well under way for sinking the Bunker Hill shaft an additional 600 ft., this work to start early in January. Indications on the lower levels are excellent for the development of large reserves of high-grade ore below the 2400-ft., which is now the lowest level. Until the strike occurred in September, the Bunker Hill had not missed a single monthly dividend for nearly nine years, and with the shaft extended to the 3000-ft. level, there is reason to expect not only the resumption of dividend-payments on a generous scale, but the building up of a large surplus as well. The permanent shaft repairs and surface improvements recently made have brought working costs down to a low figure. The following prominent Amador County men are the officers of this company: W. F. Detert, president; E. C. Voorheis, vice-president; Benj. F.

PLANT UNDER CONSTRUCTION AT THE ALLISON RANCH MINE, GRASS VALLEY.

Ranch mine is now over 70% complete, the various units being mostly under cover. Owing to slow freight shipment, the transformers are not here, delaying unwatering; but the large centrifugal pump, with a capacity of 1000 gal. per minute, is in place. The water already has been lowered over 100 ft. by the siphon method. Work on the electric tramway, which will connect the head-frame with the ore-bins, high on the bluff above the stamp-mill, is under way. By the time the plant is ready to operate the company will have expended approximately \$110,000, exclusive of the purchase prices of the Allison Ranch and adjoining properties.

Grass Valley, December 23.

REDDING. Next spring L. Gardella is to build another dredge on Clear creek, moving one from Oroville.

(Special Correspondence.)—The Central Eureka Mining Co. has issued its November report, showing that work was resumed at the mines on the 6th, and 20 stamps of the 40-stamp mill began crushing on the 20th. There was treated 1781 tons

Taylor, Arthur Goodall, and Chas. L. Culbert, directors; and E. Hampton, secretary and superintendent.

A new pump has been installed and the shaft crew increased at the Hardenburg mine, south of Jackson. The W. J. Loring Co. is the present operator.

Immediately after Christmas, operations are to be resumed at the Poundstone or Rose mine, a mile east of Sutter Creek. San Franciscans and a Mr. Stone of Goldfield, Nevada, have taken an option on the property, and have agreed to sink the main working-shaft 1000 ft. If good ore is found while doing this, the new company will build a mill and sink a new shaft for further development. L. R. Poundstone of Grimes, Colusa county, is the owner, and he has had just enough men employed since the cessation of operations a few months ago to keep the shaft unwatered. Besides a 20-stamp mill, the Poundstone property is equipped with a small hoist and the usual mining machinery.

Sutter Creek, December 24.

IDAHO

Dividends paid by companies in the Coeur d'Alene region were as under:

Company	1916	1915	To date
Bunker Hill & Sullivan	\$1,726,750	\$1,062,750	\$18,489,750
Caledonia	911,750	677,300	1,794,481
Federal	510,000	480,000	15,795,495
Hecla	1,555,000	565,000	5,305,000
Hercules	3,000,000	2,250,000	10,250,000
Interstate-Callahan	2,789,940	2,557,445	5,347,385
Intermountain	16,208		16,208
Stewart		804,934	1,981,507
Success	345,000	555,000	2,173,000
Tamarack & Custer	71,050		71,050
Total	\$10,925,698	\$8,952,429	\$61,223,876

HAILEY. The Federal Mining & Smelting Co. is shipping concentrate from its North Star mill in the Wood River district to Colorado smelters. The ore is complex, containing lead, zinc, silver, gold, and iron, and its treatment is now on a satisfactory basis.

WALLACE. The firm of Twohy Bros. of Portland, Oregon, has been awarded the contract to construct a railway up Pine creek for the Oregon-Washington Railroad & Navigation Co. The line will run from the road at the mouth of the creek to the Constitution mine, 10 miles. The three largest mines in the Pine Creek district are the Highland-Surprise, Douglas, and Constitution. Others are developing well.

During the quarter ended October 31, 1916, the Federal Mining & Smelting Co. at Wallace shipped 35,304 tons of ore and concentrate. The profit was \$410,007, less \$64,363 for depreciation.

MISSOURI

JOPLIN. Zinc-ore prices declined again last week, a total of \$25 per ton in three weeks. The output of the Missouri-Kansas-Oklahoma region was 6164 tons of blende, 232 tons of calamine, and 847 tons of lead, averaging \$80, \$45, and \$90 per ton, respectively. The total value was \$596,682.

NEVADA

On Sunday, December 24, a storm in the White mountains of California destroyed several miles of transmission-lines and towers owned by the Nevada-California Power Co., which supplies Goldfield, Tonopah, and other mining districts. In the meantime all power and light was cut off. Connection was established again on Thursday, the 28th. Owing to the trouble Tonopah mines only treated 3431 tons of ore, valued at \$68,620, about 30% of the normal weekly output. Water rose considerably in the Extension mine, but the electric pumps will soon move this. The Belmont shipped 112,558 oz. of bullion. During the year ended September 30, 1916, the Jim Butler Tonopah Mining Co.'s output was 11,637 oz. of gold and 1,055,235 oz. of silver, from 46,489 tons of ore. Dividends totaled \$343,604. Ore reserves are estimated at 19,158 tons.

GOLDFIELD. Final figures of the Goldfield Consolidated for November show that the profit from 30,000 tons of ore was \$15,137. The cost was \$4.54 per ton, including 4c. for filter and 4c. for flotation royalty. Development covered 1705 ft., costing \$5.63 per foot.

(Special Correspondence.)—Construction of the Boss Mining Co.'s 10-ton mill has been practically completed, and it is scheduled to go into commission about January 15. Delays in securing equipment from Los Angeles prevented an earlier start. Considerable copper-bearing ore is being developed, the product containing some gold and platinum. R. J. Goodwin is in charge of the plant.—Work at the Boss Extension is proceeding. The tunnel is in 250 ft., and the shaft is now 40 ft. deep. It is near the side-line of the Boss mine. Some fair ore

has been encountered, and A. E. Buys and Nicholas Kunz, two of the largest owners, are directing work.

John A. Egger has been appointed superintendent of the Oro Amigo, which has recently developed into one of the best properties of the district. A good tonnage of profitable ore is on the dumps and blocked-out underground, and preparations are being made for regular shipments. Besides good copper and silver-content, the ore contains platinum, gold, and palladium.

—The Knickerbocker and Poppy claims, adjoining the Oro Amigo, have been acquired by the Poppy-Knickerbocker Platinum Mining Co., controlled largely by Henry Robbins of Pasadena, California, and Joseph Sanders, H. K. Riddall, and Otto F. Schwartz of Goodsprings. Good ore is indicated and development will be pushed. The property lies near the Keystone group, formerly a noted gold producer.

Heavy shipments of silver-lead-zinc ore are going out from the Yellow Pine mine, and the new reduction plant is operating satisfactorily. The Christmas Consolidated Co. has started developments on the Mt. Queen mine, where ore containing lead and some vanadium was lately found.

Developments throughout the district are extensive, with numerous companies on the shipping list.

Goodsprings, December 20.

TONOPAH. Some fast work was done recently on the 850-ft. level of the Monarch-Pittsburg mine, where 101 ft. was driven in 7 days. Three shifts employed one machine-man and one shoveler. This drift is to make a connection that will improve ventilation and enable rapid development of an ore-shoot.

YERINGTON. The Nevada-Douglas company is employing 300 men at its mines and treatment plant.

NEW MEXICO

(Special Correspondence.)—During the first half of December the Socorro M. & M. Co. produced 14,000 oz. of gold-silver bullion.—The Mogollon M. Co.'s product for the same period was 10,000 oz. of bullion, with several tons of high-grade concentrate.

The head-frame at the Pacific mine has been raised, permitting dumping of the ore direct into the new crushing plant. The new aerial tram to the Socorro mill is in regular operation.

The Myrtle shaft has been re-timbered by the Oaks company, and sinking is now in progress. The showing justifies the belief that milling ore will be encountered in the near future. Myrtle adjoins Maud S, and is a continuation of the Deep Down-Maud S vein, which has an accredited production of \$1,000,000. The Maud S, closed for 18 years, flourished in the early days of pan amalgamation and operated on a high grade of ore which, in spite of the then high extraction losses, made a handsome profit. It is understood that the mine contains a large tonnage of what was passed over in those days as second-grade ore.

Mogollon, December 19.

OREGON

HUNTINGTON. The Conner Creek Mining Co., which has been mining \$6 to \$8 ore for two years, crushing it in a 5-stamp mill, recently extracted gold worth \$100,000 in 4 days. The shoot, at 175 ft. depth, is 20 ft. long and from 15 to 20 in. wide. The mine is 15 miles from Huntington, in Baker county, near the Idaho border.

UTAH

In its 82-page annual number *The Salt Lake Tribune* devotes 14 pages to a review of mining in the State, covering outputs of the principal mines and districts, dividends, and share dealings.

BINGHAM. Owing to storms the Utah Copper Co. was forced to suspend operations at its mines and mills last week.

ALTA. The new railroad to this district is practically completed, only four miles from Tanner's Flat to Alta remaining to

be constructed. There is 12 ft. of snow in the town, but in places there is 40 ft. on the main highway. Snow-slides have been reported. Ore shipments are suspended.

COLTON. The Shearer interests of New York will complete their bond on the claims of the Utah Ozokerite Co. in Carbon county.

WASHINGTON

CHEWELAH. Instead of sinking a two-compartment shaft 500 ft. below the 1000-ft. level the United Copper company will sink three compartments. The plant will have a capacity of 2000 ft. The new mill of 150-ton capacity is ready for treatment. December profits were \$24,000.

NORTHPORT. Since the smelter resumed work here there has been a great expansion in mining, and 1000 claims have been the scene of assessment work and development. The town has a population of 2000, a 300% increase. Three furnaces at the smelter employ 400 men. There are several good lead-silver mines in the district.

CANADA

BRITISH COLUMBIA

HEDLEY. On December 30 the Hedley Gold Mining Co. pays a dividend of 3% for the quarter, plus 2% extra.

ILLECILLEWAET. The new 150-ton mill of the Lanark Mining Co. is more than half completed, and will probably be ready for service not later than February 1. The company is controlled by Spokane interests. Large quantities of ore are ready for treatment, but because the mountain is too steep to permit of storing much ore, there has not been much work done in the mine pending erection of the mill.

YUKON

DAWSON. On December 1, with the temperature 20° below zero, the Canadian Klondyke company's four dredges were still at work. Three boats on the Klondike river may work for some time yet, as the ground is not frozen; but the boat on Hunker creek is digging gravel that has to be thawed by steam, and may cease during December. During the winter, repairs will be made in the shops, the dam and power-plant will be added to, and wood will be hauled.

To extend and strengthen the field of its graduate work in engineering, the University of Illinois at Urbana maintains 14 Engineering Experiment Station research fellowships. One other such fellowship has been established under the patronage of the Illinois Gas Association. These fellowships, for each of which there is an annual stipend of \$500, are open to graduates of approved American and foreign universities and technical schools. Appointments to these fellowships are made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the degree of master of science will be conferred. Not more than half of the time of the research fellow is required in connection with the work of the department to which they are assigned, the remainder being available for graduate study.

The 1917 Northwest Mining Convention will be held at Spokane, February 19 to 25. This is the most important mining event in the North-west, and is attended by mining men from the north-western States, British Columbia, and Alaska. Exhibits of ores, minerals, machinery, apparatus, and supplies are made, and there are four days of sessions devoted to the mining industry. The engineering societies hold technical sessions, there are stereopticon lectures for evenings, and the entertainment of visitors by a special committee. F. C. Bailey is secretary of the Northwest Mining Association at Spokane.

The Massachusetts Institute of Technology (Boston Tech) has issued its catalogue for December. In the 530 pages are detailed every phase of the institution's activities.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

J. M. CALLOW is here.

W. H. ALDRIDGE is in Nevada.

FORBES RICKARD is in Arizona.

WILLIAM FORSTNER has gone to Yuma county, Arizona.

CHARLES BUTTERS has returned to Oakland from London.

JOHN W. MERCER has returned to New York from Ecuador.

C. A. HEBERLEIN, lately at Baker City, Oregon, has gone to Los Angeles.

ALBERT L. WATERS has gone to the Hayden and Globe districts, Arizona.

J. K. TURNER has been examining the Arizona Ray property at Ray, Arizona.

D. R. THOMAS has been appointed manager of the Davidson mine at Porcupine, Ontario.

A. E. RAU-ROESLER is operating the White Oak at Bagby in Mariposa county, California.

C. D. KAEDING, manager of the Dome mine, Porcupine, has been on a visit to San Francisco.

J. H. ROSE has been appointed metallurgist for the Mason Valley company at Thompson, Nevada.

HOWLAND BANCROFT has closed his office at Oruro, Peru, and is now at New York, whence he will return to Denver early in February.

FRANCIS CHURCH LINCOLN, director of the Mackay School of Mines, Nevada, is examining mines in Ontario, Canada, returning to Reno on January 8.

H. H. NICHOLSON, consulting engineer for the Plinco Copper M. & M. Co. of Plumas county, passed through San Francisco recently on his way to Lincoln, Nebraska.

F. K. BRUNTON has resigned from the staff from the A. S. & R. Co. at Garfield, Utah, to become assistant superintendent for the Consolidated Arizona company at Humboldt, Arizona.

L. D. RICKETTS, president of the American Institute of Mining Engineers, will be present at the forthcoming meeting of the local section of the Institute, on January 9, and will deliver an address.

The U. S. Civil Service Commission announces an open competitive examination by January 16, 1917, for supervising mining engineer and metallurgist. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Bureau of Mines, Department of the Interior, for service in the field, at a salary of \$4000 a year, and vacancies as they may occur in positions requiring similar qualifications, unless it is found to be in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. The duties of this position will be to take charge of one of the mining experiment stations. Competitors will not be required to report for examination at any place, but will be rated on the following subjects, which will have the relative weights indicated: (1) education, 30; (2) professional experience, 50; and (3) publications, reports, or thesis, 20; total, 100.

The U. S. Civil Service Commission announces an open competitive examination for assistant examiner in the Patent Office, on January 17, 18, and 19. From the register of eligibles resulting from this examination certification will be made to fill vacancies as they may occur in this position at the entrance salary of \$1500 per year, in the United States Patent Office, Washington, D. C. As the supply of eligibles for this position has not been equal to the demand, qualified persons are urged to enter this examination. Subjects are physics, mathematics, technics, chemistry, French or German, and mechanical drawing.

THE METAL MARKET

METAL PRICES

San Francisco, January 2.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	35
Pig lead, cents per pound.....	7.75-8.75
Platinum, soft and hard metal, per ounce.....	\$85-91
Quicksilver, per flask of 75 lb.....	\$80
Spelter, cents per pound.....	12
Tin, cents per pound.....	43
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, January 2.

Antimony, 50% metal, per unit.....	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	15.00
Magnesite, crude, per ton.....	6.50-9.00
Manganese, 50% (under 35% metal not desired).....	16.00
Tungsten, 60% WO ₃ , per unit.....	18.00-20.00

There is no change in the tungsten market. Antimony remains unchanged but with an outlook for somewhat lower price.

EASTERN METAL MARKET

(By wire from New York.)

January 2.—Copper is easy; consumers are offering; lead is dull and drifting; spelter is quiet, sellers outnumber buyers.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending				
Dec. 27.....	75.37	Nov. 21.....	71.79		
" 28.....	75.37	" 28.....	73.43		
" 29.....	75.37	Dec. 5.....	75.05		
" 30.....	75.37	" 12.....	75.37		
" 31 Sunday.....		" 19.....	76.35		
Jan. 1 Holiday.....		" 26.....	76.05		
" 2.....	75.37	Jan. 2.....	75.37		

Monthly averages							
	1914.	1915.	1916.		1914.	1915.	1916.
Jan.	57.58	48.85	56.76	July	54.90	47.52	63.06
Feb.	57.53	48.45	56.74	Aug.	54.35	47.11	66.07
Mch.	58.01	50.61	57.89	Sept.	53.75	48.77	68.51
Apr.	58.52	50.25	64.37	Oct.	51.12	49.40	67.86
May	58.21	49.87	74.27	Nov.	49.12	51.88	71.60
June	56.43	49.03	65.04	Dec.	49.27	55.34	75.70

Throughout the week the silver quotations have remained unchanged, indicating a market without feature. A drop of 218 lakhs in the Indian treasury and the near approach of the Chinese new year are largely responsible for the steady and uneventful market.

LEAD

Lead is quoted in cents per pound, New York delivery.

Date.				Average week ending	
Dec. 27.....		7.50	Nov. 21.....	7.02	
" 28.....		7.45	" 28.....	7.21

On Thursday, January 4, 1917, the Bunker Hill & Sullivan Mining Co. will pay dividend No. 242 of \$81,750. On the same day the company will pay an extra dividend, No. 243, of \$81,750. This brings the total dividends paid to date to \$18,653,250.

The lead content of ore mined in 1916 is estimated at 622,000 short tons. Missouri was the largest producer, gaining 25% over the previous year. Gains were also made by California, Idaho, Nevada, Utah, and New Mexico. The average price for lead during 1916 was 50% higher than in 1915.

The United States Smelting, Refining & Mining Co. has de-

clared a quarterly dividend of \$1.25 a share on common stock and a regular quarterly dividend of 87½c. on preferred stock, both payable January 15.

June	38.60	90.00	74.70	Dec.	53.10	123.00	80.00				

The quicksilver market remained steady and unchanged throughout December at \$80, with no indication of an early change.

The output of quicksilver for 1916 was 23,942 flasks valued at \$3,643,800. It was the largest output since 1904, and the highest in value since 1875.

The New Idria company paid a dividend of \$1 per share December 30.

Eastern Metal Market

New York, December 27, 1916.

The holiday quiet has been accentuated by the closing of the New York and London metal exchanges over Christmas, including what is known as 'Boxing Day' in London, or the day following Christmas day. This means that no cables were transmitted. Generally the trade is awaiting developments.

Second hands have been making the market in copper, and they have done business down to 31c. for prompt electrolytic. While dull, the market seems to be becoming firmer. The recent break was in part due to weak-kneed consumers who sought to sell because they feared a big drop in prices, and by speculative offerings, the latter, in some cases, applying to future deliveries of metal which the would-be sellers do not hold. In other words, short selling.

Zinc became very soft last week, and rather good buying resulted, but since then the market has stiffened. Dealers were the principal sellers.

Lead is almost without feature, except that the leading interest is willing to sell for February delivery, settlement to be on the basis of its average quotation for that month.

The tin trade is disturbed over Great Britain's decision to conceal, so far as possible, the arrival and departure of ships in her ports.

Antimony is dull. Aluminum is easier.

Recent events have combined to make the steel market a trifle quieter, though not nearly so quiet as is usual around the holidays. Specifications against contracts are as strong as ever. Deliveries are everywhere being halted or delayed by the freight situation. Given signs of a congestion, and a railroad immediately declares an embargo; and shippers are at sea. Lack of coke has caused the banking of many blast-furnaces, 19 of these belonging to the Steel Corporation. Less interest is being shown in extended deliveries, either of steel products or pig iron. Prices hold firm.

COPPER

Re-sale electrolytic has been offered down to 31c. for spot, 30c. for first quarter, and 29c. to 29.50c. for second quarter. Business was done at these figures late last week, but this week the market has been quieter. The metal in second hands is not so plentiful, and the holders have more faith in the future of prices. Some of the selling has been done on behalf of timorous consumers and some by speculators, a few of the latter seeking to sell short on futures, a phase of the situation which producers in particular, do not like. Lake is at the same level as electrolytic in a general way, although some high-grade Lake is held at higher figures. Around the prices mentioned the market is steadier. It is felt that the producers must adhere to their pegged prices in view of their sold-up conditions, also because any concessions offered by them at this time would have a tendency to demoralize the market. The New York and London metal exchanges have been closed since last Friday, and the absence of cabled information has accentuated the holiday aspect of the past few days. The London quotation for spot electrolytic this morning (December 27) was £152 against £161 eight days ago. Finished brass and copper prices are as strong as ever; hot-rolled sheet-copper being held at 42c. and cold-rolled at 43c., delivery at the convenience of the mills.

ZINC

Just before the Christmas holiday forward zinc was fairly active at lower prices. January to June was sold at 9c. to 9.12½c. St. Louis, and first quarter at 9.25c. St. Louis. Prompt continued reasonably firm, and yesterday (December 26) all positions showed less tendency to sag. At the low prices mentioned dealers were the principal sellers, but since the market

has taken on a better tone the producers have evinced a willingness to sell also. The New York quotation for prompt yesterday was 9.75c., and that at St. Louis 9.50c. First quarter has sold this week at 9.37½c. to 9.50c., St. Louis. Operations in the West, including the making of shipments, are greatly hampered by transportation troubles. These are not only those imposed by the weather, but by the shortage of cars. Of the latter, there is country-wide complaint. There were no cables from London yesterday because of the 'Boxing Day' holiday, while the New York Metal Exchange was closed also; consequently no export figures are available at this writing. Sheet-zinc is unchanged at 21c. per lb. carload lots, f.o.b. mills, 8% off for cash. The quotation for spot-zinc at London today (December 27) was £51 10s.

LEAD

The general quotations for nearby delivery are 7.50c., New York, and 7.30c. to 7.40c., St. Louis. For prompt metal shipped out of warehouse in New York premiums are paid because of the paucity of such stocks. The A. S. & R. Co. is selling only for February delivery, for which settlement is to be on the basis of the average of its February quotations. Future lead is neglected and the prices easy. The London quotation for spot lead is unchanged at £30 10s.

TIN

The most important development in this metal that has come about in a long time is expected to result from the action of Great Britain, announced this week, in placing a ban upon shipping news. This means that ships will arrive at and sail from British ports without the fact being known. British vessels will sail for American ports, but sailings will not be reported and will not be known until the vessels arrive in American waters. Likewise, the time of arrival at ports on the other side will be kept secret. The object, of course, is to protect shipping from the activities of German raiders. It will keep importers and dealers in the dark as to the metal they have *en route* from London, and also hide more or less metal on the way from the Far East. The trade is puzzled over how the plan will work out, but wonders why it was not put into effect before. Except on December 20, the past week has been very quiet, and prices have declined. On the day mentioned, 400 to 500 tons changed hands, mostly May and June deliveries from the Far East, for which 40.5c. was the average price paid. The spot quotation for Straits yesterday was 40.87½c.

ANTIMONY

The market is stagnant. The nominal quotation for Asiatic grades is 14 to 14.25c., duty paid.

ALUMINUM

Quotations are easier at 60c. to 63c. for No. 1 virgin aluminum, 98 to 99% pure.

ORES

Tungsten. Inquiry continues to come from both domestic and export buyers. For the home market a considerable quantity has been taken at \$17.50 per unit, and several hundred tons are under option to export buyers at the same price. English buyers are particularly anxious to obtain ore.

Molybdenite. The market is firm, with offerings limited. Quotations are unchanged at \$1.80 to \$2 per lb. MoS₂ contained.

Antimony. The quotation is unchanged at about \$1.70 per unit in a dull market.

COAL OUTPUT of Canada during 1916 is estimated at 14,365,000 tons, an increase of 8%. Alberta, British Columbia, and Nova Scotia are the principal producing provinces.

Industrial Notes

Information supplied by the manufacturers.

New Type of Drill-Sharpener

A new design of pneumatic drill-sharpener has recently been developed by the Denver Rock Drill Manufacturing Co., and is now on the market. It consists of a pneumatic dolly-hammer and swaging-ram mounted on a single pedestal. This

THE NEW DRILL-SHARPENER.

ram not only operates the swaging-dies, but it also clamps the steel and operates the steel cutter. The ram-piston cylinder is fixed directly above the die-blocks, which the manufacturers claim not only gives it a powerful clamping effect, but is also responsible for the effectiveness of this machine under low air-pressures. The ram-piston is returned to its upward position by two small constant-pressure pistons, and when a blow is struck with the ram, or is brought down for the purpose of clamping the steel, the air in these constant pressure-cylinders is merely forced back into the pipe-line. The dolly-hammer is of the valveless type, and uses the air expansively, which characterizes this machine. No springs are used in connection with the dollies, as they are returned by a small constant-pressure piston. This feature facilitates the changing of dol-

lies, as there is no spring-pressure to overcome, and it also eliminates all trouble from spring breakage. All the operations of the machine are controlled by a single lever, which is so situated that the operator can readily observe the workings of the steel. There is but a single air-connection to the machine, which consists of a flexible hose. No exhaust-pipe is required, as the air is exhausted into the hollow base of the pedestal, and this is so muffled as to be hardly noticeable. The manufacturers have also developed a smaller drill-sharpener which they expect to put on the market in the near future.

Commercial Paragraphs

THE GENERAL ENGINEERING Co. of Salt Lake City is to prepare plans for another 500-ton unit at the Consolidated Copper-mines property at Ely, Nevada.

STEPHENSON & NICHOLS of San Francisco have been appointed representatives for the Terry Steam Turbine Co. of Hartford, Connecticut, in northern and central California.

In Bulletin 263 the CHICAGO PNEUMATIC TOOL Co. describes the Boyer railway speed recorder. This can be fixed to any mine ground tramway. Bulletin 34-W covers Giant fuel-oil engines, their parts and applications.

In Bulletin No. 48,703 the GENERAL ELECTRIC Co. discusses its 'fabroil gears,' which are used in all types of machinery. This material, which consists of a cotton filler compressed under hydraulic pressure, has been in successful use for five years.

THE NATIONAL TUBE Co. of Pittsburg has been showing moving pictures illustrating the manufacture of its pipe from ore to finished product, before the Case School of Applied Science at Cleveland, and the National Association of Stationary Engineers at Coplay, Pennsylvania. We remember seeing similar films at the Panama-Pacific Exposition in 1915.

EDITORIAL

T. A. RICKARD, Editor

THOMAS W. LAWSON has revived his hippodrome, and Congress is the principal performer. The talk of a 'remedy' sounds like the echo of a familiar fake.

IN our issue of December 30, the "profit" of the Miami Copper Company on ore treated by flotation should have been "value of concentrate" resulting from this treatment.

DIVIDENDS aggregating \$100,000,000 were paid in 1916 by the mines in five of our Western States—Arizona, Utah, Montana, Nevada, and Idaho. Arizona alone contributed \$34,000,000 to the owners of mines. Every western State shows an increase of metal output and Alaska contributed \$50,000,000 or 50% in excess of the previous year.

AT this season of the year the average man is deluged with statistics that exhaust his fund of wonderment. To those that follow the growth of industry in a great country like this the big totals are not stupifying. When 100,000,000 active and energetic people do anything, whether it be eating candy or producing copper, the statistical record is bound to run into tremendous figures.

MANY ways have been suggested of filling stopes—with waste-rock broken underground, with tailing-sand and other materials taken from the surface, but the latest suggestion comes from an ingenious fellow who proposes to fill mine excavations with ice. He has secured a patent on this cool idea. We don't like it; it would work against the minority shareholders, for it might facilitate a freeze-out.

CALIFORNIA did well in 1916. The gross metal output increased by \$12,000,000 or 38%. The yield of gold was the largest in 33 years, the silver output advanced 69% in value, value of the copper output was 140% bigger, and the lead value was 335% greater, while zinc more than held its own, improving 22% in value. Dredging contributed 90% of the total alluvial gold. We published the details in our last issue, as compiled by Mr. Charles G. Yale, statistician to the Geological Survey.

SPELTER production in 1916, according to the U. S. Geological Survey, was 658,000 tons, as compared with 489,519 tons in 1915. The domestic consumption increased from 364,382 to 445,000 tons and the export from 132,323 to 210,500 tons. Thus production increased 34%, exports 59%, and domestic consumption 22%. In 1913 the production was 346,676 tons, the consumption

295,270 tons, and the export only 7783 tons. The number of retorts in service was 213,840 at the end of 1916, and 13,648 more are being built or planned. This will represent an increase of 70,920 retorts since the end of 1915. At the average of 13.7 cents per pound the total production was worth \$180,000,000, as compared with a valuation of \$121,000,000 in the preceding year.

COPPER mining gave its supporters \$157,000,000 in the form of dividends in 1916, the largest distributor being the Utah Copper Company, which paid \$19,000,000. Kennecott was second and Anaconda third. In the last month of the year the disseminated-copper mines paid an aggregate of \$33,000,000 in dividends. To the gains from copper-mining must be added the dividends of the big metallurgical companies that also operate copper mines, making the total winnings from this branch of the mining industry about \$175,000,000.

SCARCITY of cyanide is tending to restrict the production of silver, particularly in Mexico. This important chemical is now selling for 75 cents per pound and is difficult to get even at that high price. The Glasgow maker of cyanide is restricting his dealings to mining companies within the British empire and the New Jersey manufacturer is supplying far too little to fill the requirements of mills in the United States and Mexico. The decrease in the recovery of silver by cyanidation is diminishing the output of the metal and is one reason for the rise in price. 'Dollar silver' is not unlikely during 1917, for the expense of maritime transport has been increased by the advance of insurance and the purchases of the metal for coinage by the Entente nations is making insistent demands on the supply. The saving of silver by the poorer people of Europe during the War may have some of the effects so long noted from similar hoarding in the Orient.

REFERENCE to two technical articles, published in old volumes of a leading technical society, prompts a protest. We had to read the articles in order to extract some information and we found them most difficult to understand because, apart from being badly written, they contained a variety of weights and measures. In one of them milreis, pounds, shillings, pence, metres, feet, inches, kilograms (written "k."), grams (written "grm."), ounces, and grains made a nightmare of confusion and the text was (we use the past tense because we want to forget it) sprinkled with such illuminating terms as *lapa*, *canga*, and *passador*. In the other article the weights were given in dry and wet tons, in metric

tons and in short tons, while money-values were stated in pounds, dollars, and Mexican dollars (meaning 'pesos') until the reader cursed the tower of Babel and the laziness of writers that will not reduce weights and measures to a common standard, and the one his readers are most likely to know.

AS if we had not troubles enough, we are importuned by a circular from the office of the Institute to vote on simplified spelling, in consequence of a petition presented by a number of honorable members, a suspiciously large proportion of whom live at or near Palo Alto, California. Being a Sherlock Holmes in our own quiet way, we can infer who was the member that conspired to bother us with this spelling propaganda. If the petition is endorsed, we shall proffer our sincere sympathy to Mr. Bradley Stoughton and his staff; meanwhile we rejoice that no faddists can compel us to mutilate the official language of the United States.

EXPORT returns for the first ten months of 1916 indicate the stimulating effect of the War on the metal trade. Aluminum comes first in alphabetic order and it is also the metal exhibiting the greatest gain in exportation, for during the period specified the exports were valued at \$9,542,030, as against \$3,069,270 and \$897,569 respectively in the corresponding periods of 1915 and 1914. Much of this trade has been prompted by the employment of aluminum dust for combination with ammonium nitrate to make the new and deadly explosive called ammonal. Other comparative statistics of metals and manufactures of them are as follows:

	1916	1914
Copper	\$188,866,885	\$103,671,870
Zinc	48,451,130	4,713,944
Lead	14,677,387	4,486,310
Nickel	11,556,454	8,392,042

Brass manufactures, in which so much copper and zinc were consumed, were exported to the value of \$263,337,207 during the ten months of 1916, as against only \$5,336,794 in the same time during 1915. These brass exports were 50 times larger than in 1914. Most of this was the direct result of the business in shells and other munitions.

FROM London we learn that the great lawsuit, which occupied 144 days and in which counsel for the defense made a speech 45 days long, has been decided. The Globe & Phoenix Gold Mining Company wins. It is said that the Judge's life was insured for \$150,000 against the risk of the case being re-heard. That may be a pleasantry, but the cost of the action—\$500,000—is not. An appeal is threatened by the plaintiff and loser, the Amalgamated Properties of Rhodesia. After spending a vast amount of time in hearing evidence on the extra-lateral right phase of the argument and listening to a mass of geological and pseudo-geological testimony, the Court brushes all these mining technicalities aside and decides the case on the terms of the agreement between the two companies, giving the possessor of the claims the benefit

of the proverbial nine points of the law. The mine has been worked for 20 years, so that much of the necessary evidence regarding the vein-structure has been obscured or removed. The old dispute as between the junction of veins and the branching of a main vein called forth discrepant opinions and observations from witnesses of varying positiveness. The giving of the wrong color to a particular vein on a map and the assumption by some of the witnesses that this was a separate lode-unit is stated by the Judge to have misled the plaintiff's experts into trying "to convert an impression into a conviction." All this sounds a familiar note. The immediate result was to debase Amalgamated shares to 6 cents and to elevate Globe & Phoenix to \$9 per share, as against previous prices, last year, of 43 cents and \$5, respectively. Incidentally the study of structural geology in the gold mines of Rhodesia has been stimulated.

The Flotation Crisis

A month has elapsed since the Supreme Court's decision giving Minerals Separation the right to collect royalty from those using less than 1% of oil in a process for making a mineral-bearing froth by means of beating air into a metallurgic pulp. That decision emphasizes the "critical" proportion of oil essential to the success of the operation and sustains only the claims that specify the quantity of oil as "a fraction of 1%," invalidating the three claims in which "a small quantity" is mentioned. Parenthetically, it is worthy of remark that the Court states that the process of patent 835,120 "was immediately generally accepted as so great an advance over any process known before that . . . it promptly came into extensive use . . . in most, if not all, of the principal mining countries of the world, notably in the United States." The fact is that the process did not come into use in the United States until six years after the grant of patent, and as late as the same year—1911—the Minerals Separation people stated that ores containing copper in the form of chalcocite were not amenable to their process. The Court refers to "the Elmore oil flotation process" as "typical of the then prior art" and makes the mistake of ignoring the fact that the old bulk-oil process had been discarded at least ten years ago, while at the same time no reference is made to the Elmore air-oil process that was patented a year before Minerals Separation's principal patent, 835,120, and was put into extensive and successful use in many parts of the world. It is extraordinary how this blunder of confusing Elmore's two methods, one metallurgically a failure and the other a success, one dated 1898 and the other 1904, has been repeated again and again in technical literature and in the courts. There never has been a legal test between Minerals Separation's froth-agitation patent and that of the Elmore vacuum patent. To us it seems astonishing that the opposers of Minerals Separation's effort, now temporarily successful, to obtain a monopoly of rights to the use of flotation, should have failed to avail themselves of Elmore's priority in the use of air with a

small proportion of oil, reduced finally to as little as three pounds per ton of ore. Wisdom after the event was never better illustrated than in the purchase of Elmore's air patents by Messrs. Jackling, Channing, and others for \$75,000 in 1915 instead of doing so before the Hyde and Miami lawsuits were started. It would have been cheaper to buy them for \$750,000 before the litigation had progressed so far. We understand that the Butte & Superior and Miami controllers were loth to establish Mr. Francis E. Elmore's rights and so exchange one patent-monopoly for another, but it should have been possible to settle with Mr. Elmore and his backers before doing so, thereby giving themselves a better chance to win against Minerals Separation. Now the Elmore vacuum patent is mentioned as a means of reprisal and a suit for infringement is likely to be brought against Minerals Separation—reversing the tables. So

“Chaos umpire sits

And by decision more embroils the fray.”

We hope that a suit will be started, if it offers any chance of a more reasonable attitude on the part of the patent-owners. To somebody the users of flotation ought to pay tribute for the use of this wonderful process. It is the harshness of Minerals Separation's policy that has evoked so much antagonism, more particularly the effort to bind metallurgists hand and foot and the attempt to place an embargo upon technical information. A royalty of 10 cents per ton on base-metal ores and of 25 cents per ounce of gold should be paid cheerfully by any user of flotation to the inventor of the process. We do not regard the Court's decision in the matter as acceptable, however correct on the evidence submitted to it. As a detached, but not ignorant, onlooker we would give 4 cents to Minerals Separation, 3 cents to Elmore, 2 cents to Froment's widow, and 1 cent per ton to the Belgian Relief Commission. That might be called an equitable distribution of another man's property.

The Presidency of the Institute

In the December bulletin of the Institute it was announced that the Committee on Nominations, while naming Mr. Sidney J. Jennings for President, regretted its inability, by the terms of the constitution, to nominate another candidate, because it would have liked to name Mr. Philip N. Moore also. It was stated that both gentlemen had received many cordial endorsements and in view of these facts the Committee suggested that Mr. Moore be nominated by petition of 25 members in accordance with the present constitution. The Board of Directors has expressed no preference for either candidate. The Committee, however, intimates that “the nominations are largely controlled by a small group and that the members at large can have little influence.” This was the very condition of affairs that the re-organization four years ago was intended to obviate, but it is only fair to add that the chairman of the Committee is a Californian

engineer of enviable reputation and there is no reason whatever to believe that the nominations were influenced from New York. Owing to the confusion created in the first place by the early electioneering in behalf of one candidate and the later campaigning for the other, a kind of competition has been aroused that can do no good to either candidate or to the Institute. The circular issued by the friends of Mr. Jennings is in bad taste; a possible President should need no touting—Mr. Jennings needs none; his photograph should not be used like that of a candidate for town-constable; moreover, the reference to his ability to ensure “the co-operation of great business enterprises” is unfortunate, because the friends of Mr. Moore have animadverted on the corporation tie, just as the other side has referred to the controversy of four years ago—the movement for reform—in which Mr. Moore played a useful part. In the circular issued by four of the reformers—we speak of friends with whom we are in sympathy—advocating the election of Mr. Moore, it is stated that he was endorsed by a much greater number than Mr. Jennings and members are reminded that the next summer meeting is to be held at St. Louis, where Mr. Moore lives, as another reason for giving him the vote. These are the facts. We have received several letters from engineers of high standing expressing chagrin that the election should have assumed a cheap political character, that either candidate should so strive to obtain the honor, and that an old feud should be revived. We echo these regrets. The presidency should come to a man as an unsolicited honor; it is not the kind of distinction that should be put up to competition, because it is not a dignity for which a man should compete. While it may seem desirable to give the membership at large a chance to express their individual opinions, we doubt whether that can be done usefully. Not many men of presidential rank would be willing to run a race in popularity against a member of their own standing. One cannot imagine James Douglas or James F. Kemp consenting to compete against each other. Putting the argument on a lower plane, most self-respecting men would be unwilling to run the risk of being defeated in such a public contest even by an admittedly eminent compeer. The Presidency is not a political office; it is an honorable appointment made by a committee of engineers selected for their ability to make a proper choice. The Presidency is now no longer a sinecure; it involves work and personal expense, because the holder of the office must attend frequent meetings of the directorate and of committees at headquarters. That is why, inevitably, the president will be more often a resident in New York and its vicinity than a Western engineer or metallurgist. Few men not under retainer to the big corporations or otherwise in their employ are likely to have the time and opportunity to accept the responsibilities of the position. That is why, prejudiced as we ourselves are against any corporate influence in professional affairs, we recognize that the corporation slur is unwarranted, except for specific reasons. It is a pity that the honor must go to rich men or to those that are highly salaried, but that is the way of the world, and fortunately

a comfortable bank account need not kill ethical ideas or professional ideals. So, while we would like to have seen Mr. Moore elected because he is a Western engineer and because his name was mentioned for the presidency two years ago, we do not hesitate to advise the members of the Institute to vote for the regular nominee and we hope most sincerely that Mr. Moore will set aside any personal resentment aroused by the untoward train of events and withdraw from the contest before it is too late, without any condition or promise, leaving it to the sense of justice and good feeling among the membership of the Institute to rectify matters at a later date.

Mining Law Revision

On another page we publish a vigorous and not altogether courteous protest from Mr. Horace V. Winchell against sundry remarks of ours on the proposed amendment of the mining law. We do not resent the unrestrained vigor of his letter because we happen to be aware that the matter is one that he has much at heart and it is one to which he has devoted much time and talent. Mr. Winchell quotes Mr. W. H. Dickson's opinion of the existing law in order to prove how ignorant we are, but he knows, as well as we do, that more than one lawyer of equal authority could be quoted against a change and in support of the contention that the present law is understood, that is, as well understood as any law dealing with technical conditions of the greatest complexity. It is probable that any new law would have to undergo the baptism of much litigation before its intent would be as clear as that of the one that has now been interpreted by multitudinous decisions. The Latin tag at the end of our learned correspondent's communication pays excessive compliment to the "mind shrouded in the densest ignorance of the subject." We confess that our knowledge of the law and its incidence is much less than that of Mr. Winchell, who has supplemented his experience as a geological witness in the courts with a careful study of the whole subject in its bearing upon the inequities perpetrated in the course of aberrant adjudication, but he is without the one qualification that those less minutely informed may possess, and that is a detached view of this contentious subject. Injustice there has been, of course, but a good deal of justice also; and we have no expectation that any law can be passed that will be unerringly fair, simply because human motives are disregarded by the blind lady with the scales. Our remarks concerning the gentlemen in New York have given umbrage, but is it not proper to insist that they see only one aspect of a many-sided problem and that others equally interested, such as prospectors and mine-operators, are in no way clamorous for the reform that Mr. Winchell and his friends insist upon? Thirty years ago their propaganda would have been timely. At this late date the public mineral domain is a vanishing quantity; the Government cannot withdraw what it has given; a new law would apply successfully only to new districts, while introducing fresh complications into the

ownership of claims in the old districts. Here we are reminded of the wearisome law-suit recently concluded in London, between two Rhodesian mining companies, in the course of which the extra-lateral right was involved. Is it not a fact that the extra-lateral right was introduced into the mining law of that new country on the advice of American mining engineers, at least one of whom has been a member of a committee to reform the law in the United States? Leaving this phase of the subject we may mention that a leading member of the Mining and Metallurgical Society has written to ask how the prospector's opportunity may be enlarged and how the idle holding of claims may be discouraged or penalized. These are pertinent queries. The modification of 'discovery' as a preliminary to location might help the prospector, but, as a matter of fact, it has been already excused by tacit consent of the mining community in such districts as Leadville and Tonopah, where outcrops are scarce. The courts protect possession where the claimant is working in good faith, but the informal agreement to disregard this requirement of discovery is no bar to the Government's right of possession in case the law has not been observed. The location of a group of claims without discovery, the protection of possessory rights pending proof of mineral character, and the postponement of patent until ore has been found would operate like the French *permis de recherche*, or permit to explore, previous to selection of a definite and smaller area as the place of systematic mining. Such a regulation, if embodied in statutory form might help the prospector, although the courts already give him the benefit of the doubt. On the other hand, we can suggest no way of compelling work on idle claims, except for the State and County to pile taxes on the owners of them. This is done, in effect, by assessors, who make it harder for the non-resident owner of property than for the resident. The Government cannot deprive the non-operative owner of his patented claim except by condemnation for public utility, for anything else would be contrary to the constitutional inhibition that you shall not deprive a man of his property without due process of law. On the whole, it seems to us that the easing of the 'discovery' requirement before location is about the most practicable reform. It is already a dead letter in a few districts and as laws derive their force from public opinion, this part of the law is quietly ignored in some parts of the country. An enactment relieving the prospector of the obligation to discover mineral where the geologic conditions did not permit a ready disclosure would simplify matters and give him a more reasonable opportunity to extend his activities under legal protection. It would give him the right, with his partners, to hold enough ground long enough to enable him to find ore in place and so qualify his claims for patent. The miner's right to hold locations without discovery should depend upon his doing the requisite assessment work, as now, and showing good faith in the search for ore by sinking or cross-cutting, so as to check more unproductive alienation of the land. We shall be glad to have Mr. Winchell's ideas on the matter.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Re-Location Habit

The Editor:

Sir—I read not long since in some paper that California has passed a law which makes it illegal for the owner of an unpatented mining claim on which the annual assessment work has not been done, to re-locate such claim within three years from the date of his failure to perform the required annual work. I consider this a 'bully' law, and one that other States would do well to add to their statutes. It eliminates the 'claim hog' and gives the fellow a chance who is willing to do work on a prospect. I have known of men claiming anywhere from three or four to over a hundred locations in one district and not doing work on more than one or two, and sometimes on none at all. Each year they go around and re-locate, talk like a 'bad-man-from-Bodie,' and bluff peaceful men, who are looking for a reasonable prospect and not a gun-fight. In one district I knew an old cuss—a rank bluffer—who did no work, but claimed 160 locations. It would have required annual labor or improvements to the amount of \$16,000 and he didn't have \$16. It is such men as this who retard the legitimate development of mining districts. I am for the law that demands from claim holders that they do the work required by the law or get out, and give another man who will, a chance.

NIL DESPERANDUM.

Rochford, S. D., December 23.

Mining Law Revision

The Editor:

Sir—In your editorial columns of December 23, I read with some amusement and more impatience the following statement regarding the Federal mining law: "The old law, defective as it may be, has been filtered through the courts until its intent is clear."

The same idea has found expression in several of your recent issues. It is to be presumed that some of your readers are accustomed to place a degree of confidence in the statements in your editorials, and others are likely to quote them as authoritative whether they believe them or not. It is not my intention or desire at this time to enter into an extended discussion of the subject. I wish to make but one criticism of the statement which is quoted above. It is not only untrue but so far from the truth as to be absurd, and can emanate only from a mind shrouded in the densest ignorance of the subject. I make this assertion of my own knowledge,

but if further authority is needed I beg to refer you to the statement of Hon. W. H. Dickson of Salt Lake City, perhaps the most experienced mining attorney in the United States (Doc. No. 233, 64th Congress, p. 58): "The statute has now been in force nearly forty-four years and notwithstanding the great multitude of litigated cases that have risen out of it, its true meaning or interpretation is still unsettled as to many questions." And again after referring to several unsettled points, he says: "The foregoing are some of the questions of law yet undetermined. Doubtless there are many others—but if every question as to the true interpretation of the act and its application to any and all conditions to every state of facts which might be established, were finally settled, it would not greatly curtail the volume of litigation arising out of it."

Verbum sat sapienti.

HORACE V. WINCHELL.

Minneapolis, December 28.

[In our last issue we asked for frank criticism; here is some of it, and it is welcome.—EDITOR.]

Pan-Americanism

The Editor:

Sir—Have just finished reading your editorial of November 18, on 'Pan-Americanism—A Myth,' which was received while I was away. As you know, I am very much interested in the South American countries and in our export trade with them, therefore, I believe that while many of the things you stated in your editorial are basically true, your conclusions are not justified.

The South American countries are farther away from the United States than they are from Europe, but that is no reason why we should not extend our trade with them. Their racial characteristics are more allied to the southern Latin countries of Europe than they are to us, but trade is carried on between South America and Europe, not with the Latin countries, but with Germany and England, which are farther removed in respect to kinship than we are. Commerce does find the cheapest markets and if we are to hold any trade, we must come into competition with the producing countries of Europe. We are able to do this even in Europe itself. Shall we then decline to try and meet that competition in South America, China, and Africa because in the past we have held such a small proportion of the trade with those places? Rather, I should say, we should bend every effort to increase our trade with those countries and had

we done so during the last three years much of that trade would be definitely linked with us and never would return to the channels it had before the War.

That we do produce the things that South America wants is shown by the large amount of business we have done in those countries since the European war cut them off from trading with Europe. But we do not give them as good service as the European countries did because we have not studied and tried to understand their conditions. On my recent trip on the west coast of South America I had the opportunity of meeting many merchants and business men and discussing the question with them. One of them had just received a consignment of paint from a New York house. The paint had not been properly packed, the cases not even being strapped, with the result that not one quarter of the order could be used. This merchant said to me, "We want to trade with the United States but look at the condition in which we receive goods ordered; they tell us we can collect insurance and they will help us, but we don't want the insurance, we need the goods and need them badly." This simply goes to show that we do not understand the arduous handling to which goods are subjected and make no provision for same. The buyers in those countries are willing to pay extra, and glad to do so, for the proper packing and protection of goods.

On the train going up to Bolivia I met several traveling-men from the United States. They could neither speak nor understand Spanish, and yet they were going up to sell goods to people who speak and think only in Spanish. Suppose the average merchant in this country were approached by a traveling-man who could only talk Spanish. He wouldn't even be given a hearing.

As we are an exporting nation and every year are becoming more so, it behooves us to look to all fields. Because Germany sends more goods to the United States than she does to South America, she does not neglect the South American field. So it must be with us. We must study and train a corps of men to introduce our products to South America. We must understand them and do business as they want to do it. Once the average South American gets to do business with houses that he knows and which treat him rightly, he is a confirmed customer and it is a hard thing to get him to change. So with the chance we now have, we should bend every energy to extend and make fast our business relations with our South American relations.

South America produces a great deal that we need, and while it is true that a good part goes to Europe, it is also true that a good part comes back from Europe to us. Why cannot we take these raw products and make them up here and use what we need and export the rest? Of course, there are many adverse conditions to be met but if we are to develop an export trade, we must expect to be in active competition with the rest of the world and I know of no better field than right in South America for trying our powers of competition. We do not have to neglect Europe, or for that matter, the rest of the world in pushing our exports—the whole world

is the meeting place of those that are engaged in trade.

Nor should we neglect building up a merchant marine or giving proper protection to the business houses and their representatives who go abroad for new business. We need every encouragement and all possible help to meet competition but I believe we are able and can meet it fairly and squarely.

N. DICKERMAN.

San Francisco, January 2.

Some Pertinent Questions

The Editor:

Sir—How many mine superintendents can correctly answer, off-hand, the following questions:

How many feet of drilling should be done by a miner on an 8-hour shift working with a single-hand hammer?

With a drill of the jack-hammer type?

With a 3½-inch piston-drill, using 90 lb. of air pressure?

How long a time should a shoveler take to fill a car of 1800 lb. capacity with ordinary quartz ore, or rock, shoveling from the rock floor of a drift?

What is the average cost of shoveling a ton of rock into a car from a rough floor underground when no shoveling-plank or metal sheet is used?

What is the increase of efficiency if a shoveling-floor of plank, or a metal sheet is used?

How far is it safe to carry the face of a drift beyond the last set of timbers?

How far should a trammer push a loaded car on a fair track underground in one minute?

What is the best angle of inclination for a raise that is to be used for the passage of ore or rock?

How many cubic feet of quartz in place are required to weigh one ton?

How many feet, if broken?

How many cubic feet of fresh air per minute should be sent to the face of a drift where two men are at work, where the place is lighted by candles—one for each man?

What number of hours of actual work per shift results in the greatest efficiency of men?

How far apart should loading-chutes be placed on a level to get the greatest economy in handling ore in the stope above?

Is the bonus-system advisable in underground work? If so, why? If not, why?

Is the contract-system in mining work a good one? If so, why?

Copperopolis, December 9.

THE PUTTY-KNIFE of the glazier is a most convenient and effective implement with which to clean-up amalgam plates. It is flexible and readily removes the accumulated amalgam and is much less likely to scratch the plate than the chisels made from old rasps, so commonly used in cleaning-up in stamp-mills.

THE SHOVEL CREEK DREDGE, SHOWING ANGULAR CHARACTER OF GRAVEL AND THE LIMESTONE BEDROCK.

Dredging for Gold on Seward Peninsula, Alaska—Season 1916

By Corey C. Brayton

Gold dredging on Seward Peninsula is unique. This land area is the most western of the American continent and lies just below the Arctic circle. Gold was discovered at Nome, the chief distributing-point and centre of mining activity, about the time dredging was started at Oroville in California. The first mining, of course, was done by pick and shovel, either on surface or underground, and this method was entirely satisfactory except under unfavorable conditions, such as low gold contents, and difficult or impossible drainage.

It was only natural that miners should soon turn to machinery in order to increase their output. All kinds of mechanical equipment were built and tried, principally on the beach, and along the Snake river, which had several rich tributaries. None of this early machinery, however, was satisfactory. The first successful dredge was built by W. L. Leland, of the Three Friends company, (now the Seward Dredging Co.) on Solomon river. This was a 5-ft. Californian standard machine, steam-driven. It is still operating, but is now using electricity generated by a Diesel plant on shore. Since then the number of successful dredges has increased rapidly, until now there are 34 in operation.

Conditions on Seward Peninsula differ from those in California, or, for that matter, from any other region in the world. Dredging is confined principally to narrow but comparatively rich creek deposits. The areas are small; the depth is shallow, averaging about 8 ft.; the season is only four months, and both labor and power

are expensive. Operating costs necessarily are high, but so also is the grade of the gravel.

The chief difficulties are operating during a short cold period before the final freeze-up, and digging gravel too shallow for floating the dredge. The cold is not so serious, but the shallowness of the gravel often involves digging into hard barren bedrock, or the construction of dams, to secure the necessary depth. The building of dams is usual and is neither excessively expensive nor difficult.

The operation of a dredge in shallow ground presents a great many problems that the operator accustomed to deep ground does not have to face. It is like the contrast between shallow and deep-water navigation. The operator accustomed to deep ground has to forget a good many things and adapt himself to new and different conditions.

The Californian type of dredge was not well adapted to the conditions on the Peninsula, though there are places in which it is used. It was necessary to develop a dredge suited to the special conditions. In general the shallow and loose gravel is easily dug and does not require the strength of the Californian machine; moreover, the gold is usually coarse and does not demand the large table area of the Californian dredge. These two conditions, together with the smallness of the alluvial areas, made it advisable to employ a light-weight cheaply constructed machine, and this is the sort of machine in use.

MAP OF THE SEWARD PENINSULA, SHOWING POSITION OF DREDGES.

In California, the first dredges were both too small and too light in construction to suit local conditions. On Seward Peninsula, it was necessary to revert to the lighter type; it was simply a matter of adapting the dredge to existing conditions. The favorite type of dredge in use on the Peninsula is known as the 'flume' dredge. In this machine a flume takes the place of hopper, screen, tables, and stacker. A variation of this type is the combination flume-stacker, which, in addition to the flume, has a short screen with two or three-inch perforations and a flat stacker. To one accustomed to seeing or operating the Californian type of dredge, these small machines look flimsy and inadequate, but, on the contrary, they fit the conditions, and all things considered, are efficient.

With two exceptions, power is obtained from internal-combustion engines on the dredge itself. The fuel consumed by the majority of these power-plants is distillate, but the Diesel and other types of oil-engine are now coming into use. The internal-combustion engine affords expensive but satisfactory power, though in some ways it is not as flexible as an electric motor.

Only narrow, shallow, and unfrozen creek deposits have been dredged up to the present. Deeper deposits

of 60 to 70 ft., frozen in places, are now receiving attention, but as yet there is only one dredge operating successfully under these conditions. There has been little dredging of frozen ground on Seward Peninsula. The working of these deep low-grade frozen deposits will be almost entirely a matter of cheap thawing, and that means a thawing method cheaper than those in use on the Yukon.

The adaptation of the gold-dredge to Seward Peninsula has been most interesting and the dredges are, on the whole, satisfactorily designed.

An interesting feature of the development so far has been the part played by men inexperienced in dredging elsewhere, and this was rather fortunate than otherwise, since they were not handicapped by ideas of practice gained elsewhere under quite different conditions.

In numerous cases the dredges built on Seward Peninsula, after having worked out the gravel or for some other reason, have been moved to another locality. In many cases of this kind the machinery is dismantled, the hull cut into two parts, and the moving done on sleds in winter. Moving a dredge in this way is not difficult.

The past season was shorter than usual, the average period of activity over the entire Peninsula having been

two weeks short on account of a late spring. Operations in some cases, however, were carried on unusually late, even into November.

During the season of 1916 two dredges were built.

The total production of gold from Seward Peninsula, as measured by shipments from Nome, amounted to \$2,833,000, which was 50,000 more than for the season of 1915. The production from dredges remained about the same.

I have made no attempt to state the yardage handled, the cost of operation, or the fuel consumption. The average daily digging capacity of the 2½-ft. boats on Seward Peninsula is between 700 and 1000 cubic yards. The consumption of distillate is probably $\frac{1}{10}$ to $\frac{1}{8}$ of a gallon per hp.-hour.

THE YORK DREDGING Co. finished its ground on Buck creek and is now operating on Grouse creek, into which the former empties. The chief feature of this enterprise is that it mines placer-tin instead of gold, and is, so far as I know, the first adaptation of the placer-dredge to the mining of tin.* The early history of this district is interesting. The miners found that a heavy unknown mineral was choking their sluice-boxes; it was identified by the Geological Survey as cassiterite. It was mined more or less successfully for some time by the ordinary pick-and-shovel and sluice-box method. In 1911 the Union Construction Co. designed and built a dredge for the property. This was strictly pioneering, but the machine has been successful. The dredge has a 2½-ft. open line of buckets, a short screen with 3-inch holes, two flumes and a flat stacker. Each flume is cleaned up in the ordinary way once every 12 hours, the entire feed during this time being diverted to the other flume. The concentrate, in the form of cassiterite, averages 65% tin and varies from fine to lumps of 1½ inch. The concentrate is hauled 14 miles to the beach and is shipped to Singapore for smelting. One hundred and ten tons of concentrate was produced in the three months' season of 1916.

The present depth of dredging is 7 ft., but on Buck creek the usual difficulties of shallow ground were encountered. The dredge has a capacity of about 1000 cu. yd. per day, which is to be increased in the coming season.

THE AMERICAN TIN DREDGING Co. operates a dredge of a design similar to the above, constructed by the American Dredge Building & Construction Co., on Buck creek. The dredge operates in 4-ft. ground and has much trouble in securing the depth of water necessary to float the boat.

THE BERNARD DREDGE, formerly on Anikovich river, but now dismantled, is interesting for the fact that it has been unsuccessful in both its present site and the one from which it was moved, and also for the fact that it was towed from its old site on the beach, four miles east of Nome, some 100 miles on Bering sea to its present

position. This was done without very much difficulty.

THE J. A. WELSCH DREDGE, on Windy creek, finished its ground this season, and may possibly be moved to the Kougarok river north of Arizona creek. This dredge in its operation on Windy creek has had considerable trouble with frozen ground.

THE BEHRING DREDGING Co. has finished its second season on the Kougarok river near Taylor creek. This is a 2½-ft. Union screen-flume dredge and has been successful in its operation.

THE IVER JOHNSON, a 3½-ft. flume-dredge built by the Union Construction Co., will move from the Kougarok river to the Kerwalik river during the winter. This dredge has worked out its ground.

THE ERNST ALASKA DREDGING Co. operates a 2-ft. flume-dredge west of Nome, on what is known as the sand-spit. The dredge was towed last summer to its new site, a distance of two miles from its old position on the east side of Nome. It operated on the east side of Nome for four seasons on a narrow flat extending back a short distance from the beach. It has worked up to the water-line and, on several occasions, has been stranded high and dry by the storms of Bering Sea. To a large extent the dredge has handled material worked by hand in the early days. This operation is the only instance of the successful application of machinery to the present beach-sand.

THE ANDY ANDERSON DREDGE is operating on Center creek at its junction with the Snake river. This is a 3½-ft. dredge, and was moved and re-built by the Union Construction Co., in 1915. It is working a stretch of gravel from the old Center Creek intermediate beach-diggings. There are some, but not many, frozen spots that require thawing. This dredge has been successful.

THE BANGOR DREDGING Co. operates the deepest-digging boat on the Peninsula at the present time. This dredge is a 3½-ft. Californian type, built by the Union Construction Co., in 1914. It was built on 35-ft. ground, but designed to take a digging-ladder extension to work to 50 ft. below the water-level, which it has done this last season. The dredge has a capacity of 1600 to 1700 cu. yd. per day. The gravel contains considerable clay, which interferes with washing and diminishes capacity. This dredge has the only installation of Bolinder engines on the Peninsula; they operate on 'calol' (a special product of Californian oil) and have proved a satisfactory source of power. The consumption of fuel is 195 gal. per day. Assuming a 20-hr. day at full 140 hp., the consumption is at the rate of 0.55 lb. per hp.-hour. The company reports an operating cost, exclusive of interest and depreciation, of 9c. per cu. yd., which is as low a cost as has been obtained on the Peninsula.

THE GUINAN & AMES DREDGING Co. operates a 2-ft. combination screen-flume dredge, built on Glacier creek in 1916 by the Union Construction Co. This is a creek that produced abundantly in the old days of hand-mining, the Utica claim having been worked twice. Besides gold, this dredge is reported to have recovered 400 lb. of scheelite concentrate per week. Scheelite on Glacier

*Dredging for tin is being done by five mining companies in the Malay State of Perak and one in Siam.—EDITOR.

A MODERN ALASKAN DREDGE.

creek caused a good deal of sluice-box trouble during the early days.

THE UPLIFT MINING CO. began operating a new 2-ft. screen-flume dredge built by the Union Construction Co., this year, on Camp creek in the Council district.

THE RUBY DREDGING CO., on the Casa de Paga, did not operate this season, having worked out its ground, but will probably be moved to a new site next season.

THE ALASKA MINES CORPORATION is a re-organization of the E. E. Powell companies, which have operated for a long time near Nome, but not successfully. The old companies have operated the Bourbon and Wonder dredges, the former on Bourbon creek about a mile from Snake river, and the latter on Wonder creek in the vicinity of the Third Beach. The management of the

property is now in the hands of J. H. Miles. A new screen, tables, and distributor will be placed on the Bourbon dredge. The new hull, which was constructed several seasons ago, but which has never had its machinery on board, will receive the 8½-ft. bucket-line and equipment from the Yuba Consolidated Gold Fields dredge No. 6. The steam-turbine power-plant owned by the company and furnishing electricity for the boats, will be thoroughly overhauled, and a good deal of drilling will be done. Thawing experiments will be conducted to demonstrate the best and cheapest method. The old Wonder dredge will be scrapped. It is planned to have everything in operation by July 15. These dredges are in what is called the 'tundra' country between Nome and the Third Beach, and the ground varies

A PIONEER DREDGE, NOW DISCARDED. THE BUCKET-LINE HAS BEEN REMOVED.

from 25 to 60 ft. in depth. It is frozen in spots and the old dredges at times attempted to dig without thawing, which was, of course, unsuccessful.

THE SEWARD DREDGING CO. (formerly the Three Friends Dredging Co.) operates a 5-ft. Californian dredge on Solomon river. This was the first dredge to be operated profitably on the Peninsula, being built in 1905 by W. L. Leland. Recently the company has had a rather checkered career but has continued to operate. In 1914 W. H. Estabrook had a bond-lease on the property and replaced the old steam-plant on the dredge with motors and installed a Diesel generating-plant on the shore. The steam-plant power-cost has always been excessive. The Diesel plant, with the exception of some compressor troubles at the start, has proved satisfactory. The cost of power is 1½c. per kw.-hr. when the dredge is digging 3000 cu. yd. per day. Fuel (equal to 'calol') consumption is approximately 0.45 lb. per hp.-hour. The dredge was not well-adapted to the shallow ground and for other reasons it has never had a high capacity. In 1914, under the superintendence of J. H. Miles, for W. H. Estabrook, the dredge had a capacity of 3000 cu. yd. per day, but I believe that this capacity has not been maintained. During the last two seasons the ground has been exceptionally rich.

THE KIMBALL DREDGE No. 1, constructed by the Flume Dredge Co., was moved during this last winter from Shovel creek to Solomon river. This dredge operated almost five full seasons on Shovel creek and was successful. The new site is on ground previously worked by the original Sievertson dredge, a small oddly-designed machine built for working on the Nome beach in 1900, and later moved to several positions on the Solomon river. The Kimball No. 1 dredge was the first successful flume-type of machine in the Solomon district and did excellent work under severe conditions on Shovel creek.

THE KIMBALL DREDGE No. 2 is working on the Solomon river close to No. 1 on the Gypsy bench some feet higher than the present river. Water is led to the pond by means of a ditch. This is the third season for this dredge.

THE FLOWERS DREDGE, formerly operated by C. Flodin, on Solomon river near Big Hurrah, is to be moved this winter to a new site on Solomon river, a short distance below Oro Fino. This is a Risdon dredge with 2½-ft. buckets and was originally operated by steam-power. Scandia engines, in all probability, will replace steam in the future.

THE GOOSE CREEK DREDGE, operating on Goose creek, a tributary of the Casa de Paga, changed ownership last spring. This was originally a screen-dredge and was changed to the flume type when it was moved to this site two years ago.

THE NOME MONTANA DREDGING CO. has not been operating for the past two seasons. It is reported that this boat will be moved to a new position on the lower Solomon river.

THE MOODY MINING SYNDICATE is operating a flume-dredge formerly owned by C. Flodin on Canon creek, a

tributary of the Casa de Paga. The hull was cut into two parts to facilitate moving.

THE ORO MINING CO. has an interesting equipment on Elkhorn creek, a tributary of the Casa de Paga—interesting from the fact that it is the smallest dredge operating on Seward Peninsula, and during the last season, in proportion to its size, has been the most successful. It has a bucket of 1 cu. ft. capacity and is operated by one 18-hp. distillate-engine. The conditions are ideal for this type of machine.

THE WARM CREEK DREDGING CO. was originally a screen-dredge and not long ago it was changed to the flume type.

THE NORTHERN LIGHT MINING CO. last winter moved its dredge, formerly operated by Lubbe on Mystery creek, to the lower end of Ophir creek.

THE BLUE GOOSE MINING CO. operates a dredge first constructed in 1904. The buckets dump into a flume 20 ft. long that dumps into a screen. In other respects the dredge is of the standard screen-type. It has been reconstructed once or twice, and until this last season has operated on steam, with wood for fuel. During the last season a 120-hp. Scandia engine was used, but not with complete satisfaction. This company has always had high-grade ground and has done unusually well.

THE WILD GOOSE MINING & TRADING CO. operates a standard Californian dredge on Upper Ophir creek. The power is supplied by a distillate-engine. It is reported that the company will provide a hydro-electric plant, taking the water formerly used for hydraulic elevators. This ground is also high-grade and the company has done well.

THE FLUME DREDGE CO. No. 1 dredge is at present operating on Melsing creek. It holds the record, I believe, for the number of moves. It was originally built on Melsing creek in 1910. The hull was cut in two and the dredge moved to Ophir creek. The next move was from Ophir creek to Crooked creek, but in this case the dredge dug its own way. The final move was back again to Melsing creek, but the hull was not moved, since the distance and the price of timber made it inadvisable. This dredge really marked the beginning of the flume-type of dredge on the Peninsula.

The following companies, which with one exception have been operating for several years, worked through the season as usual.

MAX HIRSCHBERG, Sunset creek, north of Teller.

THE DEERING DREDGING CO., Inmachuck river.

HANK FRIES, on the Inmachuck river.

CANDLE CREEK DREDGING CO., on Candle creek.

ARCTIC GOLD DREDGING CO., Frank Middaugh, manager, on Hobson creek.

JULIAN DREDGING CO., E. A. Julian, manager, on Osborne creek.

HASTINGS CREEK GOLD DREDGING CO., now operating a dredge on Hastings creek, formerly operated on Moss gulch.

FLUME DREDGE CO., No. 2, on Melsing creek.

ARCTIC CREEK DREDGING CO., on Arctic creek, Nome.

Geology of the Bawdwin Mines

By M. H. Loveman

INTRODUCTION. *Bawdwin is in the State of Tawng Peng, one of the units that constitute the Northern Shan States. It is under British rule and is generally considered as part of Burma.

The orebodies here described have been re-discovered and developed within the last three years. When mining first began at Bawdwin is not known, but it must have been as early as the beginning of the 15th century, as indicated by Chinese inscriptions. The mines were aban-

and quartzite. There are also extensive granitic intrusions of undetermined age. The metamorphic rocks are followed unconformably by Ordovician sediments, and the schist is therefore either Cambrian or pre-Cambrian. Silurian sandstone, in places, is found resting directly upon the unfossiliferous series. At a few

doned by the Chinese about 1868, probably because of the great increase in the volume of water appearing in the workings. During the long occupation of the Chinese they performed an immense amount of work, having removed more than 1,000,000 tons of rock. The attention of Europeans was first directed to the mines by the big slag-dumps. When the slag was removed, work was commenced on the orebodies, but as the old workings were filled with water the progress made at first was slow and dangerous.

GENERAL GEOLOGY. The rocks of Tawng Peng are all of the pre-Cambrian and Paleozoic eras. The west and central portions of the State are mainly composed of mica-schist, and of much-folded unfossiliferous shale

*Abstract Trans. A. I. M. E., New York meeting, February 1917.

places along the border of the pre-Ordovician rocks are small exposures of rhyolite, tuff, breccia, and flows. The most important of these is the rhyolite at Bawdwin.

In the vicinity of the mine are narrow valleys amid precipitous hills, which rise more than 2000 ft. above the valley-floor. The hills are destitute of timber, the trees having been removed years ago for fuel, and 50 years of idleness has not resulted in re-forestation.

The rocks at Bawdwin are first, the rhyolite tuff, breccia and flows; second, the overlying and underlying non-fossiliferous sedimentaries. No limestone has been found in the sediments. The sandstone is red to gray, with small irregular quartz grains cemented by sericite.

The shale is light-gray to purplish in color and is compact, the original laminations being almost wholly destroyed.

The rhyolite forms a northwest-southeast band of irregular outline with many offshoots, some of which are connected directly with the main mass, and in some instances disconnected, occurring as separate outcrops in the sediments. The general outcrop of the rhyolite indicates the axis of the anticline, which plunges both north and south. This anticline is the principal one of a series of folds that parallel the rhyolite. Almost the entire exposure of the rhyolite is tuffaceous, with local areas where it includes numerous fragments constituting a breccia. Away from the zone of mineralization the rhyolite is a hard dense rock, with many phenocrysts of quartz and feldspar. These sometimes, particularly in the case of the feldspar, attain dimensions of an inch or more. Where alteration has been pronounced the feldspar has changed to sericite, though in the orebody the alteration is more complete, and the feldspars are largely metamorphosed to kaolin. Generally the outline of the crystals has been obliterated. There are occasional traces of a ferro-magnesian mineral, probably amphibole. Zircon, apatite, and tourmaline are present in small amount. The rock of the ore-channel has been entirely transformed by crushing, leaching, and silicification.

THE ORE-ZONE. The orebodies occur in a zone 300 to 1000 ft. wide in the rhyolite-tuff. The boundary of the zone is not sharply defined, mineralization near the borders gradually becoming less until it ceases entirely. In the south-western part of the rhyolitic area the tuffaceous character of the rock is more pronounced, and it is through this that the zone of mineralization extends, passing beyond into the harder finer-textured rhyolite that makes up the greater part of the rhyolitic area, though in this harder rock mineralization is much less pronounced.

The rock of the ore-zone varies from fine-textured silicified tuff to a rock composed chiefly of the included fragments of other rocks. Large kaolinized feldspars are characteristic of the big orebodies. The principal feature appears to be a silicification that has replaced practically all of the original constituents of the rock. In the ore-channel the rock is a mixture of quartz, sericite, chlorite, and kaolin, with some calcite.

THE OREBODIES. The valuable metals are zinc, as sphalerite; lead, as galena; copper, as chalcopyrite; and silver, the manner of occurrence of which has not been determined, though it appears to be directly associated with the galena. The ore occurs in solid sulphide masses with but little gangue; as veins; as reticulated seams, forming a stockwork; and as an impregnation of the rock-mass. The principal orebody, called the Chinaman Lode, is 1200 ft. long and from a few feet to more than 100 ft. wide. It is a zinc-lead-silver orebody, with a small quantity of copper along the edges. The largest single body of copper ore is found on the 300-ft. level, north of the Chinaman Lode. It is 130 ft. long with an

average width of 30 ft., running 14% copper, 7 oz. silver, and a small percentage of lead and zinc on that level. About 75 ft. higher it passes into zinc-lead ore, and does the same 30 ft. below the 300-ft. level. This orebody is thought to be the northern extension of the Chinaman Lode, beyond its interruption by a fault.

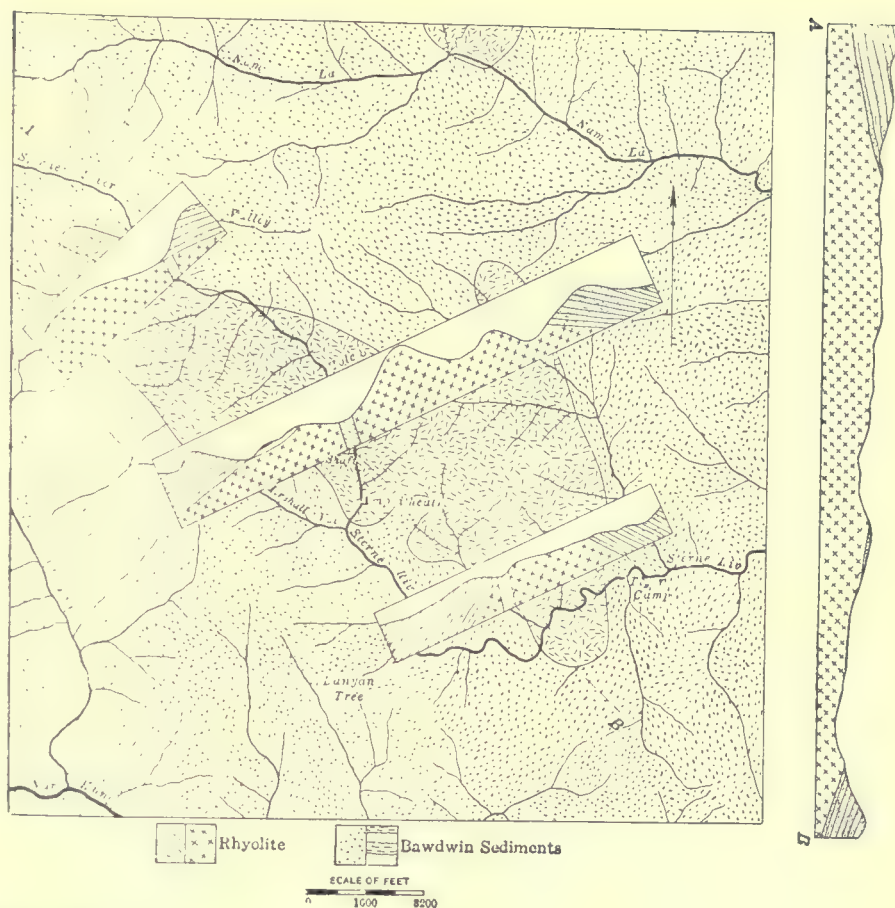

A cross-section through the Chinaman Lode shows a central core of solid zinc-lead sulphide, the zinc generally predominating. On both sides of this central core are alternating bands of heavily mineralized tuff and solid ore. These, in a general way, parallel the central portion in both strike and dip, but they pinch out, coalesce, and are otherwise irregular. The bands are higher in lead than in zinc. Usually copper is found along the edges, and occasional seams and bunches of ore are found at some distance from the main orebody. Pyrite is found to a limited extent in the main orebody, but in greater amount near the edges. The central core of the Chinaman Lode is solid ore as much as 80 ft. thick; on some levels it maintains an average width of 55 ft. for 800 ft. in length, and of 50 ft. for an additional 200 ft. One block, 800 ft. long, 600 ft. high, and 30 ft. wide contains 1,750,000 tons of ore, with an average of 30 oz. silver per ton, 31% lead, and 29% zinc. This block is over 75% solid sulphides of lead and zinc. The mass has a high west dip in the upper levels, turning over gradually with increasing depth, until it dips steeply eastward. It thins out gradually on approaching the sedimentary rock.

Owing to the work done by the early miners, the condition and shape of the orebody near the top is concealed, but it appears to thin out in the approach to surface. The outcrop is comparatively small and inconspicuous. At several places sphalerite and galena are found in the outcrop, but generally the surficial ore has been oxidized and leached, the outcrop being indicated by a broad zone of soft decomposed rock colored by iron oxide, copper carbonate, and lead ore. This gossan runs 3 to 4 oz. silver and 5% lead per ton. It is quarried at one place for silicious flux. The depth of the gossan varies from place to place, but is rarely more than 50 ft. It is succeeded generally by a zone carrying secondary copper sulphide, principally chalcocite with some bornite. Where the zinc and lead sulphides appear at the surface it continues to the greatest depth thus far reached in the mine, 725 ft., with no change in character. The lead-zinc ore is an intimate mixture of galena and sphalerite, the galena forming around grains of sphalerite, and as thin filaments through the blende. The ore grades off in both directions—toward the zinc end to a solid mass of soft sphalerite, and toward the lead end to pure coarsely-cubical galena.

The silver content varies with that of the lead and independent of the zinc, indicating that the silver is associated with the lead. The presence of copper, even in small amount, destroys the silver-lead ratio, as the copper in the small veins adjoining the main orebody is often high in silver. Ordinarily one ounce of silver accompanies 1% of lead.

THE FAULTING with which the mineralization is associated was not confined to a single plane, but occupies a zone in places 1000 ft. wide. Along this zone a multitude of fractures of varying strike and dip were developed. As a system it is complicated, and a majority of the faults can be traced a short distance only. The displacement in most instances has been slight, often scarcely noticeable. However, a few dominant faults that can be traced a long way have been accompanied by considerable displacement. One such fault cuts off the Chinaman orebody at its southern end, for beyond it no ore has been discovered.

The faults, as a rule, are accompanied by soft gouge and rounded fragments of rock. The gouge is often colored black by minute particles of sulphide. Generally the faults appear to be later than the mineralization, and it is probable that some of the orebodies branching off from the main Chinaman

Lode may lie along fault-planes. In the big orebody the complete replacement of rock by sulphide has obliterated the original character of the ground, so that the ore now represents a replacement of the original rock in a widely fractured and crushed zone rather than one that has spread out into the walls from a central fault-plane.

THE GROUND-WATER level is close to the surface. The ore-channel strikes diagonally across the trend of the ridges, so that the ground-water was tapped by the drainage adits only a few feet from the valley-bottoms. There did not, however, appear to be a saturated zone below the water-level. Diamond-drill holes at a greater depth than any of the workings occasionally go completely dry, and water pumped into them disappears. This experience was noted even in cases where the holes were cemented all the way down. The great number of old workings and the numerous fault-planes tend to obscure the natural underground circulation. A heavy rainfall has an almost immediate effect on the amount of water in

the upper levels, and a portion of the surface-water probably drains along faults to the lowest levels.

It does not appear that changes of great magnitude have occurred in the condition of the orebodies since their original formation. There is no distinct zone of secondary enrichment—barring the small amounts of chalcocite—as is indicated by the silver content, which shows no marked change from the upper part of the orebodies to the lowest openings, several hundred feet below the water-level. There is a gradual increase of silver in descending, but this is due to a corresponding increase in lead. The zinc also increases slightly, but this may be attributed to the almost entire disappearance of gangue-minerals and of low-grade patches in the solid core.

Using a Fumerole to Get Steam

An ingenious Italian civil engineer has been successful in employing the heat of a fumerole near Volterra, in Tuscany, to develop 15,000 horse-power. In that district are numerous fissures in the ground from which a large and constant volume of steam escapes violently into the air. The steam contains several minerals in solution, of which boric acid is the most valuable, and this is saved and utilized in the manufacture of borax. The heat of these steam-vents has long been used in warming the dwellings near-by, but until recently only a small part of the steam available has been utilized. In 1903 the first attempt was made to employ the heat of the steam-vents as a source of power. A strong jet of the escaping steam was applied to a small rotary-motor, and this experiment resulting in some success, the steam was conducted to a small reciprocating-engine that was used to run a dynamo, generating enough electricity to light a part of the borax works. These applications proving satisfactory, an effort was made to make available a larger volume of steam by boring holes in the ground. These bore-holes were driven to a depth of from 300 to 500 ft. and were lined with iron pipe. The holes are from 12 to 20 in. diam. The steam issues under a pressure varying from 30 to 150 lb. per square inch, and the temperature is said to range from 300° to 375°F. For years the steam-jets have not diminished their activity, nor is there any decrease in the volume of steam or the pressure when additional holes are bored so long as they are not less than 50 ft. apart. It has been demonstrated that each hole will supply steam at a temperature of 300°F. with the equivalent of 1000 to 2000 theoretical horse-power per hour. The result of the early experiments has been followed up, and in 1906 the steam was applied to a 40-hp. engine with satisfactory results, as far as the generation of power was concerned, but the minerals in solution and the sulphuric acid in the steam had such a corrosive effect on the cylinder of the engine that frequent repairs were necessary. The introduction of the steam directly to the engine was discontinued and it was transferred to the boiler, using the heat of the steam, instead of fuel in the

usual way, to raise the temperature of the water in the boiler, and producing a pressure in the boiler of about 30 lb. per sq. in. This boiler-steam was then passed through a super-heater and used to drive a 300-hp. condensing steam-turbine direct-connected to a three-phase generator, which supplied power and light to the works, and to the neighboring villages. This installation was so satisfactory that when coal became scarce and very expensive soon after the beginning of the War, the possibility of employing the steam-vents on a still larger scale was considered seriously. Three sets of condensing turbo-alternators were put in place, each of 3000 kw., operated with super-heated steam at 22½ lb. pressure that was generated in specially constructed tubular boilers of the marine type, and provided with aluminum tubes to resist the corrosive action of the acid. The steam used in driving the turbines is generated from water fed into the boilers, heat being supplied by steam from the vents. The boiler-steam is passed through aluminum pipes arranged between the boilers and the turbines. On its way the temperature is raised to about 300°F. by super-heated steam from the vents. The condensed steam from the turbines is returned to the boilers, and no natural steam comes in contact with the engines, thus obviating the corrosion of metal that had been the principal difficulty to overcome.

The success of this novel utilization of a natural source of heat and power suggests the possibility of its application in other regions where similar conditions exist. In California, near Mount Lassen, are numerous fumeroles and steam-vents, particularly in Hot Spring valley, and some application of the energy going to waste there possibly might be made in a manner similar to that adopted in Italy. On the Darragh ranch in Big Smoky valley, Nye county, Nevada, there is a large boiling spring, the temperature of which is stated to be 242°F., or 30° hotter than boiling water. Obviously, it is a possible source of power, but the water is utilized only by directing the stream into a cemented basin in a bath-house. Steamboat Springs, Nevada, near Carson City, is another noted fumerole, but no use whatever has been made of this possible source of power. At Ouray, Colorado, are hot springs, the water of which is used in bath-houses and in a few instances to warm dwellings, yet the heat from this highly heated water is sufficient to give a comfortable temperature when desired to every house in the town. It is merely one of many instances of neglect to take advantage of natural resources.

MAGNESITE analysis is always stated in terms of magnesia (magnesium oxide), carbon di-oxide, and such impurities as may be present, for example, silica, iron oxide, calcium oxide, and aluminum oxide. The magnesium, as metal, is never given in the usual certificate of analysis of magnesite. Magnesite, also known as periclase, is the natural oxide of magnesium, and consists of magnesium 60%, oxygen 40%. The mineral usually is found in small disseminated grains in some limestone and occasionally with deposits of magnesite.

Design and Operation of Motor Trucks

*At first the design of the motor truck followed closely that of the pleasure-car. This was a natural sequence for a business growing up as a branch of pleasure-car manufacturing. The same type of engine was used for both and the same drive through a differential on a live rear-axle, such as is still in use for trucks of the light-delivery type. For the heavier trucks the frame of the car was lengthened, and the differential and rear-axle gave way to a differential and jackshaft attached to the frame. The jackshaft carried sprockets, and the final drive was made by a chain to the rear wheels, which were carried on a dead axle. This arrangement had three obvious advantages: first, it kept the engine-drive as small and light as possible, since the final reduction in rotations was made at the rear wheels; second, it was accessible, and the gear-ratio could be changed at will by putting a different-size sprocket on the jackshaft; lastly, it segregated the power-plant so that the truck might be considered as composed of two separate units. The first of these units, the wheels, axles and steering-gear, was expected to take the jar and distortion of running, while the other unit, the truck-frame and power-plant, floated above the first one on the springs, the chain furnishing the power connection between the two units. Automobile engineers state that each pound of 'unsprung' weight is as hard on the tires, and therefore on the truck, as four pounds would be if placed above the springs, where the effects of the weight are cushioned. The chain-drive kept the weight of the parts a minimum, and also kept it above the springs.

It was soon discovered that it was not possible to absorb all of the vibration and twisting which hard service gives to a truck without transmitting a considerable part to the frame and power-plant. To the jar from the road was also added the twistings set up in the frame because of eccentric loading. These effects were all transmitted to the power-plant, to the radiator, and to all parts which were attached rigidly to the frame. There were two possible ways of dealing with this difficulty; first, a more rigid frame and a better cushioning through the tires and springs; or, second, a flexible frame to which the various power-plant units would be flexibly mounted, so that each unit, while in itself a compact, rigid, perfectly aligned machine, would not suffer distortion by twisting set up in the frame. These units would be connected by shafts having universal joints or some other flexible connection. The modern truck has been developed along both of these lines. For the lighter and faster-running

delivery truck the pneumatic tire is largely used, and its use is being extended to heavier trucks. Double pneumatic tires for the rear wheels are used sometimes, and single tires are being made up to 12 in. tread diameter. Both pneumatic and solid tires have been made as elastic as possible without too great a sacrifice of other desirable qualities. Truck springs have been greatly improved also. The older types of truck springs were made up of rather thick leaves. They were short and narrow and had considerable camber. With the advent of modern heat-treated steel a much better design of spring with thinner leaves has been developed. It is longer, flatter, and better suited to the needs of the truck. Such springs are made of high-grade carbon or alloy steel, with the leaves self-lubricated and the spring-eyes provided with phosphor-bronze bushings. The pins are nickel steel and the clips are chrome-nickel or vanadium steel. The old-fashioned full-elliptical type has given place to the semi-elliptical as the preferred type. This improvement in the design and quality of springs and tires has reduced considerably the strains in the frame.

In the smaller trucks, up to about two tons capacity, it is possible to combine the engine, the flywheel and its clutch, and the transmission in one rigid assembly. This gives perfect alignment. This unit power-plant is then flexibly mounted within the main frame, usually with three points of support, two attached rigidly to the main frame and the third swiveled from a bearing on a main-frame cross-member. Another method is to mount the power-plant rigidly to a sub-frame, which, in turn, is flexibly mounted within the main frame. This mounting may be a three-point support or one of four points, with spring-buffers to absorb the jar and twist. Where the transmission is separate from the engine it is also flexibly mounted to the frame. The differential and jackshaft-unit is treated the same way.

MOTOR-TRUCK ENGINES. Motor-truck engines do not differ greatly from those on pleasure-cars. Motor-truck service is more severe and the engines are kept at capacity for longer times. For this reason the engines are run at slower speeds, from 800 to 1200 r.p.m. for trucks of one ton capacity or heavier, and the engines are therefore larger for the same horse-power. In general, truck-engines are usually built stockier, with heavier crankshafts and connecting rods and larger bearings throughout. The water-jacket space is somewhat larger and the cylinder-walls thicker, which permits more re-boring. The radiator is larger than for the same size of pleasure-car engine. The valves, carburetor, and intake-manifold are often made smaller than on a pleasure car. This is possible with the slower speed, and has the advantage of preventing the driver

*Abstract of paper presented at a meeting of the Los Angeles Section of the American Society of Mechanical Engineers, by W. H. Clapp.

from over-speeding the engine when it is not under governor control. Governors are now coming into general use, however, on trucks of one ton capacity or heavier. The governor throttles the gas mixture between the carburetor and the intake-manifold. It may be driven from any exposed rotating part of the engine, or from the transmission, or from the wheel of the truck itself. The four-cylinder, four-stroke-cycle engine is now standard for truck construction and is used on 95% of the trucks manufactured. There are a few makes of two-cylinder engines with the cylinders opposed to each other. One or two builders have recently brought out six-cylinder engines, but their use for most work would not seem to be warranted at the present price of motor fuel. The four-stroke cycle is made necessary by the varying load which every truck engine must handle.

Cylinders are cast separate, in pairs, or *en bloc*. The preference seems to be for cylinders in pairs with either three or five crankshaft bearings for trucks of moderate to large size, and cylinders *en bloc* with three bearings for the smaller sizes. Individual cylinders are used on many of the larger trucks. As to the placing of valves in the cylinder, the same types obtain as on pleasure-cars. There is a preference for the 'L-head' type for the smaller engines up to about four inches in diameter, as ample valves may be used and still provide for the necessary water-cooling space around them. Nearly 80% of all engines are of this type. With increase of cylinder diameter, cooling is more difficult, and many makers prefer the 'T-head' construction with valves on opposite sides of the cylinder. There are a few motors with the valves in the head, and some with one set of valves in the head and the other in the side. The bore-stroke ratio varies from 1:1.1 up to 1:1.5. Average sizes vary from 3½ by 4¾ in. for a 1-ton truck up to 5 by 6 in. for a 7½-ton machine.

The clutch is usually housed with the fly-wheel. The cone-clutch with leather against metal and the cone a part of the fly-wheel itself has been the favorite until recently. The more complex multiple-disk clutches with steel against steel or against bronze plates running in an oil bath, or steel against a built-up fabric of brass wire and asbestos running either in oil or running dry are also largely used. The dry type has been gaining in favor. It is accessible and there is abundant surface to take care of starting-friction.

TRANSMISSION SYSTEM. There are a few friction-type or planetary-type transmissions on some of the lighter trucks, but the selective type with sliding gears, three speeds forward and a reverse, is generally used. It has not been entirely successful for heavy truck duty. The operation of a transmission requires a certain amount of skill and respect for machinery not always found in an unskilled employee. There has been a marked tendency to adopt some form of individual clutch system for the heavier trucks. Also a fourth speed forward on these trucks is coming into use to

meet the requirements of tractor duty and of starting under heavy load.

There are two methods of water cooling used on light-truck engines, one the thermo-syphon, for which the claim is made that it is simple and effective, while opposed to the cheaper and simpler method is that of pump circulation, which tends to keep the engine cylinder more nearly uniform in temperature under all running conditions. Other examples of different design for truck parts are the frame members, which may be built-up shapes of channels or I-beams, or pressed-steel frames, which are lighter and more flexible, made of a higher grade of heat-treated steel, more expensive, but coming into increased favor with truck manufacturers. Again, the truck wheels may be of the wooden artillery-type, of cast-steel, or of built-up pressed-steel construction. For bearings, flexible rollers and balls compete with the truncated cone-roller. Brakes are either shoe or band, each of which may be either internally expanding or externally contracting. They may be placed both on the rear wheels, or one set, usually the service brakes, on the jackshaft on chain-drive machines or on the main shaft back of the transmission on the other types of drives. Again, there are four types of radiator construction, twenty standard types of carburetor, and nearly as many ignition systems. Lubrication may be by splash, by forced feed, or a combination of both, and so with nearly every feature of truck construction.

TYPES OF FINAL DRIVE. For light-running trucks the pleasure-car type of drive with the differential on the rear axle is customary. Its use is restricted to cars of 1500-lb. capacity or less, as a greater gear-reduction than about five to one gives such a large differential assembly that there is not enough road clearance. An additional speed-reduction of some kind must be made for the heavier trucks. The many advantages of the chain drive have not been sufficient to overcome the objectionable features of exposed grit-collecting parts and broken chains. Three separate types have been developed to meet these objections.

The first of these types, the double-reduction axle, uses one pair of bevel-gears and one pair of spur-gears trained together and housed with the differential on the rear axle. There is the advantage of enclosure of all working parts, quiet operation and no thrust loads on the differential. The assembly is heavy and there are a good many parts. Its use is now restricted to a few makes of light trucks of 1½ tons capacity or less.

The internal-gear drive is also a double-reduction drive, as two sets of gears are used. It is also like the chain drive, in that a dead axle carries the load while the differential is on a jackshaft, but in this drive the jackshaft is carried alongside of and parallel to the rear axle, while the chain connection gives way to a spur-pinion running inside an annular gear on the rear wheels. It is quiet in operation and the parts are all enclosed. It has the advantage of a dead axle to carry the load, an argument that appeals to many customers;

also the differential is smaller than that on the double-reduction drive, as it runs faster. There is, however, a thrust on the differential from the driving shaft. The weight-carrying axle is usually of I-beam construction, and the jackshaft may lie either in front of or back of this axle. This drive was first developed in Europe, and has been used increasingly in this country, principally for trucks of from $1\frac{1}{2}$ to 3 tons capacity.

The worm-gear drive, while it has met with much opposition, is the simplest and possibly the most satisfactory of the three types. It has fewer parts, since the differential is carried within the worm-wheel and the entire reduction is made in one step. There is a live rear axle which transmits the power to the rear wheels. This is usually of the full floating type, with the truck weight carried on the outside of the axle casing. The live axle must be large, as must also be the differential, since there is no reduction in rotations at the wheel. There is a heavy pressure between the worm and wheel, as the wheel is of small diameter. It is necessary to maintain exact alignment between the worm and wheel. This requires a heavy built-up housing to carry the assembly. This housing is of cast construction. All of this weight comes on the tires with no spring intervening. In spite of these objections, the worm drive is now being used on all sizes of trucks from $\frac{1}{2}$ up to 6 tons capacity. The success of the worm drive depends upon exact proportions, perfect alignment at all times, and, most important of all, the maintenance of an oil film which will not be squeezed out by the thrust of the worm-shaft.

There are a variety of four-wheel drives on the market in which various combinations of internal gears or live axles are used to propel the truck through all four wheels. As the front wheels must swivel, and in some cases the rear wheels also are used in steering, it is necessary to provide for this in the drive either by knuckle-joints or through a bevel-gear train with one gear mounted on the swiveling axis. These trucks are much used where the road conditions are severe, as for ore-hauling work in mountainous country or out on the desert, and for army-transport work.

What has been said of the methods of driving gasoline-trucks applies also to battery-driven electric trucks. These trucks, because of their simplicity and durability, and because of a high starting-torque compared with the gasoline truck, are much used for work within their special fields. They are specially suited for delivery service in congested districts and where the number of stops per mile is large, and for special service such as street-work hauling with heavy loads and many stops, drawing conduit wires, raising telephone poles, and wholesale delivery. Their use within these fields would be increased if the first cost were not so high. It is considerably more for the lighter types of truck. Electric trucks are handicapped by a slower speed, about 60% of that of a gasoline truck, and the mileage is limited to between 35 and 45 miles per day as compared with 75 miles or more for the latter. Also,

the electric truck must be brought to a point where direct current is available for charging the batteries. For work for which they are suited, the electric trucks will usually show a lower daily cost than gasoline trucks, where the latter are held down to the same number of miles a day. It frequently happens that it is not possible to get a greater mileage with the gasoline truck because of frequent stops and congested streets. The electric truck, with fewer parts, and none of these reciprocating, gives a lower maintenance cost outside of batteries, and the depreciation has been less than on the older types of gasoline trucks.

There is another type of truck which combines both the gasoline-engine and the electric-motor drive. The engine runs at a constant speed at all times, and is direct-connected to a generator which drives motors placed within the four built-up steel wheels of the truck. Each motor is carried by a steering knuckle, and the armature has a pinion at one end which engages with a ring gear on one side of the wheel, while a pinion on the opposite end of the armature engages with another gear on the opposite face of the wheel. This arrangement, while undoubtedly less efficient than the direct-connected drive, has all of the simplicity of the electric truck, for it eliminates all chains, sprockets, clutches, sliding gears and differential. The mileage is unlimited, and it promises to meet the requirements of heavy duty and long-drawn-out service.

For every truck it is necessary to provide some means of resisting the rear-axle torque, which reacts on the driving gear and axle casing. The reduction gear on the rear axle tends to rotate instead of turning the wheel, and carries the axle casing with it. This turning must be prevented by some member connecting the casing with the main frame of the truck. Again, the thrust of the wheels against the roadbed must be made to react on the frame of the truck instead of upon the axle bearings alone, for the frame is suspended on the springs above the axles. There are several ways of taking care of these two forces. The torque may be taken through the rear springs or through separate torque-rods swiveled from the rear-axle housing to the frame. The thrust may be transmitted through the rear springs, or through radius-rods, and these rods may take both thrust and torque, or there may be separate rods for each duty. Where the springs take the thrust they are shackled at the rear end only, and the front end is pin-connected direct to the frame. A combined torque and radius-rod is frequently used for the internal-gear drive axle, and for many of the smaller worm-drive trucks. The larger worm-drive trucks use separate torque and thrust-rods.

The demand for a light truck has been met by making a vehicle which is much lighter for the rated load than the heavier trucks. This is possible because of the higher engine-speed, a more simple final drive, torque and thrust taken through the vehicle springs, and by the generous use of special alloys and heat-treated steels. These trucks are too light for the load

that they are rated to carry as is shown by records, which show that the average life of a light delivery-truck is 35,000 miles, whereas the heavier trucks when properly driven and maintained can be depended upon to give 80,000 to 100,000 miles, or even more for the better grade of trucks. It would seem that there is a real field for a serviceable light truck which will at a little greater cost give enough lower depreciation and maintenance to be a profitable investment.

In California, distillate is being used to quite an extent as a substitute for gasoline. The cost per gallon is about half that of gasoline at the present time, and the B.t.u. content somewhat greater. A local truck-manufacturer has been very successful in equipping trucks with gasifiers by which the heat of the exhaust gases from the engine is used to heat the inlet air as it goes to the carburetor, and also to heat the mixture as it goes from the carburetor to the cylinder. A supply of gasoline is carried and used in starting. The consumption of distillate is about the same as that of gasoline. The success which has attended this innovation would seem to justify the claims of the manufacturer that the use of distillate does not increase carbon trouble. The matter of a lessened volumetric efficiency is negligible.

Tires will outwear the manufacturers' guarantee at least 25% when used on good roads. Overloading and over-speeding are the things that shorten tire life. However, the important consideration is not tire-economy, but economy of truck operation per ton of material carried; therefore, durability is only one factor that must be taken into account. Resilience, which prevents the wasting of truck power; cushioning-effect, which keeps the maintenance charges low on the whole truck; a good tractive grip, and a reasonable cost are all properties which are required in a truck tire.

OPERATING COSTS. In discussing motor-truck costs it is not possible to neglect the human factor, which here more than in most cases of machinery-handling is one of the principal items. It is hardly too much to say that maintenance costs are chiefly driver. An expensive and intricate machine is put in charge of a low-paid employee who is not the owner and who ordinarily has but a limited knowledge of machinery. This is one reason why the life of a light truck is usually about two or three years.

It is impossible for the manufacturer to devise a shop test that will equal the brutality of actual service. The modern motor truck has had to meet the demand for a vehicle that will stand abuse. The careless or indifferent driver is quick to find this out. Operating costs for the same make and capacity of truck engaged in exactly the same kind of work for one firm will frequently show a variation of 40% in the items of gasoline, oil, tires, and maintenance. It is easy to see how a poor driver will shorten the life of a truck.

Manufacturers have tried to meet this condition by making truck parts as few and simple as possible; by standardization of parts; by making wrong assemblies

impossible; by printing detailed information about oiling and caring for the truck; and by instituting a follow-up service to get the truck owner started right. The truck-governor has helped to solve the speeding problem. Another aid is a recording speedometer, which gives a graphical log of each day's run—velocity plotted against time; thus every minute of the day is accounted for; the number of stops and time of each, maximum speed, etc.

Lubrication is probably the most important item in truck maintenance. Manufacturers have tried to make oiling simple and easy to do by making oiling places few and accessible, and by providing charts and printed instructions for this work; some parts every day, some parts twice a week, etc. Still, there are about seventy places in the average truck that must be lubricated, and if there is no intelligent head to look after this work, local wear soon starts and depreciation is rapid. Motor oil should be changed frequently, at least once for every 1000 to 1500 miles' run. It is not enough to build up the supply, as the oil becomes mixed with carbon and with grit from the intake air and soon loses its lubricating qualities.

In deciding upon a truck, one of the most important questions to settle is that of size. On good roads it is better to buy a truck too small for the work than to buy one that is too large. A 5-ton truck costs 25% more to operate than a 3-ton machine, nor is this cost much reduced by taking a lighter load on the heavier truck. Interest, depreciation, maintenance, taxes, insurance and fuel—all are higher.

Another point that must not be overlooked is that the capacity of a truck is figured for average conditions. A half load on a truck carried over a road full of ruts and chuck-holes is much worse for the truck than a 20% overload on a good concrete or asphalt road. A 6½-ton truck recently carried an 11-ton casting up the Mount Wilson toll road, a distance of 9 miles. This is a tremendous overload, but it can not be said that the truck was injured by it. In fact, it is probable that the truck parts were not weakened, for the road, while steep, is firm and smooth. I do not wish to encourage overloading, which has been responsible for many truck failures, but I do wish to point out that an occasional overload of 25% or even 50% when handled carefully on a good road is not objectionable, while to haul a heavy truck day after day, loaded at half capacity, is a serious matter if one would haul cheaply.

It is possible to buy a truck that is suited for work on good roads or one that is especially designed for rough roads, mud, steep hills, and severe service generally. The problem is to know what is suitable and to weigh properly the arguments of the salesman who offers a 2-ton truck with a 15-hp. motor and a 25-hp. rear axle, and the counter arguments of his rival whose truck has a 25-hp. motor and a 20-hp. rear axle. This is one of the surprising results of the modern method of making a truck from assembled parts, and while for some particular service, there may be advantages of

such variations in the relative strength of truck parts, it is a fact that both extremes are being sold for exactly the same work. The Society of Automobile Engineers has done an important service in standardizing the parts for auto trucks.

METHODS OF REDUCING TRUCKING COSTS. To get a low cost per ton-mile, it is necessary to keep the truck moving. Devices which cut down the time of loading and unloading are important. Among these are self-dumping bodies for various kinds of stone, hot asphalt or lumber; loading-chutes on bins which are filled by elevator or conveyor; there is also a movable steel-tipple which can be run alongside a train of flat-cars and be filled by shovelers while the truck is on the road, so

FIG. 1. COMPARISON OF COSTS FOR 5-TON GASOLINE TRUCKS AND HEAVY TEAMS.

that the actual time required to fill the truck is small. Another device is the use of extra truck bodies, which are loaded while the truck is on the road and swung on the truck by an air-lift or other hoist. In interurban-delivery service, loading-nests or cartridges are being used. These are filled in the store and run on the truck. There is some promise in the extension of this device for relieving the congestion around freight stations and also for interurban service where a heavy truck can bring all of the orders for an entire community and local deliveries be handled by light trucks each with its special cartridge.

Fig. 1 gives a comparison between the cost of operating a 5-ton gasoline-truck and heavy teams for such work as rock and dirt hauling and heavy transfer work generally. The costs are figured from actual experience based on a maximum of service per day and from an assumption as to what the costs would be if the vehicle did no work. The curves show that the truck should have enough work to do to occupy the time of more than one team, if it is to be the cheaper vehicle. The Pacific Electric Railway Co. uses heavy trucks for patching the paving along the line. They find that for work outside the business district the truck will do the work of two to three teams, depending upon the length of haul and the size of the job; for long-distance hauling the truck will do the work of four or five teams.

In paving Vernon avenue the rock and crushed stone were delivered by teams, the average haul being about two miles. Each team delivered a 3-ton load and averaged $5\frac{1}{2}$ trips per day. When work on other contracts took the teams away, the work was sublet to another contractor who took the job at the same price per ton as the teams were figured to have cost. Three 5-ton trucks averaged 12 trips per day each, and carried an average of 54.7 tons per day apiece. This makes each truck equivalent to 3.3 teams, which would represent a considerable saving by the use of trucks, provided they could be kept steadily employed.

Barring-Down

The following, by William McCarthy, of the West Colusa mine, at Butte, Montana, is from *The Ingot*, for November, 1916, and is so full of sensible suggestions that it is a pleasure to re-print it:

"When barring-down, especially in a stope where there is a lot of bar work to be done, it is a good idea to first see that your floor is good, and clean. See that there are no tools of any description or loose lagging for you to trip and fall over. You may have to make a quick jump backward or sideways to avoid a falling rock, for one can never tell which way a rock is going to bounce when it hits a cap or girt.

"Watch your bar, for it is surprising the way a rock will slide down a bar and give you a cut or bruise; and often you may get a whole lot more than you really expect.

"Never stand behind a man using a bar, but if possible stand where you can watch the ground, for you may notice a seam or crack open up that he has failed to see.

"Try to avoid barring over a cap or girt, for a rock may strike the end of the bar and a broken arm or jaw-bone may be the result."

To the above we may add: never bar-down with a bar so short that the end does not pass your side, for barring-down with a short bar—one that when reaching up, brings the lower end directly in line with your body, introduces an element of great danger that with a longer bar may be obviated.

DE-TINNING of scrap tin-sheet, old tin cans, and other articles of tinned sheet-iron is about to become an important industry at Birmingham, England, where a corporation has been organized to undertake this business. This industry had reached importance in Germany before the War. In the United States every large city could supply enough old tinned material to justify a plant for the recovery of the tin. The cost of the Birmingham plant for de-tinning scrap-tin will cost \$15,000.

AMALGAMATING-PLATES are said to be discolored by black oxide of manganese. A solution of 16 oz. hydrochloric acid in 5 gal. of water will remove the objectionable film, but it requires vigorous scouring with a brush or piece of gunny-sack to accomplish the desired result.

Influence of Silver on Gold Recovery From Sulpho-Telluride Ore

*A recent report by the metallurgical staff of the Great Boulder Perseverance mine at Kalgoorlie contained the following interesting note:

The residue averaging 0.742 dwt. (74.2 cents) is above normal. Treatment conditions were good throughout the month. Roasting was better than the standard required (that is, 8 cc. $\frac{N}{10}$ iodine reducing value per 100 grams of ore), and in ordinary circumstances should have resulted in residue valued at 0.54 dwt. per ton. During the early portion of the period \$5.43 gold and 3.3 dwt. silver; and the residue 60.8c. gold and 1.74 dwt. silver. From the 10th there was a rapid rise in the heads, also in the residue. The roasting-furnaces were working with normal load, giving an average roast of 6.8 cc. $\frac{N}{10}$ iodine; without alteration of feed to the roasters the iodine test rose to 10 cc. for two days, the feed was then reduced by 100 tons per day until 6 cc. $\frac{N}{10}$ iodine and under was the daily average roast. The residue, however, did not return to normal, and for the remainder of the month averaged 80.9c. gold and 3.05 dwt. silver, the ore assaying \$6.74 gold and 8.04 dwt. silver. The reduction of feed to the roasters, higher strength of cyanide solution, and increased alkali, with longer period of agitation, were tried, but did not bring about the desired result. The reason for the higher value of the residue, so far as can be ascertained, is due to the unusually high silver-content of the ore.

Preliminary investigations in the laboratory lead to the belief that it is easier to dissolve gold *per se* than when combined with silver, and as the latter increases so does the rate of solution of the gold decrease. It was found in the first trials carried out with alloys of varying fineness that the solution-ratio is as follows:

Test	Fineness—		Solution-ratio
	Gold	Silver	
1	1000	0	1.75
2	800	200	1.63
3	600	400	1.33
4	500	500	1.22
5	200	800	1.02
6	0	1000	1.00

It is interesting to note that the above solution-ratios, 1 for silver and 1.75 for fine gold, bears a close agreement with the ratio of the atomic weights of these two elements, silver 108, gold 197, silver 1, gold 1.82.

In the re-treatment of residue from the roasting-plants of this field the following facts are gathered:

The Great Boulder Proprietary pumps its residue to

the dump approximately one mile from the plant. The settled solution or water immediately recovered from the dump passed through zinc-boxes, and the bullion fineness is gold 600, silver 400, whereas the bullion recovered from the mine is: gold, 819; silver, 161; and base, 20. This would seem to indicate that the comparatively silver-free gold is the first to dissolve and the silver-gold alloy is with more difficulty recovered. In the re-treatment of residue produced from this mine in 1905, and now being treated by lessees, the bullion has a fineness of but 400 gold and 600 silver. Both instances quoted seem to verify the belief that where silver, in combination with the gold, is unusually high, there is difficulty in producing a low-gold residue.

The following minerals are known to occur in the ore, and are often intimately associated with one another: hessite, Ag_2Te ; petzite, $(\text{AgAu})_2\text{Te}$, ratio, gold 1, silver 3; sylvanite, $(\text{AuAg})\text{Te}_2$, ratio, gold 1, silver 1; calaverite, $(\text{AuAg})\text{Te}_2$ and AuTe_2 , ratio, gold 6, silver 1, and free gold of varying fineness, that is, in size.

In these circumstances the gold and silver contents may come into the plant in such a variety of ways, that it would not be correct to lay down the axiom, that high silver-content in conjunction with the gold would always result in higher gold-value in the residue. Free gold associated with hessite would probably have no effect; nor free gold with calaverite and hessite; whereas either petzite or sylvanite in which the Au and Ag is chemically combined, the gold may be more difficult to dissolve. It would be quite impossible from the daily assays of the head and residue samples for Au and Ag to say, with any degree of accuracy, in what way the mineral-contents came in; it is also outside the range of chemical analysis even to determine the several minerals in such minute quantities.

Any finality of opinion on such an abstruse question can only be deduced from general results and the known facts observed from time to time in metallurgical practice.

THE freezing-point of mercury has been definitely determined by the U. S. Bureau of Standards. It has long been popularly supposed that mercury freezes at 45° F. below zero. The recent investigation shows this to be an error. Mercury freezes at -38.87° C. (-37.97° F.) The information is important to those who make industrial use of mercury, and particularly to the manufacturers of mercurial thermometers.

THE United States is exporting crude steel at the rate of over 1,200,000 tons annually. In August last over 160,000 tons was shipped abroad.

*Abstract from *Monthly Journal* of Chamber of Mines, Kalgoorlie, Western Australia.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

THE FIRST reported discovery of gold in the United States was in the State of Georgia in 1829.

HEAVY LOSS of quicksilver per ton of ore treated in a stamp-mill indicates that the 'quick' is being over-fed. It is more likely to happen where the ore is very low-grade than elsewhere.

RUBBER GASKETS in steam-joints, such as flanges and unions, can be prevented from adhering to the surface of the metal by rubbing a little graphite and oil on the surface of both gasket and metal before connecting the pipe.

DURIRON, an acid-resisting alloy used in chemical works, laboratories, and where acids are flowing, consists of 14 to 14.5% silicon, 0.25 to 0.35% manganese, 0.2 to 0.6% carbon, 0.16 to 0.2% phosphorus, and under 0.05% sulphur, the remainder being iron. Its melting-point is from 2500 to 2550° F. The specific gravity is 7.

STUMPS of Norway pine submitted to destructive distillation at the Buffalo mine at Cobalt, yielded 26 lb. of oil from 106 lb. of wood charged into a retort. Further refining gave 31% of pine-oil at a temperature of 190 to 200° C. It was found by T. R. Jones that these stumps were better than other woods in the district, and distillation need not be carried above 400° C.

A HIGH ACCELERATION STRESS, due to quick start, may not on the surface appear dangerous to a wire rope, but if the comparison were made of the micro-structure of the steel before and after such stressing, a visible change would be perceptible. In hoisting and haulage work it is important to apply the load gradually, that the rope may not be subjected to sudden stresses, which decrease wire-rope life.

ZINC ORES of New Jersey differ materially from those generally mined throughout the West. The New Jersey ores consist of a mixture of franklinite, zincite, and willemite in a gangue of garnet and calcite. The ore is crushed and run through a magnetic separator which makes three products: willemite, used in making spelter; franklinite, employed in the manufacture of zinc oxide; and a mixed product also used in making zinc oxide.

TUNGSTEN minerals are frequently found in pegmatite dikes in which mica may be one of the constituents. Formerly mica was a mineral difficult to eliminate from the crushed ore in the concentration mills, but the problem seems to have been solved at the tungsten mill at Hill City, South Dakota, where the ore, after passing crushers and rolls, goes to a pneumatic jig that blows

the mica away from the granular minerals before the pulp comes in contact with water. In the subsequent treatment, after removal of the mica, the pulp is passed through sizing-screens, from which the various grades go to jigs, tables, and slimers, and finally the slime is treated by flotation, and on a canvas plant.

WHEN A FRESH POOL of oil is opened, an excessive quantity of gas is generally produced with the oil. In a short time the flow of gas is greatly reduced in volume and pressure, because the gas tends to separate from the oil and escape more rapidly. Holding back the escape of the gas retards the oil production but conserving the gas prolongs the life of the well and increases the total amount of oil raised to the surface by flowing.

ALUMINUM finely powdered enters into the composition of two extremely powerful explosives. One of them, ammonal, consists of one part of aluminum and eight parts ammonium nitrate. This mixture is used to charge shells, and is one of the explosives which probably will never be employed as a propelling force for the reason that its explosive action is so sudden that no gun thus far made would be strong enough to resist it. Or, if the gun were not shattered by the explosion, the interior of the chamber would be likely to be damaged by it.

MANGANESE ore giving by analysis 30 to 40% Mn, 10 to 20% Fe, 3 to 10% SiO₂ with low phosphorus content would be classed as a manganiferous-iron ore. When earthy it is called 'wad'. An ore in which manganese equals the amount of iron present is usually smelted, making low-grade ferro-manganese. In the United States the price paid for manganese ore is governed largely by the specifications of the Carnegie Steel Co. of Pittsburgh. High-grade manganese ores command a much higher price than that above described, but there is a correspondingly smaller demand for first-class ore. Numerous attempts have been made to concentrate manganese ores, but thus far without much success.

CUPRO-TUNGSTITE is one of the less common of the tungsten-bearing minerals. It has a highly vitreous lustre, a hardness of 4.5 to 5, and is pistachio green, passing to olive and leek green. In composition it is variable. One variety is tungstate of copper, CuWO₄, another is tungstate of copper and calcium (CaCu) WO₄. Before the blow-pipe it fuses to a black glass and colors the flame an intense green. It is easily soluble in hydrochloric acid, and gives the usual blue color on addition of tin or zinc. It occurs in the copper mines near Santiago, Chile, and in the vicinity of La Paz, Lower California. Also in the mines of the Suan Concession, in Korea, where it accompanies the ordinary calcium tungstate, scheelite. Cupro-tungstite may easily be mistaken for some of the minerals of the epidote group—zoisite or epidote, particularly the latter, some varieties of which it greatly resembles. Epidote and zoisite are much harder than cupro-tungstite, the former having a hardness of 6 to 7, being about the same as feldspar.

Copper, Lead, Quicksilver, and Zinc in 1916

The U. S. Geological Survey has published the following preliminary figures and remarks concerning the above metals:

COPPER

The production of copper in the United States in 1916 surpassed all previous records. Preliminary figures have been collected by B. S. Butler, who has received reports from all plants known to produce blister copper from domestic ores and refined copper. At an average price of about 27c. per pound the output for 1916 has a value of \$520,000,000, compared with \$242,900,000 in 1915 and with \$189,790,000 in 1913.

The figures showing smelter production from domestic ores represent the actual production of most of the companies for 11 months, and an estimate of the output for December. The figures of a few companies for November were not available, and these companies furnished estimates for the last two months of the year. According to the data received, the output of blister and Lake copper from domestic ores was 1,928,000,000 lb. in 1916, against 1,388,000,000 lb. in 1915, and 1,224,000,000 lb. in 1913. The output of refined copper (electrolytic, Lake, casting, and pig) from primary sources, domestic and foreign, for 1916, is estimated at 2,311,000,000 lb., compared with 1,634,000,000 lb. in 1915, and with 1,615,000,000 lb. in 1913. The production of copper from the mines of the United States for 1916 was more than double that of 10 years ago and more than four times that of 20 years ago. The profit resulting from the domestic production was far greater in 1916 than in any previous year. It is probably safe to say that it exceeded \$300,000,000.

According to the Bureau of Foreign and Domestic Commerce, imports of all forms of unmanufactured copper for the first 10 months of 1916 amounted to 397,594,000 lb. This compares with an import of 265,677,000 lb. for the first 10 months of 1915. The imports for the 12 months of 1915 were 315,698,449 lb. Exports of pigs, ingots, bars, plates, sheets, rods, wire, etc., for the first 10 months of 1916, amounted to 655,472,000 lb., compared with an export for the first 10 months of 1915 of 529,286,000 lb. Exports for 1915 were 681,917,000 pounds.

At the beginning of 1916 there was 82,400,000 lb. of refined copper in stock in the United States. This quantity added to the refinery production gives a total available supply of 2,393,000,000 lb. of refined copper. On subtracting from this amount the exports for the first 10 months and the estimated export for the last 2 months, it is apparent that the supply available for domestic consumption is materially greater than the 1,043,000,000 lb. in 1915, no account being taken of stocks held at the close of the year.

The average price of copper for 1916 showed a marked increase over that of the preceding year, being slightly above 27c., compared with 17.4c. in 1915. Much of the copper was sold several weeks or months in advance of delivery, and it is therefore probable that the actual average price received differs somewhat from the average of the daily quotations for immediate delivery. The general trend of the market would indicate that the actual price received may be below that indicated by the average of quotations.

Arizona made a record production. The total may reach 675,000,000 lb., compared with 432,000,000 lb. in 1915. This exceeds the total output of the United States as late as 1902. Montana, with more than 350,000,000 lb., exceeded its previous record production of 314,900,000 lb. in 1912. This compares with about 268,000,000 lb. produced in 1915. Michigan, in common with the other important copper-producing States, made a record production. The output for 1916 was 269,000,000

lb., as compared with 238,900,000 in 1915, the previous record production. Utah may show an increase of 60,000,000 over the previous record production of 175,000,000 lb. in 1915. The output from Alaska estimated at over 120,000,000 lb. compares with 70,600,000 lb. for 1915. The production from Nevada will nearly reach 100,000,000 lb., which compares with the previous largest production of 85,200,000 lb. in 1913 and with 67,700,000 lb. in 1915. New Mexico will probably reach 90,000,000 lb., compared with 62,800,000 lb. for 1915. California, with a production that may exceed 60,000,000 lb., showed a large increase over the previous record production of over 53,000,000 lb. in 1909. In 1915 the production was 37,600,000 lb. Tennessee alone among the important copper-producing States failed to show a record output. The production was probably slightly below 15,000,000 lb., as compared with over 18,000,000 lb. for 1915.

LEAD

The lead industry in 1916 made good gains in output, both in mining and smelting. The lead content of ore mined in the United States in 1916 was 622,000 short tons, compared with 561,639 tons in 1915, an increase of 60,000 tons, or over 10%. The average price of lead in 1916 was so much higher than in 1915 that the increase in value of the mine output of lead was about 50%.

The Northport Smelting & Refining Co. in March blew in the re-modeled smelter at Northport, Washington, and later in the year added two more lead furnaces, making four in all. The operation of the smelter gave an impetus to the production of lead in Washington, the output of which was four times as large as ever before. Construction on the Bunker Hill & Sullivan smelter was started at Kellogg, Idaho, and it is expected to be in operation in the spring of 1917.

The State that recorded the largest gain in lead production was Missouri, which made an increase of over 25,000 tons. Good gains were also made by California, Idaho, Nevada, Utah, and New Mexico.

The following estimates have been compiled without change by C. E. Siebenthal from reports made to the Survey, by all the lead refineries and soft-lead smelters in operation during the year. These reports give records of the actual production for the first 10 or 11 months and estimates of the output for the remainder of the year. The statistics of imports, exports, and lead remaining in warehouse have been made up from the records of the Bureau of Foreign and Domestic Commerce for 10 or 11 months, and estimates for the remainder of the year.

The production of refined lead, desilverized and soft, from domestic and foreign ores in 1916 was 579,600 tons, worth at the average New York price \$78,826,000, compared with 550,055 tons, worth \$51,705,000, in 1915, and with 542,122 tons, worth \$42,286,000, in 1914. The figures for 1916 do not include an estimated output of 21,800 tons of antimonial lead, worth approximately \$4,283,000, compared with 23,224 tons in 1915 and with 16,667 tons in 1914. Of the total production, desilverized lead of domestic origin, exclusive of desilverized soft lead, is estimated at 324,000 tons, against 301,564 tons in 1915 and 311,069 tons in 1914; and desilverized lead of foreign origin at 21,400 tons, compared with 43,029 tons in 1915 and 29,328 tons in 1914. The production of soft lead, mainly from Mississippi Valley ores, is estimated at 234,200 tons, compared with 205,462 tons in 1915 and 201,725 tons in 1914. The total production of desilverized and soft lead from domestic ores was thus about 558,200 tons, valued at 75,915,000, compared with 507,026 tons, valued at \$47,660,000 in 1915, a gain of 51,000 tons.

Of this gain in domestic output, about 29,000 tons was made in soft lead, and 22,000 tons in domestic desilverized lead. In consequence of the great demand for lead a considerable quantity of secondary lead (about 7000 tons) and secondary antimonial lead (over 5000 tons) was recovered at the regular smelters. The final figures for the production of soft lead will show an increase of a few thousand tons over those here given, for the reason that the smelters and refiners of argenterous lead undoubtedly treated more or less soft lead ore from the Mississippi Valley which in their preliminary estimates is not distinguished from silver-lead ore.

Imports of lead are estimated at 20,600 short tons of lead in ore, valued at \$1,575,000; 9200 tons of lead in base bullion, valued at \$1,091,000; and 6000 tons of refined and old lead, valued at \$803,000, a total of 35,800 tons, valued at \$3,468,000, compared with 51,496 tons in 1915. Of the imports in 1916 about 19,500 tons came from Mexico, against 47,124 tons in 1915. Exports of lead of foreign origin smelted or refined in the United States showed a great decrease. They were estimated at 9350 tons, worth \$3,468,000, against 38,445 tons in 1915, and 31,051 tons in 1914. This does not include foreign lead manufactures exported with benefit of drawback, which amounted to 4744 tons in the first half of 1916. For the last three years notable quantities of domestic lead have been exported to Europe, and the total for 1916 is estimated at 108,200 short tons, valued at \$14,787,000, compared with 87,092 tons, valued at \$7,796,998, in 1915. The imports of lead for the first 10 months of 1916 originated as shown in the following table:

LEAD IN ORE AND BASE BULLION IMPORTED FROM JANUARY TO OCTOBER, 1916, IN SHORT TONS

	Lead in ore	Value	Lead in base bullion	Value
Mexico	8,193	\$616,836	8,927	\$955,949
Canada	2,260	161,482	3	198
Peru	461	44,305	48	4,528
Chile	2,322	199,880
England	115	11,109
Australia	896	53,749
All other	577	48,002	18	1,747
Total	14,824	\$1,135,363	8,996	\$962,422

The amount of lead available for consumption during 1916 may be estimated by adding to the stock of foreign lead (domestic stocks are not known) in bonded warehouses at the beginning of the year (12,169 short tons) the imports (about 35,800 tons) and the domestic production (558,200 tons), making an apparent supply of 606,169 tons. From this are to be subtracted the exports of domestic lead (108,200 tons), the exports of foreign lead (about 9350 tons), the foreign lead contained in articles exported with benefit of drawback (about 9000 tons), and the stock in bonded warehouses at the end of the year (assumed to be the same as at the end of November, 8387 tons), leaving as available for consumption 471,200 tons, compared with 426,751 tons in 1915.

Lead began the year at New York with a price of 5.5c. per pound, the minimum price of the year, and rose to 8c. early in April, this being the maximum figure. A long decline carried the price down to 5.95c. in the early part of August. Another rise reached 7c. about the middle of September, after which the price remained stationary until early in December, when it advanced to 7.5c., and it closed the year at about that figure. The average New York price for the year was 6.8c., compared with 4.7c. in 1915, 3.9c. in 1914, and 4.4c. in 1913. The London price of lead was higher than the New York price for the first quarter, but below it for almost the whole of the last three quarters of the year. The London price started the year at £30 7s. 6d. per long ton (6.57c. per pound) and rose to £36 7s. 6d. (7.87c.) in the latter part of March. Paralleling the New York market, a long decline brought the price down to £28

(6.06c.) in July, at which it remained through the month. A sharp rise followed a decline and another rise brought the price up to £31 10s. (6.82c.) late in September. A decline to £30 10s. (6.6c.) took place early in October, after which the price remained practically stationary. The average price of lead at London during 1916 was about £31 1s. 7d. per long ton (6.7c. per pound).

QUICKSILVER

The domestic output of quicksilver in 1916, according to preliminary figures collected from the individual producers by H. D. McCaskey, was 28,942 flasks of 75 lb. each, valued, at the average domestic price for the year at San Francisco (estimated at \$125.90 per flask), at \$3,643,800. This was the greatest output in quantity since 1905 and not only the greatest in value since 1875 but, except the value of \$4,228,538 for that year, was the greatest in the history of the domestic industry, dating back to 1850. Compared with the Survey's final figures of output for 1915, which gave a production of 21,033 flasks, valued at \$1,826,912, the preliminary figures for 1916 show an increase of 7909 flasks, or 38%, in quantity and of \$1,816,888, or 99%, in value.

The productive States, named in order of rank, were California, Texas, Nevada, Oregon, Washington, and Arizona, all of which increased their output except Nevada, although Arizona has produced only a nominal quantity to date and Washington had produced none prior to 1916.

The output for California in 1916 was 20,550 flasks, valued at \$2,587,245, against 14,283 flasks, valued at \$1,174,881, in 1915. Quicksilver prospecting and mining were generally active in California in 1916, and some of the large furnaces were worked profitably upon ores of lower grade than has ever been reported in the history of the industry. Many additions to plants, including experimental forms of roasters and condensers and concentrating appliances, were brought into use in the effort not only to increase the output so as to take advantage of high prices but also to try out new methods of recovery while the industry could afford to pay for experimentation. New retort plants were built at many of the smaller mines in California, as well as in Oregon, Washington, Nevada, and Arizona. The famous New Idria mines, in San Benito county, made a largely increased yield, and again led the country and the Western Hemisphere, and a large output was also made from the New Guadalupe and New Almaden mines of Santa Clara county, the Oceanic of San Luis Obispo, the Helen of Lake county, the Cloverdale of Sonoma county, and the St. Johns of Solano. Many of California's quicksilver mines showed increased output in 1916.

The combined output of Texas and Nevada in 1916 was 7975 flasks, valued at \$1,004,052, against 6744 flasks, valued at \$651,611 in 1915. In the Terlingua district of Brewster county, Texas, the Chisos mine remained the second largest producer in America, and the Big Bend, Mariposa, and Colquitt-Tigner mines, all re-opened in 1916, added further notable output.

The Goldbanks mine, in Humboldt county, Nevada, became a large producer, the Cinnabar King, Red Devils, and Lost Steers, in the new district near Mina, in Mineral county, made together an important initial output, and the Mercury and Nevada Cinnabar mines, near Ione, Nye county, continued production though on a smaller scale than in 1915.

The combined production of Oregon and Washington in 1916 was 412 flasks, valued at \$51,870, against a nominal output from Oregon alone in 1915.

In Oregon there was a considerable yield from the Black Butte mine in Lane county, re-opened in 1916. In the Meadows district of Jackson county there was a small preliminary output from the Little Jean, Ranier, and Mrs. Dewey properties. In this district also a large amount of development work was done on the Mountain King property, which may become an important producer when a reduction plant is built for the ores. In Douglas county a small yield was made from

the Bowers prospect, and elsewhere in Oregon there was lively prospecting for quicksilver ores.

In Washington, near Morton, in Lewis county, considerable prospecting was done on the Morton Cinnabar and Mother Lode properties especially, and the former made a production early in the year from some rich surface ore tested in a modern retort.

Never before in the history of the industry have such prices been obtained for quicksilver as in the first three months of 1916. The average San Francisco domestic price for January was \$222 per flask, and this rose to \$295 for February, during which some metal is reported to have been sold for \$400. The average declined to \$219 in March, to \$141.60 in April, to \$90 in May, and to \$74.70 in June. The price then steadied, and from July to December the monthly averages did not fall below \$74.50 nor rise above \$81.20. The year ended with an average for December of about \$80 per flask. The high prices were due to large demands resulting from war conditions, which greatly increased domestic use in manufacture and kept down competing imports. Notwithstanding increased output the demand apparently absorbed about all the available metal, and few sales were reported at a rate less than \$1 per pound.

For the first nine months of 1916 the imports of quicksilver were 5245 flasks, at an average value of \$93.47 per flask. Of these imports, 3014 flasks came in during the first quarter of the year, 1698 flasks during the second, and only 533 during the third. The total imports for consumption for 1915 were 5625 flasks, valued at \$282,752. Exports of quicksilver for the first 10 months of 1916 were 6689 flasks, at an average value of \$76.01 per flask. The exports were 20 flasks for the first quarter, 1350 flasks for the second, 3444 flasks for the third, and 1875 flasks for October alone.

Altogether conditions for the quicksilver industry are prosperous. With increasing output, steady demand at high prices, decreasing imports, and increasing exports the quicksilver mines may look back upon 1916 as the best year within a generation, and the outlook for the immediate future is correspondingly bright.

ZINC

The zinc-mining and zinc-smelting industries experienced a year of prosperity in 1916. According to the best information available at this time the recoverable zinc content of ore mined in the United States was about 708,000 tons, compared with 605,915 tons in 1915, and 406,959 tons in 1914. The largest district gain was made by the Joplin region, which had an increase of over 40,000 tons. Montana made a notable gain and from the returns available seems to have taken second place, but it will require complete figures to decide. Good gains were also made by the upper Mississippi Valley region, Colorado, Tennessee, Idaho, Nevada, New Mexico, New York, Arkansas, and Washington. The Eastern States produced 148,000 tons, or 21%, the Central States 274,000 tons, or 39%, and the Western States 286,000 tons, or 40% of the total output of zinc in ore.

The following figures have been compiled without change by C. E. Siebenthal, from reports furnished by all operating smelters of zinc ores except one small plant, showing their output for the first 11 months of the year and their estimated output for December. The production of the smelter not reporting, which operated intermittently, has been estimated on the basis of its output for the first half of the year. Figures showing the imports and exports for 10 or 11 months were obtained from the Bureau of Foreign and Domestic Commerce, and to these figures have been added estimates for the remainder of the year.

There was much activity in the construction of retort zinc smelters during 1916, and considerable additions are under construction or planned for 1917. The number of retorts at the beginning of 1916 was 156,568, on July 1 it was 196,640, and at the end of the year it was 213,840, besides 13,648 additional retorts being built or planned. The Athletic Mining & Smelt-

ing Co. is building a smelter of 2400 retorts at Fort Smith, Arkansas, to be completed in March, 1917. The United Zinc Smelting Corporation is building a smelter to have 6912 retorts at Moundsville, West Virginia, which will be completed early in the year. Additions are under way at Pueblo, Colorado; Peru and East St. Louis, Illinois; and Blackwell, Quin-ton, and Sand Springs, Oklahoma. The Berger Manufacturing Co., of Canton, Ohio, completed plans for a smelter at Fort Smith, Arkansas, but the construction is yet in abeyance. The full retort capacity was not utilized in smelting ore at any time during the year. A large number of retorts were occupied in re-distilling prime western spelter. Many retorts were idle during parts of the third and fourth quarters of the year but resumed late in the year, though a considerable number were still idle in December.

The capacity, by States, of the regular zinc smelters, together with the additions now planned for 1917, is as follows:

	Retorts in operation Dec. 15, 1916	Retorts idle Dec. 15, 1916	Retorts to be added in 1917
Illinois	42,118	800	1,600
Kansas	37,198	6,778
Oklahoma	68,231	6,235	2,472
Other States	51,568	912	9,576
	199,115	14,725	13,648
	213,840		

Two new smelters using large graphite retorts were built during 1916. These were the plants of the Eastern Zinc Refining Co., at Brooklyn, New York, with 8 large retorts and 16 more under construction or planned, and of the M. Moosowitz & Son Metal Co., at Trenton, New Jersey, with 21 retorts. There are now five such plants, with 153 retorts. Six electrolytic zinc plants were in operation in 1916. Four units of the large Anaconda plant at Great Falls, Montana, went into operation, and it is thought that the last unit will be completed about the first of 1917. The small Anaconda electrolytic plant at Anaconda, Montana, has been dismantled. The plant of the River Smelting & Refining Co., at Keokuk, Iowa, was active, and experiments were continued at the Bully Hill plant in California. The electrolytic zinc plant of the Judge Mining & Smelting Co., at Park City, Utah, and that of the Mammoth Copper Co., at Kennett, California, will be ready for operation by the middle of 1917. The Murray experimental plant of the American Smelting & Refining Co. is closed, and plans for a larger plant are abandoned for the present at least.

The production of spelter from domestic ore in 1916 is estimated at 553,000 short tons, worth, at the average St. Louis price, about \$150,000,000, and from foreign ore at 105,000 tons, a total of 658,000 tons, worth \$180,000,000, compared to a total of 489,519 tons in 1915 (458,135 tons of domestic origin, and 31,384 tons of foreign origin), worth \$121,400,000 at the average St. Louis price. This was a gain of 169,000 tons in quantity and an indicated gain of more than \$58,600,000 in value. The actual gain in value, however, was considerably less because much of the spelter was sold for future delivery at prices from 1 to 2c. below the quotations for immediate delivery. Included in the output is 11,878 tons of electrolytic spelter, of which a part was refined by electrolysis from prime western spelter. The output of zinc dust was about 2500 tons, compared with 1755 tons in 1915. The output of secondary spelter re-distilled at regular smelters and at the smelters with large retorts was about 32,000 tons. It is probable that the output of re-melted spelter was not less than that of the preceding year, 23,000 tons, which would give a total of 55,000 tons of secondary spelter. Adding this to the production of primary spelter gives a grand total of 713,000 tons of spelter made in the United States in 1916.

The production of primary spelter from both domestic and

foreign ores, apportioned according to the States in which it was smelted, by six-month periods, was as follows, in tons:

State	1915		1916	
	First half	Second half	First half	Second half
Illinois	74,982	84,976	90,082	90,268
Kansas	35,247	66,176	74,592	65,924
Oklahoma	51,172	58,036	73,298	90,790
Other States	55,131	63,799	78,480	95,054
Total	216,532	272,987	316,452	342,036
	489,519		658,488	

Exports of spelter and sheets made from domestic ore are estimated at 167,000 short tons, worth \$52,200,000, compared with 118,603 tons, worth \$29,537,680, in 1915. Exports of spelter made from foreign ore are estimated at 43,500 tons, valued at \$7,500,000, compared with 13,720 tons in 1915. The exports of zinc manufactures fell off to \$573,000 in 1916, from \$2,173,089 in 1915. The exports of brass are estimated at 110,300 tons, valued at \$65,085,000, compared with 33,136 tons, worth \$12,435,906, in 1915. Manufactures of brass were exported to the value of about \$237,300,000, compared with \$41,117,771 in 1915. The value of cartridges exported in 1915 was about \$59,000,000, against \$24,814,679 in 1915. Exports of domestic zinc ore were about 78 short tons, valued at \$3992, compared with 832 tons in 1915. Imports of spelter (mostly scrap, probably) are estimated at 600 short tons, valued at about \$100,000, compared with 904 tons in 1915. Zinc-dust was imported to the amount of 900 tons, worth \$330,000. Imports of zinc ore in 1916 were approximately 371,000 short tons, containing about 140,000 tons of zinc and worth about \$11,800,000, compared with 158,852 tons of ore, containing 57,669 tons of zinc, in 1915. The zinc imports for the first 10 months of 1916 originated as follows, in tons:

Country	Ore	Zinc-content	Value
Canada	17,899	7,195	\$ 455,754
Mexico	139,803	43,096	5,368,113
France	3,884	1,422	56,542
Spain	49,769	20,541	1,385,025
Italy	12,550	5,783	394,782
French Africa	2,464	1,152	73,564
French East Indies	1,653	746	55,407
China and Hong Kong....	9,541	4,569	344,192
Australia	94,584	41,707	2,574,476
Other countries	841	265	20,601
Total	332,988	126,476	\$10,728,466

The apparent domestic consumption of spelter in 1916 may be computed as follows: The sum of the stock on hand at smelters at the beginning of the year, 14,253 tons, plus the imports, 600 tons, and the production, 658,000 tons, gives the total available supply—672,853 tons. From this are to be subtracted the exports of domestic spelter and sheets, 167,000 tons, the exports of spelter made from foreign ore, 43,500 tons, and the stock on hand at smelters at the end of the year (to be exact, on December 15), 17,300 tons, or a total of 227,800 tons, leaving a balance of 445,000 tons as the apparent domestic consumption. This calculation takes no account of the stocks of spelter held by dealers or consumers. On comparing the consumption in 1916 with the 364,382 tons consumed in 1915 and the 299,130 tons consumed in 1914, it appears that the indicated consumption is large, because the exports of brass and manufactures of brass were large. The stock of spelter at smelters on December 15 shows a reduction of 6500 tons when compared with the 23,879 tons shown by the mid-year figures.

The price of spelter at St. Louis at the beginning of 1916 was 17.2c. per pound. By the middle of February it had risen to 20.9c., the high point of the year, after which it dropped sharply to 16.5c. by the middle of March, but rose quickly

again to 19.12c. at the middle of April. Then began a long sharp decline which brought the price to 8.8c. at the middle of July. A recovery to 10.7c. was followed by a drop to 8.4c. on August 10, the lowest price of the year. By fits and starts the price rose to 13.2c. at the end of November, after which it gradually declined, closing the year at about 10c. The average price for the year for immediate delivery at St. Louis was 13.7c., compared with 14.2c. in 1915 and 5.1c. in 1914.

The price of spelter in London was uniformly about 2c. higher during the year than at St. Louis. For a few days in the latter part of November the London price was lower than the St. Louis price. The price at London opened at £90 per long ton (19.6c. per pound) and after sagging slightly through January rose sharply to £111 (24.1c.) at the beginning of March. This exceeded the maximum price for 1915, which was £110 (23.8c.). A sharp decline to £85 (18.5c.) by the middle of March was followed by a rise to £105 (22.8c.) at the end of April. The great decline then set in, which brought the price down to £44 (9.6c.) in the early part of July. A sharp recovery to £60 (13c.) at the end of July was followed by a drop to £44 (9.6c.) in the early part of August. Then followed a series of sharp oscillations, which brought the price to £60 (13c.) by the beginning of December. The price declined a little through the last month of the year and at the end was around £54 (11.7c.). The average London price for the year was about £72 7s. 7d. per long ton (15.7c. per pound).

CALIFORNIA MINERAL OUTPUT

The statistical division of the State Mining Bureau, under the direction of Fletcher Hamilton, has made a careful estimate, from information now available, of the mineral production of the State for the year 1916. This estimate is in advance of the actual figures which will be available later. The indications are that the total for all products, metallic and non-metallic, will approximate \$119,000,000, against \$96,663,369 in 1915, and for the first time in the history of the State exceeding \$100,000,000 in value. The major portion of the increase is due to copper. The output of that metal increased about 50% in quantity and over 60% in price per pound; more than doubling the total value of the year's product. That gold practically held its own in spite of the strike shut-down on the Mother Lode in Amador county, and an increase of about \$500,000 in silver are attributable largely to the increase in copper output. Of the other important metals, tungsten, lead, zinc, and quicksilver, all made noteworthy gains. Petroleum shows an increase of about 2,000,000 bbl. in quantity and some \$5,000,000 in value. As to chrome, magnesite, and manganese, it is too early yet to obtain any definite idea of the quantities, but it seems likely that the total of the three will reach at least \$1,500,000. There are two new items added to the commercially productive list this year; molybdenum and strontium, small lots being sold.

The estimated values for 1916 are:

Gold	\$22,500,000
Silver	1,400,000
Tungsten	4,000,000
Copper	17,000,000
Lead	1,000,000
Zinc	2,000,000
Quicksilver	2,500,000
Antimony, iron, molybdenum, platinum.....	59,000
Petroleum	49,000,000
Chrome, magnesite, manganese	1,500,000
Natural gas	1,800,000
Brick, cement, building stone, crushed rock, etc....	13,200,000
Miscellaneous industrial materials	1,255,000
Salines	2,100,000
Total	\$119,314,000

provide for an increased production from the Blue Bell and De Soto mines.

The plant of the Bradshaw Reduction Co. (formerly the Randolph-Gemmill) was also successful last year. Prior to last March it was run only experimentally. From then until September 26, when it was closed pending mechanical changes and an increase in capacity from 70 to 150 tons daily, the plant treated 9300 tons of tailing from the Crown King dump. Fifty-five carloads of iron concentrate was shipped from the plant to the Humboldt smelter during that period. The concentrate carried about \$18 gold, \$6 silver, and \$10 copper per ton and netted \$45,000. In addition, 800 tons of zinc concentrate was shipped to smelting points in Kansas and Oklahoma at a net profit of more than \$30,000. The plant will resume operations early in March, and after treating the remaining 2500 tons of Crown King tailing will handle ore from the Crown King, War Eagle-Gladiator, Wildflower, and other mines of the Crown King district. The properties specifically mentioned are held under lease and option by the Bradshaw Reduction Co. The Crown King is one of a number in Yavapai county and other parts of Arizona formerly worked profitably by Frank M. Murphy and others. It has a production record of upward of \$2,000,000.

The Commercial and Copper Chief mines produced a considerable quantity of ore during 1916, and may be depended upon to increase this during 1917. The first mentioned, in Copper Basin, 8 miles from Prescott, is owned by the Phelps-Dodge interests. Its present capacity is 100 tons of 7% copper-oxide ore daily. This ore is used as a flux by the local and outside smelters. The shaft at the Commercial is to be deepened during 1917 with the object of opening ore in the sulphide zone. The Copper Chief, near Jerome, is shipping three carloads of copper ore per week to outside smelting points, and in addition is sending an average of 100 tons of gold-silver ore daily to the mill near the main shaft. Ore reserves in the mine are, however, somewhat depleted, owing to the fact that they were drawn upon extensively during 1916 and that no effort has been made to open the orebodies at deeper levels. It is understood that the shaft is to be deepened during 1917.

In the latter part of 1916 the 150-ton mill of the Stoddard Mining & Milling Co. began treating copper-gold ore from the Binghamton mine with satisfactory results, using oil flotation. Early in 1917 the plant's capacity is to be increased to 300 tons daily, with the object of treating ore from the Copper Queen mine, in addition to ore from the Binghamton.—The old Treadwell smelter—renovated and modernized—was blown-in about the middle of December. It is now owned by the Great Western Smelting Co., and will be used for reduction purposes by the Big Ledge company. The Henrietta mine, owned by this company, was recently examined by W. H. Weed, who classified it as a "good little mine."—The 80-ton cyanide plant of the Big Pine Consolidated Mining Co., 12 miles south of Prescott, began the successful treatment of ore in the latter part of 1916, as did also the Cash, the Arizona, and the Octave.

LEADVILLE, COLORADO

DISCUSSION ON DREDGING IN THE WINTER

The following notes on the Derry Ranch dredge are of interest:

The dredge was started on April 27, 1916, but the gravel handled was small during that month, owing to the fact that the pond had to be cleared of ice before digging operations could be started. On May 1 the boat was in full swing, and continued until December 8. The yardage handled in December was comparatively small, on account of the accumulation of ice. When this dredge was built, it was contemplated that it would probably operate all winter, notwithstanding the fact that the climatic conditions are a little more severe than those encountered in any other dredging area in the States.

However, it was soon noted that when the severe winter set in, the yardage handled immediately decreased and consequently operating costs materially increased. The management decided that it would be poor policy to mine the limited amount of ground at its disposal, under these much higher operating costs, when the same ground could be handled a few months later at a much lower cost. The only advantage gained would be the four months' interest on the output; this would nowhere near equal the additional cost of production. It is a question whether winter dredging operation pays, excepting where it becomes necessary, in order to hold a large and well-organized crew together. The Conrey Placer Co., of Montana, which has conducted its dredging operations throughout the winter for a number of years past, now admits that it would discontinue this practice if it were not for the necessity of keeping the crew together. This is set forth in a bulletin issued by the U. S. Bureau of Mines written by Hennen Jennings, with a closing chapter by Charles Janin (abstracted for the PRESS of September 23, 1916). It is a fact that the Canadian Klondike Co.'s dredges, near Dawson, operate late into the winter, sometimes almost up to the first of January, but operations of this company have not been profitable. The point raised regarding the unprofitableness of dredging operations in the winter is practically a new one, and might be treated at length. The point is that generally speaking, gold dredging operations in the winter time are not warranted, owing to the additional expense and hazards. The fact that everything is cold, difficult for the men to handle, and steel parts seem to break much more readily, all increases the digging expense.

The Derry Ranch dredge has dug 500,000 cu. yd. of gravel during the past operating season, and has recovered \$120,000, and has paid out during the past year to its stockholders dividends amounting to 75% on a capital of \$100,000. This might be cited as an efficient dredging enterprise and a model of what can be done under difficult conditions. Any praise along these lines should be handed to Robert F. Lafferty, the general manager, and in full charge of operations of the boat. Of course, the dredge was brought to a high state of efficiency in the designing and building, which was done by the New York Engineering Co. A. C. Ludlum is president and principal owner of the Derry Ranch Gold Dredging Co., as well as president of the New York company.

One of the greatest economies has been secured through the low-power consumption, the average being less than 100 kw. per hour. While the price of power is high, 1.65c. per kw.-hr., still the average monthly power bills rarely exceed \$800, while the running time averages a little over 20½ hours per day.

The ground is heavy, containing large boulders, yet notwithstanding the high cost of power and the difficult digging it will be noted that the power bills are low for a 6-cu. ft. dredge averaging 63,000 yards of gravel per month. The ground in question consists of 125 acres, which has been proved to contain profitable gravel, the average value of all gravel dug to date being 30c. per yard. The ground was originally prospected by William H. Radford, and gold recoveries are proving the accuracy of his work.

Many difficult problems have been encountered in handling this ground, and the one that tends to restrict yardage and higher efficiency, is the necessity for avoiding damage to the adjacent ranches below the company's property. This necessitates the greatest care in dredge operations, in order to prevent muddy water from flowing onto the other ranches. Little water can be allowed to escape from the pond. When it does, it must be allowed to filter through the hay fields before it reaches the adjoining property.

This is the first and only dredging enterprise around Leadville, and it is confidently expected that more ground will be found in the near future, and that this work will be extended. In the Breckenridge district there are four dredges at work.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

The State Bureau of Mines considers that probably its most important accomplishment during the past year was the securing of a United States Mining Experiment Station for Tucson, to act in co-operation with the State Bureau. This means an expenditure of \$25,000 annually by the Federal Government to assist Arizona in the solution of its problems. It means much more than this, as the prime object of the station is to advise ways and means for the proper utilization of the State's resources and the conservation and prevention of waste, all of which will add much to the value of the mineral production of Arizona.

(Special Correspondence.)—The Glory Hole Bonanza Mining Co. is adding a compressor to its equipment, and intends to continue exploration with increased energy. C. E. Major is manager. There is unusual activity in the Tank Pass district, 12 miles north-west of Salome, and on the north slope of the Harcuvar mountains. The Verde Velvet has men at work, and the Paystreak is prospecting. At the Cobrita group machinery is going in and development will be pushed vigorously. All of the properties mentioned have good surface showings, and the Cobrita, on which development is further advanced than on the others, looks particularly well. These mines produce copper ore containing some gold, and it is expected that with extensive development the district will come into prominence as a copper producer. The formation is granite and schist intruded by a series of parallel dikes having a north-westerly strike and steep dip. The dike-rock is much altered but resembles andesite more than anything else. The veins contain much quartz and are parallel to the dikes. Many of the veins are found at the contact of limestone with the granitic or schistose rocks, and these veins usually have calcite as well as quartz in the gangue. The Cobrita has pay-ore at the surface, chalcopryite being abundant. The Copper Whopper, which is an old mine recently revived, has a contact vein 15 to 20 ft. wide with a well-marked gossan. The wall-rocks are limestone and schist. The latter is impregnated with copper ore.

Salome, December 27.

SALOME. It is reported that the Harqua Hala Bonanza mine has been sold to the Mudd-Jackling syndicate for \$1,000,000. Martin brothers and H. W. Stevens were the owners of this Yuma County mine. A mill is contemplated for the gold-copper ore.

CALIFORNIA

CERRO GORDO. On January 10 the Cerro Gordo M. & S. Co. paid two dividends of 2½c. each. Monthly earnings are now \$50,000.

GRASS VALLEY. The North Star Mines Co. is paying 50c. per share, equal to \$125,000. This makes over \$4,000,000 to date.

NATOMA. No. 5 dredge of the Natomas company, which has been operated for 11 years, is to be rebuilt.

(Special Correspondence.)—In the eastern part of Riverside county, overlooking the Colorado river, a few miles below the Santa Fe railroad bridge at Parker, are the Riverside mountains, which are included in the Bendigo mining district. There is considerable activity throughout the area, more than ever before, and large shipments of copper and gold ore are being made every week, especially from the Bendigo Mining Development and Calumet Mining companies, whose proper-

ties adjoin in the range. In the Bendigo are several hundred feet of development, and more than 450 tons of ore has been shipped to smelters in Arizona and at El Paso. Careful samples of ore from one of the shafts in which ore was recently cut, gave 18% copper, \$2.20 gold, and 3 oz. silver per ton. Smelter returns on previous shipments gave 12% copper and \$10 in gold per ton. Regular shipments of ore can easily be made as there are large bodies of commercial ore available, that can be handled at a fair profit. J. E. Meyer & Co. of Los Angeles, are large shareholders, and Lester F. Scott of Los Angeles is in charge of development.—H. E. Olund, manager of the Calumet property states that the company intends to build a smelter and install high-power machinery for carrying on development to great depth.—Other operators in the vicinity are the Calzona Mines, Steece Mines, and the Alice Mining companies. A project contemplated is to construct a spur 10 miles long from Vidal on the Santa Fe railroad to the mines of the district.

Parker, December 24.

REDDING. The Shasta copper belt is very busy, with over 2000 men employed. The new electrolytic zinc plant of the Mammoth company may start making metal in February. The Mountain Copper Co.'s flotation plant near Keswick is being doubled in capacity, or about 500 tons daily.

(Special Correspondence.)—Options were secured recently by Calvin M. Slawson on the East Belt and Conture mines, situated near Tuolumne, the prices to be paid being \$10,000 and \$6000, respectively. In each case three years is given in which to make payment, in the meantime the owners to receive certain portions of the gross output of the mines. Mr. Slawson will purchase machine-drills and drive the East Belt adit, now in 260 ft., an additional 300 ft. The vein will be cut at a depth of 500 feet.

A bond on the Redemption quartz claim has been given by Mrs. Eveline Ellis, of Columbia, to C. J. Bryant, of Nevada City. Of the gross output of gold, 20% is to be applied toward the purchase price, \$2000, which must be fully paid within three years.

The installation of a hoist, pump, and other machinery at the Confidence mine has been completed and the work of unwatering the 900-ft. incline shaft to bottom was started a few days ago. Buildings have also been erected and electric power brought to the property. Edmund Juessen is superintendent.

The Nevada Exploration Co. has erected a head-frame and buildings on the Loney ranch, near Mt. Pass, and is sinking a shaft to an ancient river channel from which, according to report, considerable gold was taken out years ago.

Thirty tons of ore from the Bacigalupi mine, near Tuolumne, milled last week, gave returns of \$48 gold per ton. Other mill runs will be made from time to time. Five men are employed at the property, which is being operated under lease by James Diamond and other local men.

It is reported that the management of the Dutch-App property contemplates installing a reduction plant at the App that will be one of the largest in the State. It will consist of three independent units. The surface plant at the Dutch, with its new flotation equipment, is modern and complete in every respect, but it is said that the proposed plant for the App will have a capacity three times that of the former.

Foreclosure proceedings involving the Longfellow mine, near Groveland, were instituted in the Superior Court of Tuolumne county today by James A. Murray. Among the numerous

defendants named in the complaint are A. G. Metz and G. L. Roberts, who are alleged to have given a note to plaintiff in April, 1912, for \$16,000 secured by the mining property.

Sonora, December 29.

(Special Correspondence.)—It is reported from Westville that the old Barton or Herman mine is to be re-opened.—Gold nuggets, worth from \$20 to \$50 each, have been recovered in the Glen drift-gravel mine near Duncan peak. Sacramento people have the property under bond.—Work has been resumed at the Home Ticket drift-gravel mine, with 20 men.—The Pacific drift-gravel mine is also employing 20 men.—Rich gravel has been opened in the Baltimore mine at Forest Hill. More miners have been engaged.

Towle, December 21.

(Special Correspondence.)—Zabriska on the T. & T. Railway in Inyo county is becoming important as a shipping point for the ores of that district. Among those shipping are the following miners: Paddy Miles, a car of lead ore from Virgin Springs; Hugh Frazier, a car of zinc ore from the Modine mine, with another lot ready; the old Carbonate mine under lease to G. H. McLain, Julius Sheldach, and Louis Koster, is producing high-grade ore, and a carload is to be shipped shortly; this mine is owned by Jack Salisbury of San Francisco; and Jack Rogers and Chris Zabriska are shipping high-grade silver ore from the old McShane mine. Kennedy and May of Los Angeles have started development on their talc claim, as also has J. F. Clipp. Both properties are within three miles of Ibex Springs. The Rob Roy mine, owned by the Ibex Mining Co., J. F. Kent of Hollywood, California, president, has lately been re-opened, and 12 men are employed. The ore is high-grade lead and zinc.

Zabriska, December 24.

COLORADO

Coal production of this State in 1916 totaled 10,447,028 tons, an increase of 1,731,631 tons. The principal producing counties are Boulder, Huerfano, Las Animas, and Routt. There are 12,340 men employed.

BLACK HAWK. During 1916 Gilpin county produced metals worth \$715,432, a decrease of 4% compared with 1915. Ninety mines yielded 42,000 tons of ore, a 22% drop. Gold was valued at \$439,045, copper \$111,474, and tungsten \$100,000.

BOULDER. Metal production of Boulder county last year totaled \$6,632,971. Of this, 2352 tons of tungsten concentrate sold for \$5,357,732. In 1915 the tungsten value was only \$1,625,000.

CRIPPLE CREEK. In the Cripple Creek *Times* annual mining edition, the mining editor, S. W. Vidler, reviews the events of 1916. Every part of the district shows unusual prosperity, and many old mines have proved worth while by systematic development. The year's output was \$14,399,941 from 977,819 tons of ore. Some of the principal producers were: Golden Cycle, 431,800 tons for \$7,785,100; Portland (3 mills), 463,852 tons for \$3,652,412; smelters at Denver and Pueblo, 52,590 tons for \$2,810,500; Isabella, 12,730 tons for \$34,780; and four small mills, 17,347 tons for \$54,316. The Roosevelt drainage-tunnel is now 2040 ft. east of the Elkton shaft, and 5665 ft. from the Golden Cycle shaft, towards which the tunnel is heading.

According to the *Rocky Mountain News* the gold output of this district declined from \$13,727,992 to \$12,063,390 in 1916. There was 975,270 tons of ore extracted, a decrease of 3%. The total gold output since 1891 is \$346,174,379. Dividends in 1916 totaled \$3,944,321, compared with \$6,493,225 in 1915. The dividend-payers last year were: Cresson, \$1,311,000; Golden Cycle, \$360,000; Mary McKinney, \$13,093; Portland, \$420,000; Stratton's Independence, \$165,000; Strong, \$250,000; Vindicator, \$360,000; Dr. Jack Pot, \$30,000; Isabella, \$25,282; United, \$40,000; Cripple Creek Central, \$220,000; and lessees, \$750,000. The Roosevelt drainage-tunnel was extended 2528 ft.

Some of the figures in the two above estimates do not agree,

much less with those of the U. S. Geological Survey given in the *PRESS* of January 6.

LEADVILLE. The 1916 metal output of this district was \$2,200,000 gold, \$2,228,200 silver, \$673,300 copper, \$1,956,000 lead, and \$13,532,000 zinc, a total of \$20,589,500, against \$13,839,400 in 1915. The past year's yield was the largest on record. The tonnage was 738,000, against 481,620. The producers are as follows: Western Mining Co., 250; Yak Tunnel Co., 250; Iron Silver Co., 200; Sellars group, 50; Ibex and lessees, 450; Garbutt and lessees, 100; Stars (Morning and Evening), 150; Jarbeau mines, 100; Fryer Hill mines, 100; Carbonate Hill mines, 50; Prospect Mountain, 100; small lessees, 100; and local mills (dumps), 150; a total of 2050 tons per day.

OURAY. During the year ended June 30, 1916, the Camp Bird mine produced \$800,925 from 25,601 tons of ore. The profit was \$498,438. The total to date is \$22,940,000 from 820,730 tons. Development during the year was 3936 ft. No new ore of any quantity was opened, and as the available milling ore was exhausted, work has been suspended until the lower adit has been driven 10,700 ft. To October 31, 1916, the heading was in 2944 ft. Four narrow veins were cut, carrying from 80c. to \$2.40 gold, 3 to 10 oz. silver, and 18 to 50% lead. The ground is very hard, and skilled labor has been lacking, though improving.

IDAHO

KELLOGG. The Bunker Hill & Sullivan Mining company's new smelter is considerably more than half completed, and construction is being rushed as fast as possible, according to Stanly A. Easton, general manager, who was in Spokane recently. The stacks have been erected, concrete has been poured for nearly all of the foundations, and a greater part of the brick-work has been done. Grading has been completed for the railroad tracks, two miles long, to serve the smelter, and the management expects to blow-in the plant by spring, probably by May. The refinery may not be finished at that time, but some metal will be made. Upward of 250 men are employed in construction. Deep development in the Bunker Hill & Sullivan mine has been attended with satisfactory results. The conditions in the bottom of No. 14 are as good as in any part of the mine. The lead-silver contents have held-up well. The property generally looks fine. The lowest level of the property, having a depth of 4400 ft. on the dip, has developments of ore that were viewed with much satisfaction by Robert N. Bell, State mine inspector, on the occasion of his recent visit. The Caledonia mine is yielding substantially; its earnings are \$100,000 per month. The vein in the Keating tunnel has not been found. About 4000 ft. of work has been done there, the greater part of it in cross-cutting the foot-wall. Some seams have been driven on, but little lateral work has been done.

MICHIGAN

HOUGHTON. On two levels of the Franklin mine rope-haulage is a success; the system is being applied to other levels. The Calumet & Hecla and other companies use the system also, and it is being extended.

MISSOURI

JOPLIN. During the last week of 1916 the ore market was uncertain in the Missouri-Kansas-Oklahoma region. The output was 7767 tons of blende, 1663 tons of calamine, and 1068 tons of lead, averaging \$75, \$50, and \$90 per ton, respectively. The value was \$863,624. During 1916 the total output of zinc concentrate was 368,000 tons, valued at \$30,508,161, against 309,538 tons and \$23,525,202 in 1915; and 52,195 tons of lead ore worth \$4,453,832, compared with 45,313 tons and \$2,513,448. The total value last year was \$34,961,993, a gain of \$8,900,000. Coincident with this big gain, according to the *Globe*, there has been more mill construction and greater prospect developing than in any other year in the district's history. Hundreds of thousands of dollars have been spent for new, modern mining

plants, and enormous sums for prospect drilling. With one or two exceptions, all of the centres have prospered exceedingly. While the most notable growth has been in the Oklahoma field, in the vicinity of Picher, Tar River, Century, and Baxter Springs, all parts of the field have shared generously in the unprecedented activity.

MONTANA

BUTTE. Good progress is being made in erecting the hoist at the Davis-Daly, and it is expected that the engine will be ready early in January. The new engine is a first-motion unit, having 22-in. duplex cylinders with a common stroke of 48 in. The hoist has two clutched drums, 6-ft. diameter, 56-in. face. Both drums are equipped with Nordberg axial plate-clutches and parallel-motion post-brakes. The hoist is designed to handle the following loads: Rock, 7000 lb.; skip and cage, 8300 lb.; rope, 8000 lb.; total rope pull, 23,300 lb.; depth, 4000 ft.; hoisting speed, 2000 ft. The engines are of the Corliss type and are equipped with the Nordberg four-gear reverse. Features pertaining particularly to this hoist are the use of oil for operating the brakes and clutches, and the installation of shifting-valves in the cylinder-heads. To operate the brakes and clutches by steam requires a considerable proportion of the total steam consumption of the hoist, and therefore makes a wasteful arrangement from the standpoint of steam economy. It was, therefore, decided to operate the brakes and clutches by oil furnished by a weighted accumulator. The oil supply is obtained from a triplex plunger-pump which is operated from the lay-shaft driving the valve gear, and an auxiliary motor-driven oil pump is also furnished. The hoist is equipped with a Lilly safety stop to prevent overwind, overspeeding, etc. This device is used on a number of the Anaconda hoists.

(Special Correspondence.)—At the North Moccasin property of the Barnes-King Development Co. conditions now appear more favorable for an increased production than in several months. The grade of ore was lower and costs of mining and milling higher during the last quarter, but conditions improved during the present quarter. Heavy snowfall and cold weather has interfered with the operation by the lessees of the Kendall mine, which is now owned by the Barnes-King, as the ore comes entirely from an open-cut.

The Spotted Horse mine at Maiden, which has been operated successfully under lease since 1912, has been closed temporarily for repairs. It is expected that the mine will be re-opened in a few weeks.—The Cumberland continues to open well, and is now the largest producer in the Judith mountains.—The Maginness also is maintaining a good output.

The Maginness and Cumberland mines at Maiden have been compelled to follow the course of the Spotted Horse and close for the winter. Difficulty was experienced in operating the cyanide plants during very cold weather. It also proved impossible to secure coal, due both to its scarcity and to the difficulty of hauling it through the deep snow that has fallen this winter. The Cottonwood Coal Co., at Lehigh, is at present producing at the rate of 100 tons per day, its output being taken almost entirely by the Great Northern Railway. The production in Fergus county this last year, 1916, was 220,615 tons valued at \$327,646, compared with 54,329 tons valued at \$65,442 in 1915. Most of this came from Lehigh and was sold at practically the cost of production. A small force is employed opening the gypsum property leased by the United States Gypsum Co. near Heath. It is proposed to build a mill next spring.

Fergus county has benefited from the war prices for base metals, this resulting in considerable development being done on lead and copper claims; but the War has practically stopped the production of sapphires from Yogo, which largely supplies the world's demands. The gems are all cut in Europe, and the production is entirely controlled by an English company. The small and imperfect stones are used for meter bearings, watch jewels, etc., and since the mines have ceased operations

during the last two years there is now a dearth of such stones in the market.

Gypsum claims have been located in the foothills of the Big Snowy mountains near Judith Gap. The claims are only a few miles from the railroad, and the gypsum occurs as a thick, pure bed.

Lewistown, January 3.

NEVADA

BULLIONVILLE. The Prince Consolidated company of Pioche will start its new mill at an early date. Sulphuric acid is added to the ball-mill to sulphidize the old tailing prior to flotation. Callow cells are used. A high recovery of the lead, gold, and silver is expected.

(Special Correspondence.)—A severe storm, with 15 in. of snow, and 15 to 20° below zero weather at the end of 1916,

JARBIDGE, NEVADA, LOOKING NORTH.

interfered materially with the production of the Nevada Consolidated Copper Co. Together with a shortage of coal on the Nevada Northern Railroad this will cause a decrease of production. All stripping operations were stopped, also all outside work, including construction and improvements. The suburban trains were all suspended, except the shift train to the mines, owing to want of coal. At the smelter, there is an abundance of fuel-oil and coal; but lacking to some extent at the mines.—It is said that the Giroux mine cannot obtain coal, to even start the mill, when ready, early in January.—The Ely Consolidated has been taken over by influential Salt Lake City people; C. W. Geddes is manager and W. Campbell of Cripple Creek and Goldfield, is superintendent. The boilers and hoist on the Zack shaft are being overhauled.—The Ward mine will soon be shipping ore to Utah. Recent work by those holding a bond on the property has been satisfactory in opening higher-grade orebodies, near the sulphide zone.—The old Vulcan mine in the Hunter district is shipping ore from several lessees.—The Tungstonia mine, A. R. Shepherd manager, is running continuously, being the only tungsten property in active operation.

Ely, December 27.

VIRGINIA CITY. The annual report of the Mexican company states that the mill shipped bullion worth \$446,010. Of this, the Union Con., Sierra Nevada, and Ophir companies contributed \$417,739. There was treated a total of 18,920 tons of ore. When the 2900-ft. level has been unwatered the east vein will be explored through the 2700-2900 ft. winze. The management is optimistic as to the results of this work.

UTAH

In its 118-page annual number the *Deseret Evening News* gives the following figures concerning 1916:

Ore production averaged 1,200,000 tons per month, worth \$9,000,000. The total of \$108,000,000 is almost double that of the 1915 yield. Dividends paid totaled \$24,757,480, against \$10,418,402 in 1915. Metal production was as under, from 261 producing mines, against 234 in 1915:

Metal and unit	1916	1915
Copper, pounds	248,300,982	187,671,188
Lead, pounds	260,648,327	199,967,437
Gold, ounces	190,027	174,591
Silver, ounces	15,820,713	12,313,205
Zinc, pounds	33,668,855	24,292,240
Arsenic, pounds	1,917,130	1,827,200
Cadmium, pounds	40,084

The Salt Lake Stock & Mining Exchange traded in 40,001,030 shares, valued at \$8,671,898, against 16,867,514 shares and \$3,968,516 in 1915, and 3,385,956 shares and \$693,483 in 1914. The Bingham district produced 13,900,000 tons of ore, valued at \$80,700,000, double the value of 1915. Park City mines shipped about 100,000 tons of ore and concentrate; Tintic, 400,000 tons, double that of 1915.

AMERICAN FORK. The first mill in the district, that of the Fissures Exploration Co., was started last week. The electric-driven mill is well equipped with two sets of rolls, two trommels, Callow screen, three elevators, two roughing-tables, two sand-tables, and two double-deck slime-tables. All the tables are of the Deister make. There are also three 25-ton settling bins, three pumps with direct connection for handling water and slime. There is also a boiler heating plant in the mill. The capacity is 75 tons per day. Concentrate contains up to 38% lead, with some gold and silver.

CANADA

BRITISH COLUMBIA

Dividends paid during 1916 were as follows:

	1916	1915	To date
Consolidated M. & S....	\$776,689	\$468,016	\$3,096,825
Granby	1,049,894	222,472	6,776,817
Hedley	240,000	300,000	2,063,520
LeRoi No. 2.....	59,600	1,625,220
Rambler-Cariboo	87,500	35,000	507,500
Standard	600,000	250,000	2,400,000
Mother Lode	137,500	137,500
Total	\$2,891,583	\$1,335,088	\$16,607,382

ONTARIO

BOSTON CREEK. The Crown Reserve Company of Cobalt has taken an option on the O'Donald gold claims, on which some good ore has been found.

KIRKLAND LAKE. Wiring for the new transmission-line, 65 miles long, should be completed by January 15. The sub-station, of 5000 hp., is between the Tough Oakes and Wright-Hargraves mines.

The Tough Oakes company paid dividends amounting to \$260,750 in 1916.

PORCUPINE. Dividends paid by companies operating in this district during 1916 totaled \$4,180,750, to which the Dome contributed \$800,000; Hollinger, \$2,880,000; and Porcupine Crown, \$240,000. The total to date is \$8,920,000.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

DONALD F. IRVIN is here from Los Angeles.

C. E. KEYES, JR., of Oakland, is going to the Belgian Congo.

B. M. MCATEE spent the holidays in Denver and has returned to Miami.

RIENZI W. MACFARLANE is with the Arizona Copper Co. at Morenci, Arizona.

ARTHUR K. ADAMS has been appointed geologist to the Andes Copper Co. in Chile.

Ed. C. MORSE has gone to Rye Valley, Oregon, to take charge of the Rainbow mill.

N. H. RUBY, engineer at the Butters Salvador mine, has returned to Portland, Oregon.

N. O. LAWTON, general manager for the Vermont Copper Co., is on a trip through the West.

H. C. BAYLON has been appointed resident manager of the Spassky copper mine, in Siberia.

WILLIAM J. HAMILTON sails from New York on January 13, returning to Cerro de Pasco, Peru.

GEORGE ZOFFMAN sailed from San Francisco, on his return to Cinco Minas, Jalisco, on January 3.

JAMES NELSON, formerly superintendent of the El Favor mines, in Mexico, is at Salt Lake City.

HERBERT C. WOOLMER has resigned from the service of the Spassky and Atbasar copper companies.

ALF WELHAVEN, manager for the Oriental Consolidated Mining Co. in Korea, is sojourning at Los Angeles.

H. H. COLLEY has been promoted to superintendent of the Old Dominion mine and smelter at Globe, Arizona.

W. W. WISHON has been appointed consulting engineer to the Big Casino Mining Co., at Searchlight, Nevada.

A. R. WHITMAN, geologist to several mining companies at Cobalt, has returned thither after spending the holidays here.

J. C. RAY, who has been making a geological examination of mines at Oatman, Arizona, has returned to San Francisco for the winter.

C. A. FILTEAU has resigned as manager of the St. Lawrence Talc Co. to take the management of the National Mines, Ltd., Cobalt, Ontario.

MARK R. LAMB has resigned as manager in South America for the Allis-Chalmers Manufacturing Co., and will return to the United States.

A. S. WHEELER has resigned as Inspector General of Mines to the Chinese government and is visiting the Malay States on his way back to England.

JOSEPH W. RICHARDS notifies us by telegraph that he did not sign the circular issued by the friends of SIDNEY J. JENNINGS; it was JOHN W. RICHARDS of Denver.

JAY A. CARPENTER has resigned his position, as metallurgist for the West End Consolidated at Tonopah, to become general superintendent of the Nevada Packard Mines at Rochester.

The A. I. M. E. will hold its 114th meeting at New York from February 19 to 22, inclusive. About 50 members are expected to attend. The membership totals 5922, a gain of 200 since September.

The UNIVERSITY OF CALIFORNIA has issued its register for 1915-16, with announcements for 1916-17. This bulletin covers every phase of college activities.

The College of Mines of the UNIVERSITY OF WASHINGTON, at Seattle, held open house at the new experiment station on January 12.

THE METAL MARKET

METAL PRICES

San Francisco, January 9.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	35
Pig lead, cents per pound.....	7.75—8.75
Platinum, soft and hard metal, per ounce.....	\$85—91
Quicksilver, per flask of 75 lb.....	\$80
Spelter, cents per pound.....	13
Tin, cents per pound.....	41.50
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, January 9.

Antimony, 50% metal, per unit.....	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	15.00
Magnesite, crude, per ton.....	6.50—9.00
Manganese, 50% (under 35% metal not desired).....	16.00
Tungsten, 60% WO ₃ , per unit.....	18.00—20.00

Manganese remains unchanged, though considerable business is being done.

While the nominal price on 40% chromic iron is \$15, buyers are offering a premium on higher-grade ore. This premium is not fixed but varies with the quality of the ore.

The average price of tungsten in the Boulder district of Colorado during 1916 was a little under \$23 per unit. The output amounted to 2400 tons of ferberite concentrate. The present price is \$15 per unit.

New York, January 3.

Tungsten: The market is fairly active, but quieter than it was a week ago. Exports are restricted by the necessity of obtaining permits from Great Britain to ship.

Molybdenite: The market is quiet and easier, offerings of \$1.75 to \$1.85 per pound MoS₂ contained having been made.

Antimony: The quotation is nominal at about \$1.60 per unit.

EASTERN METAL MARKET

(By wire from New York.)

January 9.—Copper is dull, re-sale metal is easy; lead has remained quiet all week at 7.50c.; there is an evident effort being made to depress the price of spelter.

COPPER

Prices of electrolytic in New York, in cents per pound.

During November 1916 the output in pounds of several of the largest copper producers was as follows: Utah Copper, 16,421,192; Nevada Con., 7,047,486; Ray Con., 6,894,736; Chino, 6,906,024. In December the production of Chino was 4,622,273 lb. and of Inspiration Con., 10,400,000 pounds.

Inspiration Consolidated pays \$2 per share on January 29. Mohawk pays \$10 per share on February 1, and United Verde Extension pays 50 cents on February 1. Miami Copper Co. pays a dividend of \$2 on February 5.

During December silver was shipped from San Francisco to the amount of \$1,998,695. The total amount of bullion and coin, both gold and silver, shipped from San Francisco during 1916 was: coin, \$29,001,571; bullion, \$28,250,511, a total of \$57,252,082. Of this amount \$12,577,262 was in silver bullion. During December silver in ores and base bullion was imported at San Francisco to the amount of \$422,213.

Silver shipments from London to India from January 1, 1916, to December 6, 1916, reached a value of \$3,641,000, as compared with \$3,663,000 during the year 1915.

Dec.	33.60 38.71 42.55

Tin is strong at 42 cents.

ANTIMONY

In a quiet market Asiatic grades are quoted at 14.25 to 14.50c., New York. Despite the absence of demand, holders of the metal have marked up their prices a little.

ALUMINUM

No. 1 virgin aluminum 98 to 99% pure is unchanged at 60 to 63 cents.

Eastern Metal Market

New York, January 3.

With all the metals, the usual holiday quiet has been accentuated by a feeling of uncertainty which makes both buyers and sellers inclined to sit still and await developments.

The most important feature in copper has been offerings at concessions by second hands, including consumers. Metal for prompt delivery has appeared unexpectedly in several directions. The producers are holding firm, but selling little or no copper. The London market is weaker also.

Zinc is quiet and featureless, but prices have held steady.

Lead is dull, but firm.

Tin shows a stronger tendency, although buying has not been large.

Antimony has a firmer tone.

Reports are current that the Entente Allies have cancelled a number of munitions contracts in this country, and that new contracts will be distributed in Canada. This is logical in view of the extent to which Canadian manufacturers have been preparing themselves during the past two years to handle munitions work. The Canadian banks recently placed \$50,000,000 at the disposal of the Government for the purchase of munitions and supplies, making \$250,000,000 so loaned. In the last year Canada has purchased more machine-tools in the United States than in any previous year, and it is now declared that she is in a position to fill orders at the rate of \$400,000,000 yearly. Patriotism is sufficient to account for the placement of war orders in the Dominion to the maximum extent.

December pig-iron production amounted to 3,171,087 tons or 102,293 tons per day, against 3,311,811 tons in November, or 110,394 tons a day. Several furnaces were banked January 1, leaving 311 active against 322 December 1. The total production of 1916 is estimated at 39,450,000 tons. The previous high year was 1913, when 30,966,152 tons was produced. The 1915 production was 29,916,213 tons.

The pressure on the steel mills is as great as ever, but operations are hampered by transportation troubles which interfere with the delivery of raw materials and finished products.

COPPER

The copper market presents a rather uncertain aspect, which, if persisting, not even the producers can continue to view with equanimity, despite the extent to which they have sold over the first half of 1917. Reference is to the fact that in the past few days consumers and second-hands have been pressing copper for sale at concessions. It would seem, however, that the rebuff which the German peace proposition received from the Entente Allies would serve to stiffen the metal market, as it has done with certain war stocks on the Stock Exchange. Electrolytic was easily obtainable for January delivery yesterday (January 2) at 28.50c. First quarter was quoted at 28c. and first half at 27.50c. Lake is about 1c. higher than electrolytic. The London market has continued to decline, the quotation yesterday for spot electrolytic being £145 against £152, December 27. Of course, the market has been quiet in the past few days because of the holidays and the absence of cables from the other side. The offerings by consumers give rise to the disquieting suggestion that if prices continue to decline it may bring about a failure to take some of the metal under contract. This is in the minds of a portion of the trade which, however, may be ultra-conservative. It may be repeated that it is deliveries and not orders which count. Meanwhile the producers have no early copper to sell and are merely watching the market. The peace talk has had its effect on the larger sizes of brass rods which are much used in munitions work and they are easier around 33c., mill. Other brass, and

also copper, products, such as sheets, tubes and rods for industrial use are as strong as ever, sheet-copper being quoted at 42c. to 43c., delivery at mill convenience. Tubing is exceedingly difficult to obtain. The figures of the U. S. Geological Survey estimate the smelter production of copper in 1916 at 1,928,000,000 lb., against 1,388,000,000 lb. in 1915, an increase of 540,000,000 lb. The December exports totaled 22,682 tons.

ZINC

For over a week the market has been quiet, but prices have been steady. In the last few days of 1916 a fair business was done for first-quarter shipment at 9.50c., St. Louis, or about 9.75c., New York. For the first half, 9.25c., St. Louis, or 9.50c., New York, has been done. The brass trade has been doing but little buying. With zinc, as with copper, the market has been a waiting one. It is admitted that the course of prices depends very largely on the export demand. Should this fail, it leaves the opportunity for surplus stocks to hammer the market down. Producers' representatives who predicted 14c. spelter in January now have but little to say. A favorable turn may be given to the market by the preliminary figures on production in 1916 as announced by the U. S. Geological Survey. The 1916 production from domestic ores is estimated at 553,000 tons, against 458,135 tons in 1915, an increase of 94,865 tons. From foreign ore 105,000 tons was produced in 1916, against 31,384 tons in 1915, making the total for 1916, 658,000 tons, against 489,519 tons in 1915. The interesting fact in connection with the figures is that production is estimated to have been far below where it was placed by predictions made in 1916, which served to depress the market. In April it was pointed out that existing and contemplated capacity would make possible a production of 800,000 tons a year. Early in December it was announced by an authority that existing capacity was sufficient to produce at the rate of 761,000 tons a year. Yet the estimate of the Survey places the total 1916 production at 658,000 tons. The December exports totaled 6628 tons. The London quotation for spot yesterday (January 2) was £50 5s. against £51 10s. December 27. Sheet-zinc is unchanged at 21c., f.o.b. mill, carload lots, 8% off for cash.

LEAD

The week has been quiet with prices practically unchanged, but steady. The independent producers quote 7.50c., New York, and about 7.35c., St. Louis. The leading interest continues to quote 7.50c., New York, but it is well understood that when it sells, settlement must be on the basis of its average quotations. More business could have been done in the past week had more chemical lead been available. The U. S. Geological Survey estimates the total 1916 production at 579,600 tons against 550,055 tons in 1915, an increase of 29,500 tons. The December exports totaled only 308 tons. The London quotation for spot January 2 was unchanged at £30 10s.

TIN

On December 27 a good business was done, between 300 and 400 tons changing hands. On the surface the market appeared very quiet on that day, the reason being that the selling was practically confined to two houses. On December 28 and 29 about 200 tons was taken. An interesting event which occurred December 29 was a sale "under the rule" on the floor of the N. Y. Metal Exchange, of 100 tons, presumably because of a dispute over a contract. For 50 tons of March delivery 40.62½c. was paid, and for 50 tons of April, 40.70c. The market stiffened yesterday (January 2), spot selling at 43c. The deliveries into consumption in December were good, amounting to 4082 tons, 1282 tons of which came via Pacific ports. In stocks and landing January 1 was 3511 tons; on the 2nd the quantity afloat was 3961 tons.

Industrial Notes

Information supplied by the manufacturers.

Self-Rotating Hammer-Drill

The Wood Drill Works, of Paterson, New Jersey, has just placed on the market a self-rotating hammer-drill that also automatically cleans the hole. If by any chance the air going through the steel is not sufficient to clean the hole, in some kinds of rock, by pressing down the button at the top of the chest, the full pressure of air is directed to the drill point, cleaning the hole of all cuttings at once. By releasing the

SECTION OF SELF-ROTATING HAMMER-DRILL.

button the drill starts automatically. One of the advantages of this drill is the absence of piston breakage; another is, no collars are required on the steels, eliminating a great deal of blacksmith trouble and expense. The hollow piston always strikes squarely on the anvil-block. The steel only requires to be cut-off squarely and tempered, and pushed up against the anvil-block of the drill. The cylinder and chest is made of vanadium-tungsten iron. It is self-oiling, and has soft rubber grips on the handle that reduce the vibration on the operator.

The San Francisco office of the DU PONT COMPANY has sent us a circular giving the advance in price of B blasting-powder, effective January 1, in California and Nevada. For less than 10-keg lots the price is \$1.95 per keg; for 100 kegs, \$1.70 per keg; and for car lots (800), \$1.50 per keg. On the 4F granulation, the price is \$2 for less than 10 kegs, \$1.75 per 100, and \$1.55 each for car lots.

Having purchased the plants of the U. S. Reduction & Refining Co. at Colorado City, Canon City, and Florence, MORSE BROS. MACHINERY & SUPPLY Co. has prepared a special stock list of the machinery and apparatus in these works.

The YUBA CONSTRUCTION Co. reports that Mark G. Evans of Denver just placed an order for an 8-cu. ft. dredge, electrically operated, and digging 65 ft. below water-level, for a property near Breckenridge, Colorado.

EDITORIAL

T. A. RICKARD, Editor

THE scarcity of cyanide is compelling mill-men in the United States and Mexico to ascertain whether they cannot substitute flotation in place of cyanidation in the treatment of gold and silver ores.

WHAT zinc mining has done to make men rich is indicated by the record of the New Jersey Zinc Company in 1916. Last year \$26,600,000 was distributed in dividends; of this two shareholders drew over \$2,000,000 each and three others received over \$1,000,000 apiece.

ACCORDING to Government statistics the United States produced 2,311,000,000 pounds, or 1,155,500 tons, of copper in 1916. This includes metal smelted from imported ores. The domestic production was 964,000 tons. This compares with an American production of 612,500 tons in 1913 and a world's total output of 1,100,000 tons in the year before the War.

DIVIDENDS from the gold mines of the Rand show a further decrease for 1916, the total being £7,139,386, a diminution of £500,000 as compared with 1915. In 1909 the total of dividends was £9,523,500. The decline is due in part to the War, which has increased the cost of supplies and machinery, but it is due mainly to the impoverishment of the mines as they become deeper. The logic of facts is incontrovertible.

DOMESTIC production of lead in 1916 was 324,000 tons of desilverized lead and 234,200 tons of soft lead, making a total of 558,000 tons, worth \$75,915,000. The production from imported ores was 21,400 tons. Imports were 35,800 tons and exports 117,550 tons. The average price was 6.8 cents per pound, as against an average of 4.7 cents in 1915. In 1913 the domestic lead production was 436,430 tons.

REFERRING to the duration of an American patent that is a duplicate of a British patent, a change in the law was made in 1897. Prior to that year United States patents expired when the first corresponding foreign patent came to an end. In 1897 the law was changed so as to give the American patent its full 17 years, instead of the 14 years or less that it had previously. The law became effective as to all applications filed after January 1, 1898.

WHILE on our way home in the evening many of us have lingered to watch the driving of the piles, 115 feet long, that are preparing a foundation for the Southern Pacific Railway company's new building. What makes it so fascinating to watch a pile being driven into

the ground? Is it not the conquest of mind over matter — of a machine directed by intelligence overcoming the inertia of a senseless piece of timber? To us also there came back Ambrose Bierce's remark about persons whose understanding "is like a pile driven into the mud, the more you hammer it with fact the less there seems to be of it."

ANOTHER big mine of the disseminated-copper type is reported as being in course of development, not in Arizona, but in Siberia. It is in territory controlled by the Irtysh Corporation and near the Ekibastous coal-field, where that company has engineering shops and other necessities for rapid exploratory work. This district is part of the Altai region. Among the engineers mentioned in connection with this important prospect is Mr. R. Gilman Brown, formerly well-known in San Francisco.

ANACONDA made a new record of production in 1916, supplying the world with 336,900,000 pounds of refined copper, of which all but 24,000,000 pounds came from the company's own mines. Among the new producers Chile Copper yielded 6,118,000 pounds in the month of December, but rapid expansion of output is hindered by lack of shipping facilities. This company's Chuquicamata mine was expected to be producing ten million pounds by 1915, and it may attain that figure during the coming summer. Three or four years more are likely to pass before another 10,000,000 pounds is added to the monthly production.

GEOLGY is a science that lends itself to the constructive imagination. That may be one reason why we are given so many "delirious trimmings," as the old lady said. For instance, in the columns of our learned 'contemtuary' at New York we read that "during the Devonian and Carboniferous ages great beds of limestone were deposited conformably on top of the sandstone" and that "the first faulting occurred during pre-Cambrian times, faulted the schists, diorites and enclosed orebodies, but not the overlying strata and lavas." It is gratifying to learn from a 'savant,' as the daily press would label him, that a valuable part of the earth known as the Jerome mining district was saved from so painful an experience as having its Devonian sediments dislocated during pre-Cambrian time.

LACK of cyanide has compelled the Santa Gertrudis company, at Pachuca, to suspend milling operations. At the recent annual meeting, the chairman, Mr. F. W. Baker, explained that no cyanide could be obtained from

Germany for obvious reasons: the American market is closed because that market "is mainly supplied by a German house now on the black list," and the English—chiefly Scottish—supply is diverted by Government enactment to the gold mines in the British dominions. In consequence of this inability to procure cyanide, the metallurgists of the company are making tests with flotation, with a view to recovering the silver in a concentrate that will be saleable to the Mexican smelters. We hope that those smelters will not be put on Villa's black list. The flotation tests have given good results. Thus does the Great War affect metallurgical development. Incidentally, we note, with pleasure, that the directors voted a bonus of \$5000 to Mr. Hugh Rose, the manager, "in recognition of his untiring efforts and the excellent work performed by him during the very trying conditions that have existed in Mexico for several years past."

STATISTICS of gold and silver production are given on another page. The output of gold in the United States during 1916 is estimated to have decreased \$8,719,300 as compared with 1915, while the output of silver decreased in quantity by 2,077,275 ounces but increased in value by \$10,560,000, the average price of silver having been 65.8 cents in 1916 and 49.69 cents in 1915. In gold production California is again first, Colorado second, Alaska third, and South Dakota fourth. Only California produced over a million ounces. The production of South Dakota comes mainly from one mine, the Homestake. Montana is first as a producer of silver, Utah and Nevada are a close second, and Idaho is fourth. The by-product silver obtained from copper ore is an important factor in the output of silver in Montana, Arizona, and Utah. The silver of Idaho comes chiefly from lead ores. Tonopah, in Nevada, is still the most important producer of primary silver. Five States (including Alaska) contribute 80% of the gold production and four States contribute 55% of the silver. Nevada is included in both groups.

SUGGESTIONS of non-persistence of ore in depth, that is, impoverishment of mines as they become increasingly deep, have been good-naturedly derided by those directing operations in the Kolar goldfield. It is interesting to note that at the recent meeting of the Champion Reef Gold Mining Company a melancholy note of warning is sounded. "Decrease in values," meaning gold contents, is acknowledged and "any marked improvement in the mine" is said to be "hardly to be expected yet." Thus shareholders are soothed with the hope that a 'zone' of richer ore may be cut still deeper, in optimistic disregard of the fact—well known, of course, to the management—that the orebodies in the Champion Reef pitch downward from the adjacent mine—the Mysore—in which there is no evidence of lower orebodies that will enrich still deeper workings in the Champion Reef. Unless new and deeper orebodies are found in the Mysore there will be no still deeper orebodies to be worked in the Champion Reef. The Indian mines, of which only four are now active, all on the same

lode, have been thriftily managed and will pay dividends for many years, but it is curious how the salient fact of impoverishment has been disregarded so long.

The Use of Flotation

The Minerals Separation company advertises that "a settlement for past infringement must precede granting of licenses for future use of the process" and that it "will enforce its patents and stop all infringements." By virtue of its ownership of U. S. patent No. 835,120, the validity of which has been upheld recently by the Supreme Court, this company is in a dominating position. A patent is property; the patentee can withhold his license to use the thing patented; he can levy what royalty he pleases; but he may find difficulty in collecting it. No direct law exists for regulating such exactions. In Canada an appeal can be made to the Commissioner of Patents against any unreasonable royalty and only a charge established by precedent can be imposed successfully; if the patentee is too grasping his victim goes to the head of the Patent-Office and he appoints a commission to adjudicate. Minerals Separation may decide to be rough with those they regard as infringers, but the latter can make the most of the law's delays. One would suppose that the Anaconda-Inspiration contract with Minerals Separation might serve as some sort of guide in establishing a royalty on copper ores, at least. We published the text of that contract in our issue of September 16, 1916. The royalty specified in that agreement is from 12 cents per ton on less than 4000 tons daily to 4 cents per ton on more than 30,000 tons, but there is a curious proviso that on the 5000 tons in excess of the first 10,000 tons—up to 15,000—there shall be no royalty, so that the royalty on 15,000 tons daily is only 6 cents per ton. Unfortunately the courts take little cognizance of any contract except the one at issue. The patent is held to afford presumption that the process is valuable. Mr. Ballot and his friends believe that their enemies—for so they regard the infringers—are delivered into their hands. The independent users of a process developed by a long series of improvements made by many men refuse to accept the implication of infringement and are as determined as ever to contest the monopoly claimed by Minerals Separation. How this can be done, we shall suggest.

Turning to the decision of the Supreme Court, delivered on December 11, 1916, we find a precise definition of the process covered by patent 835,120. Stress is laid on two limitations: (1) the agitation is obtained "by beating air into the mass" of ore and water, and (2) the use of a 'critical' proportion of oil, namely "a fraction of 1% on the ore." The Court says of the patentees that "while the evidence in the case makes it clear that they discovered the final step which converted experiment into solution, 'turned failure into success,' yet the investigations preceding were so informing that this final step was not a long one and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the

claims of the patent as 'critical proportions' amounting to a fraction of one per cent on the ore, and therefore the decree of this court will be that the patent is valid as to claims No. 1, 2, 3, 5, 6, 7, and 12, and that the defendant infringed these claims, but that it is invalid as to claims 9, 10, and 11." The three claims last designated do not mention a specific quantity of oil; they refer to "a small quantity" of it. Clearly the patent is held down to the limitation of "a fraction of 1%"—that is, less than 20 pounds of oil per ton of ore.

The fact is overlooked, by the Supreme Court and others, that the agitation-froth method was based upon the use of oleic acid in experiments on Broken Hill ore. Oleic acid is a thick oil and the Minerals Separation metallurgists recognized early that any excess of it in the pulp tends to coagulate the metallic particles into flocks so as to make them sink. The patentees of 835,120 assumed incorrectly that what was true of oleic acid was true of all oils. Since 1905 a great number of oils, of a character quite different from oleic acid, have been brought into use for the purpose of flotation.

We are able to state that 21 to 22 pounds of oil per ton of ore is now being used in several mills, notably the Arthur plant of the Utah Copper Company, without any diminution of metallurgical efficiency as compared with the smaller proportion used previously. The recovery is 88% and the tailing assays 0.12% copper. This result is being obtained on vanner-tailing, and even better flotation work is being done on low-grade vanner-concentrate. More of the cheaper kind of oil and less of the expensive kind is used, so that the extra cost is not excessive—it is within the limit of the average royalty that Minerals Separation collects from its licensees. Another interesting point is the amount of oil in circuit in a flotation plant. While two or three pounds may suffice for an experiment in court or in the laboratory, it is necessary to use many times more in the course of a working metallurgical process, so that "the fraction of 1% on the ore"—meaning dry ore, not watery pulp—becomes quite a different ratio when conducting a complete cycle of operations in a mill. In short, the amount of oil used and necessary to use in a flotation mill is many times the amount lost or consumed in the series of operations viewed as a whole process. These suggestions may prove helpful to some of our readers. There are 234 so-called infringers in the United States. They can ascertain for themselves whether they are indeed working the process inside the definite limitations set by the Supreme Court. The measuring of the oil in a pulp can be done by use of a centrifugal separator or the oil in a sample can be dissolved in ether. The expulsion of the oil by heat and the condensation of it afterward complete the test. A simple and effective method for this purpose is required and is sure to be devised without delay.

The Supreme Court limited Minerals Separation to "a fraction of 1%" of oil, and the Court also defined the process of patent 835,120 as one in which aeration of the pulp is done by "beating air into the mass," as is done by an egg-beater or a blade-impeller, but not by the quiet passage of air admitted through a porous bottom, a per-

forated pipe, or in similar ways. This would seem to exclude the pneumatic machines of the Callow type from the restrictions of the patent. Moreover, the Court defined the mode of agitation used by Minerals Separation as "greater than and different from that which had been resorted to before." Again, we have heard a great deal about the persistent, coherent, and miraculous froth that Minerals Separation, and only they, produced. They are held to their own disingenuous assertions. In effect, the Court says: "You present the assumption, which the evidence of the defendant has not disproved, that you produce a particular kind of froth when a specific proportion of oil is added to pulp agitated violently by a mechanical stirrer. All right, gentlemen, we grant you a patent within the limits stated by yourself, and you are welcome to make the most of it." It looks to us as if the decision might have a citric flavor, possibly now, more probably when the Miami suit comes before the Court of Appeals at Philadelphia. The Supreme Court gives Minerals Separation its pound of flesh, but no more; the company is held to just that pound, as nominated in the bond of 835,120. "An upright judge, a learned judge!"

Taxing Mines in London

In days that older members of the profession can recall, the London market played an important part in American mining, because it furnished the means of selling and floating many important mines. In later years the wealth accumulated at New York, Boston, and other commercial centres in the United States has sufficed to energize mining operations on the largest scale known to the modern world. However, London was a great distributing centre for the capital engaged in mining up to the days—now seeming so distant—before the beginning of Armageddon. The question arises whether one of the effects of the War may not be the impairment or even the destruction of the facilities heretofore afforded by London for the promotion of mining enterprise. From the information at our disposal we are compelled to consider the outlook unfavorable, if not gloomy. The extraordinary taxation incidental to the War is serious, for an income tax of 5s. in the £, or 25%, is unpleasant, especially to shareholders that are not citizens of the belligerent country in which this tax is levied. It is sufficient to deter Americans from wishing to register a company at Somerset House or to have the headquarters of a company on London Wall. Hitherto the free market for shares offered by the London Stock Exchange has been an inducement to give British domicile to an Anglo-American mining company. How long a 25% income tax will continue to be imposed and whether it may not be increased to a higher proportion, as it already is for those liable to super-tax, nobody knows. If the War should be unduly prolonged, this means of raising revenue is likely to be employed increasingly, and even after hostilities cease it is probable that no immediate diminution of the tax is to be anticipated until some of the financial burdens of the War have been liquidated.

To an American, therefore, the holding of shares in a mining company registered in London is not likely to be pleasant and the flotation of mines on the London market is not likely to be attempted. Again, the companies operating mines in South Africa, Australia, Canada, or in other British dominions, have had to protest against the payment of a double income tax, when their headquarters are in Great Britain and the mine is in one of the overseas dominions. Some measure of relief has been given to such companies by allowing British shareholders a rebate equal to the amount of the colonial income tax. If, however, the only question were that of the income tax, serious as the burden is, we might be disposed to think that the effect on the mining business of London might be temporary. There is a worse deduction: the excess-profits tax. Broadly speaking, this amounts to 60% of the surplus profit above the average pre-War standard. Where no pre-War standard exists the Act provides for a 'datum line,' as it is called, of 6%, above which this tax becomes effective. It also provides that where such a return of 6% may, for any cause arising out of the particular nature of the business, be regarded as insufficient, a higher datum line may be fixed by a board constituted *ad hoc*, known as the Board of Referees. Shortly after this Act was promulgated a belated effort was made to persuade the Treasury authorities that it was unfair and extortionate. The Institution of Mining and Metallurgy took the lead in making an organized protest by means of a representative committee, and 93 companies domiciled in Great Britain, with an issued capital of \$280,000,000, subscribed to a preliminary guarantee fund to meet the necessary expense. It became apparent that the first thing to do was to establish a datum line for the whole industry of metal mining—excluding coal and iron. The real trouble is not so much the amount of the tax, although 60% plus income tax comes perilously near confiscation, as the utter capriciousness of its incidence. A company starts work in 1908 and attains its maximum output in 1914; this company pays no excess-profits tax. Another company starts work a little later, begins to make a profit in 1914, and gets into its full stride in 1916. This company pays the bulk of its profit to the Government, although its property is situated in South America and is only registered in London because it was believed that the English laws would give some protection. A third company, exactly in the same position as the second, that is registered, let us say, in South Africa, pays nothing on its excess profit. In other words, a mining company is penalized for being registered in London. Of course, examples of an even more grotesque injustice could be quoted. For instance, the Taquah company, operating in West Africa. This company, for reasons into which it is not necessary to go, allowed its development to get badly in arrears; it had to borrow \$500,000, run its mill on half-time, and devoted itself mainly to exploratory and development work. Unfortunately this was done in 1912 and 1913, and it was not until 1914 and 1915 that it began to enjoy the fruits of a wise policy. Profits began to increase and the company was enabled to pay back the money it had bor-

rowed. Now, however, it is liable for excess profits, although the profit it is earning is rather less than it was in 1910. In other words, the incidence of this excess-profits tax is largely fortuitous.

Obviously no company whose mine is in a foreign country will be willing henceforth to register in Great Britain unless the tax laws are modified. Already some of them have made a change of domicile. Even from the British point of view as expressed in letters received by us from London, it is felt that the tax on mining companies will yield comparatively little and prove of no consequence in financing the War. It affects only those that are registered in England and happen to have increased their production since 1914. These constitute a mere handful. Those whose property is in the United Kingdom cannot run away and must take their medicine, but the much larger number, situated in South Africa, South America, and elsewhere abroad, over which the British government can exercise no effective control, can and will escape the impost.

The Board of Inland Revenue and others responsible for this condition of affairs may not be directly concerned with the effect of this tax upon mining, which is treated by those in authority as the Cinderella of the imperial household, yet it is opportune to remind them that the mineral explorer was the pioneer of British expansion and that the prospecting for metallic ores was the original motive of British domination in Australia, South Africa, West Africa, Western Canada, and other large spaces now tinted red on the maps that hang in Whitehall. The Board of Inland Revenue is a synonym for all that is unsympathetic to human endeavor, but, if the matter is explained convincingly, even the mandarins of taxation might hesitate to kill the goose that lays their golden eggs. We are glad to know that the leaders of the mining profession, in England—the council of the Institution of Mining and Metallurgy—have bestirred themselves to bring the matter before the public and more particularly before those that have the say in fiscal affairs. They have begun by enunciating one or two axioms: (1) that mining is necessarily hazardous and that 15% is the minimum rate required to render profitable the use of capital in mining enterprises; (2) that a mine is a wasting asset and that an investor is entitled to a return of his capital during the life of his mine, and that therefore an amortization percentage should be added to the 15% specified above; (3) that the life of each individual mine be determined by dividing the estimated ore reserves by the annual rate of production. It is a pity that some of these axioms were not drilled into shareholders in the days before the great unpleasantness, for it must be confessed that the tax-gatherer has obtained many of his weird ideas of mining economics from the speeches of chairmen of mining companies when distributing verbal flummery to simple-minded shareholders. War is a severe teacher. We hope the lesson will be taken to heart, for, far as San Francisco may be, we speak for many of our readers in regretting any permanent injury to the London mining market.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Electrolytic Zinc at Trail

The Editor:

Sir—Permit me to correct one or two statements appearing in your issue of December 30.

In the only interview I have had with you, on the evening of August 22, last, I was very particularly careful not to make the statement that our patents were being infringed by either the Consolidated company at Trail, or by the Anaconda company. At that time I had only the vaguest idea of what was being done at Trail, and the only really definite information I have at present is derived from your issue of December 30, and that of the previous week. Any other information was merely gossip, to which I have barely listened. With regard to the Anaconda company, I have informed them that under certain circumstances they would be infringing our patents.

The management of the Consolidated company had made the statement that some of our patents are not valid, and this it was that led me to say to you that I had not, at that time, completed my search of the patent records. Since that time I have continued my search, and have found nothing which does not confirm the validity of our patents. You will recollect, too, that I mentioned to you that German patents had been granted, which, in itself, is very conclusive evidence of the validity of our patents. I have already informed you, in the interview referred to, that I have not the slightest intention of allowing myself to be drawn into any discussion of our patents, or the principles of our process at the present time, nor of our relations with the Consolidated company. Again, our company did not secure a grant of \$40,000 from the Provincial Government of British Columbia. To be exact, the Government has guaranteed the debentures of our company to that amount, and has granted us the use, at a nominal rental, of the disused, but well-equipped, electric smelter which fell into its hands several years ago.

In reply to your remark that the Provincial Government, as a patron, should insist on publication of the fullest information, I may say that the late Premier, Sir Richard McBride, was quite cognizant of our treatment by the Consolidated company, and that I would not have accepted any help from the Government had they stipulated that details should be published.

In saying that Mr. J. O. Patenaude secured the Government grant previously referred to, you have been misinformed. Mr. Patenaude's help was very valuable, but he played only a minor part in securing aid from the

Government. To Mr. R. F. Green, the representative for the Kootenays in the Dominion Parliament, we are much indebted for invaluable help. To him mainly is due the credit for the aid we have received, on account of his insistent representations to the Provincial Government of the value of our process, and of our claims as the pioneers in the electro deposition of zinc, not only in Canada, but elsewhere.

Nelson, B. C., January 3.

THOS. FRENCH.

The Editor:

Sir—In your issue of December 30, the editorial on electrolytic zinc at Trail seems to infer that I had to do with designing the plant. The credit of this is entirely due to Mr. R. H. Stewart, Mr. Blaylock, and Mr. Guernsey, and the able staff.

I can bear testimony to the enormous difficulties overcome in bringing the plant to the operating stage in 11 months, during a period when material, machinery, and men were so difficult to obtain, and while most of the building operations were carried on in the severest winter of many years. The top of the 200-ft. stack was housed and warmed to prevent the material from freezing. Men were hard to get, as one-twelfth of the whole population of the province had volunteered and gone to the front. This included practically all of the unmarried engineers, chemists, and better class of mechanics.

Trail, B. C., January 4.

Mining Law Revision

The Editor:

Sir—In your editorial note of January 6 you write, "we suggest that short of a general revision of the land laws by a competent commission, it is undesirable to repeal the extra-lateral right." Your opinion is shared by but few of those mining engineers who answered the questionnaire of the Mining and Metallurgical Society; more than 129 were in favor of doing away with the extra-lateral right "in so far as any claims hereafter to be located are concerned" and only three engineers voted to retain the extra-lateral right. And I think that this is a representative vote. The whole subject has been so fully discussed that it seems useless to give any arguments here. Dr. R. W. Raymond, in his articles in the Transactions of the Institute and in the technical journals has said about all that is needed for a full understanding of the question.

While I fully agree with J. T. Wilkins (M. & S. P.,

January 6, page 10) that a "wagon-load or so of judicial legislation shows us where we are at;" yet I do not agree that it is a good place to stop. I think that the sooner we do away with the extra-lateral right the better; if the revision of the mining law does no more than eliminate the extra-lateral right it will be quite worth while. Extra-lateral rights raise a series of problems that are absolutely unsolvable by the human intellect. As a result it is always easy to find learned professors and practical engineers who can find plenty of facts to prove the theory that suits their side of a lawsuit. And the uncertainty of the law is probably never greater than in a lawsuit involving extra-lateral right. Hence most mining engineers believe in vertical boundaries. And it is a credit to the Mining and Metallurgical Society to have obtained the expression of opinion in the vote quoted above. Let us honor those who try to do a good work and not sit on the fence and throw stones at them.

Palo Alto, January 9.

W. H. SHOCKLEY.

Fighting Mine-Fires

The Editor:

Sir—The paragraph in 'Concentrates' of September 23, regarding the fires in the United Verde mine, conveys, if you will permit me to say so, erroneous impressions regarding the fire-fighting system. As I am the one who inaugurated the positive plenum system and operated it, at the United Verde, for over four years, I feel justified in briefly stating the reasons for the method as used so successfully, for the benefit of your large number of technical readers.

In the first place, before I undertook the work of fire-control there, I secured all the data possible as to the prior history of the oldest fire-zone, that in the Wade-Hampton ore-horizon. From this information, I can state that the character of the ore, though 'accessory after the fact,' had little or no bearing as to the direct origin of the fire. The fact is that 22 years ago the mining of extremely wide orebodies, such as obtain in the United Verde (one of them being nearly 500 ft. between walls), was by no means as well understood as in more recent times. These wide bodies were mined by the square-set and fill method; the filling did not keep pace with the mining, and after raising up from three to seven floors the arch of ore broke and the friction of the massive chalcopyrite with softer oxide ores caused spontaneous combustion; the sulphur content ranging from 33 to 38%. The fire condition obtained and in that day of natural ventilation the only recourse was to bulkhead the fire-zone, in the vain hope that the fire would ultimately exhaust itself. The soft and highly pyritic ores no doubt aggravated fire conditions but did not primarily cause them.

In the second place, the air pressures are not primarily maintained for the purpose of forcing back the gas to cool the ground so that work may be done, but absolutely and primarily for the purpose of killing the active combustion in the ore. Knowing that the chief product of

the combustion of a pyritic ore is SO_2 and that this gas is as thoroughly extinctive in character as CO_2 , I was satisfied that, by a properly regulated positive plenum system of ventilation, the SO_2 gas could be forced back on the zone of active combustion and the fire be extinguished by its own products of combustion. The success of the method has certainly shown that the theory was fairly well founded. Incidentally, the gases were held back and to a very superficial extent the ground was cooled. To what a limited extent the cooling effect progressed may be readily understood when I state that I frequently took temperatures in the ore up to 1100°F . As fresh faces of ore were broken, of course the cooling effect was progressive. We exploded dynamite in ground when the temperature was as high as from 550 to 650° . It was necessary to carefully balance the air pressure, which ranged from $\frac{1}{2}$ to $1\frac{1}{2}$ in. of water-gauge, depending on stope conditions. This, in brief, is a description of the fundamental principle of the method of fire-fighting in sulphide orebodies as I used it at the Iron Mountain mine, in Shasta county, California, and at the United Verde mine at Jerome, Arizona. I could burden your readers with a description of serious mining problems that arose and the effect both mental and physical on the men who were employed and the interested employers.

JOSEPH J. SHAW.

Arroyo, Masbate, P. I., November 7.

DRIVING in the Roosevelt Tunnel in the Cripple Creek district is advancing at the average rate of 5 ft. 7 in. per round of holes fired. The adit is 9 ft. wide and 8 ft. high and it requires 30 holes to the round. Little timber is required; the rock is hard—firm andesite-breccia—but water pours into the adit from every crack and crevice, the amount flowing out of the tunnel now being 10,300 gal. per minute. A drain at one side in the bottom of the adit is 4 ft. wide and 2 ft. deep. Recently 437 ft. was made during one month, working three shifts of eight men each. The adit is now in four miles from the portal and the rock broken in the face is hoisted through the Elkton shaft. It is the present intention to continue this great drainage adit to a point under the Golden Cycle shaft, 6400 ft. farther. The Golden Cycle mine is on the opposite side of the mountain from the Elkton. The adit will be about 2000 ft. below the surface at the Golden Cycle, and is expected to drain the entire group of mines in that vicinity, thus greatly prolonging the life of a number of important properties.

FINAL FIGURES, covering the 1916 operations at the San Francisco Mint, show that there was received a total of 4,213,510.773 oz. of gold—of which 1,549,318.833 oz. was Australian bullion and British coin—and 3,616,011.34 oz. of silver—of which 2,089,881.05 oz. was coin for re-coinage. Gold bars sold weighed 908,358.875 oz. There were 52,322,500 gold, silver, copper, and nickel coins made, worth \$21,204,100; also 6,065,000 pieces worth ₱345,000 for the Philippines.

Cinnabar in the Sierra Nevada

By S. L. Gillan

An unusual and interesting discovery of cinnabar was made in April 1916, in Kern county, California—unusual because of its occurrence in granitic rock, and interesting because the cinnabar lode had been exposed to the eyes of prospectors for years and until the date mentioned had remained undiscovered. It is in Sec. 27, T. 31 S., R. 32 E., M.D.M., the section where the famous loop of the Southern Pacific railroad has been built through Tehachapi Pass. J. E. Hicks, of Tehachapi, was the discoverer, and he and W. N. Cuddeback are developing the property. Six men are employed and during the past month, a Johnson & McKay retort has been in use. The retort consists of a bench of 12 pipes and during the first 23 days, 18 flasks of mercury was produced. As the plant is new, losses are to be expected, but at the date of my visit the plant was producing one 75-lb. flask of mercury per 24 hours from two tons of ore. Cordwood, which is plentiful in this locality, is consumed in retorting at the rate of $1\frac{1}{4}$ cords per 24 hours. I have not made a detailed study of the geology of this region—merely a general examination. Granitic rocks prevail; in these are lenses of dark-colored mica-schist and dikes or masses of diorite, and about a mile east of the cinnabar discovery is a belt of Carboniferous limestone that can be traced for several miles in a north-west direction. The cinnabar is found in a light-colored altered rhyolite dike that is intrusive in granite. The dike in the vicinity of the shallow excavations made by Hicks and Cuddeback strikes east-west and dips north. It projects above the surface in a rugged outcrop; the granite hanging wall is well exposed by their main excavation in a canyon that cuts the dike. Down the canyon 300 ft. from the hanging wall, granite is again exposed. This dike is the largest of a series of approximately parallel rhyolite dikes and will be referred to as the main dike. Its thickness, where the canyon cuts it, measured at right-angles to the dip, is 150 ft. About 100 ft. north of the main dike another rhyolite dike, 45 ft. wide outcrops, and 350 ft. south of the main dike a third rhyolite dike, 60 ft. thick, is exposed. In a southerly direction from the last-mentioned dike other rhyolite intrusives are seen, their dips being to the north and north-east, their strikes varying from east-west to north-west. About one-half a mile south-west from the main dike is a belt of dark colored mica-schist. The zone disturbed by the intrusion of rhyolite dikes is 1000 ft. wide, and extends west and south-east from the place where the cinnabar is being mined. Another area of similar outcrops, presumably rhyolitic dikes, was reported by Hicks and Cuddeback to lie half a mile north of the one above described, but this was not examined by me.

The main dike is metamorphosed in places. It has been subjected to great lateral pressure, for the rock has a platy or laminated structure. It has been contorted also near the place at which it has been opened; the

plates dip vertically and are brittle. The groundmass of the rock is light colored and in it phenocrysts of opalescent quartz can be seen. This sheeting is common to all the rhyolite dikes. In a number of shallow surface excavations along the main dike, within a few hundred feet, cinnabar can be seen, some of it fairly high-grade—up to 40%, according to Mr. Cuddeback. At the time of my visit an open-cut exposed the dike for a width of 60 ft. Except in a 'horse' of barren rhyolite, an iron-stained decomposed rock that occupied an area in the face 15 ft. wide and 5 ft. high, the whole face of this excavation, 60 ft. wide and 5 ft. high, contained cinnabar. On the top, and on both sides of the horse, high-grade ore was seen. The cinnabar filled seams in the rock one-eighth of an inch wide and these seams were continuous for several feet in length. In other portions of the face the cinnabar permeated the rock and it gave it a pink color over areas of several square inches. It appeared to favor the softer, more altered, and porous portions of the dike.

The furnace on the property will serve as an experimental plant and is expected to provide means for continuing the development and exploitation of this interesting prospect.

Wet Treatment of Tungsten Ores

Ores of tungsten are treated by what is known as the soda process. This is usually carried out as follows: The finely ground ore is mixed with an excess of sodium carbonate and the mixture roasted in a reverberatory furnace, forming sodium tungstate. The charge is withdrawn from the furnace and ground in a ball-mill. From the grinding-mill the finely ground pulp goes to vats filled with boiling water, which dissolves the sodium tungstate; any impurities present lie on the vat bottom or float in suspension in the condition of slime. This material generally consists of iron, manganese, and gangue minerals. From the vats the sodium tungstate goes to a filter-press, from which the undissolved portions are removed. The solution passing out of the filter-press is treated with concentrated hydrochloric acid, which forms yellow tungstic oxide. This is removed, dried, and the powder mixed with pulverized anthracite, or carbon in some other form, placed in crucibles, and roasted, thus reducing the tungstic oxide to metallic tungsten, which is ground and washed to eliminate all remaining impurities, the tungsten then being in the condition of metallic powder, in which form it is used by manufacturers of steel.

LIME PRODUCTION of the United States in 1916 totaled 4,150,000 tons, an increase of 15%. This is the first year in which the output exceeded 4,000,000 tons. Pennsylvania led with 1,037,000 tons, followed by Ohio with 529,000 tons, Virginia with 350,000 tons, down to Tennessee with 120,000 tons, these being the States that yielded over 100,000 tons.

The Nickel Plate Mine and Mill

By T. A. Rickard

At Hedley, in British Columbia, a gold-bearing arsenopyritic ore in limestone has proved the basis for a highly profitable mining enterprise. The mine was discovered by two Englishmen, F. H. Wollaston and C. H. Arundel, who located four claims in 1898. The earliest location on the mountain was made by Pete Scott, who was grubstaked by Robert R. Hedley, a well-known Canadian mining engineer, formerly manager for the Hall Mines company at Nelson. His name was given to the original camp on Twentymile creek where it joins the Similkameen river. Wollaston and Arundel took some specimens of the ore to the Provincial Fair at New Westminster, where they were seen, while on exhibit, by M. K. Rodgers, an enterprising engineer whose name appears in the early story of several important British Columbian mines. Mr. Rodgers was scouting for the late Marcus Daly and was sufficiently impressed by the samples of ore to go to Hedley and inspect the prospect. After an examination

MAP OF PART OF BRITISH COLUMBIA.

he took a bond on the property for Marcus Daly. The price was \$60,000 and the date November 17, 1898. The four claims then bonded were the Nickel Plate, Bulldog, Sunnyside, and Copperfield. Exploratory work was started in the January following, and exposed enough ore to warrant the completion of the transaction on December 19, 1899. The remainder of the Nickel Plate property, covering 440 acres, was acquired by purchase and location during the following three years in the name of the Yale Mining Co. In 1912 the adjoining Windfall group of 200 acres was purchased by the reorganized corporation, called the Hedley Gold Mining Co., the control having passed, in August 1909, from the Daly estate to a group headed by W. E. Cory, W. D. Thornton, C. D. Fraser, I. L. Merrill, and Chester A. Congdon—all Americans. This deal was promoted by T. Walter Beam on a report made by Walter H. Wiley, and on the further advice of I. L. Merrill, who is now the president of the company. W. B. Dickson, of the Midvale Steel Co., is the vice-president.

An important part in the history of the mine has been played by Gomer P. Jones, an Australian engineer, who

came from Bendigo to New York in 1892. In August 1900 he was engaged as mine foreman by Mr. Rodgers and in August 1909, when the new company came into possession, he was appointed general superintendent, a position that he still retains, so that he has been connected with the management of the Nickel Plate for 16 years. Always full of faith in the successful develop-

THE STIRRING MECHANISM OF THE DEVEREUX AGITATOR.

ment of the mine, through all its vicissitudes, Mr. Jones has combined the instinct of the miner with a useful store of practical knowledge, so that he has retained the confidence of those in control throughout the changes of ownership and has had the proud satisfaction of seeing the Nickel Plate become one of the best known and most productive gold mines in British Columbia.

The economic geology of the district is the subject of an excellent report* written by Charles Camsell for the

*The Geology and Ore Deposits of Hedley Mining District. Memoir No. 2. Completed in June 1909; published in 1910.

Canadian Department of Mines. As early as 1877 G. M. Dawson gave the name of Striped Mountain to the high bluff on which the Nickel Plate mine is situated. Dr. Dawson attributed the banded appearance to the alternation of differently colored beds of limestone, quartzite, and slate; he overlooked the intrusions of igneous rock, which, by weathering to rusty brown, contribute more to

been highly metamorphosed, with the production of garnet, epidote, diopside, and tremolite, and the introduction of arseno-pyrite and axinite. The presence of gold in the arseno-pyrite, or mispickel, of the contact-metamorphic zone has been the means of creating rich orebodies.

The orebodies lie in overlapping succession, or *en*

NATURAL SECTION SHOWING SILLS OF IGNEOUS ROCK BETWEEN BEDS OF LIMESTONE.

the striped appearance than the sedimentary beds themselves. The ore-bearing formation consists of beds of limestone and quartzite, probably of Carboniferous age; these have been intruded by dikes and sills of diorite and gabbro emanating from a grano-diorite batholith, the top of which is exposed at the foot of the cliff near the mill. All the sedimentary rocks, but more particularly the limestone in the ore-bearing zone, have been changed by the metamorphism caused by the intrusives. The ore-bearing zone consists of a series of thin and relatively permeable beds of limestone, so penetrated by dike-rock of the gabbro phase that the calcareous matter has

echelon, in the limestone, but cutting across both the dip and strike of the containing rock; Mr. Camsell says that the dip of the orebodies "is dependent on the dip of the gabbro intrusive, which forms the foot-wall. The orebodies have no apparent connection with fissures, and are not always governed by the stratification of the sedimentary rocks."

I saw the orebody in the Nickel Plate workings; it lies close to the unaltered or less silicified limestone as a foot-wall. The roof, or 'hanging,' is a much silicified limestone divided by intercalations of the so-called 'andesite.' This is the term used by the engineers at

the mine. What the correct petrographic term may be—whether 'gabbro' or 'andesite'—is less important to the miner than the fact that this particular kind of rock is associated with the finding of ore in the locality. Mr. Jones informs me that the distance from the ore-channel to the grano-diorite is 2000 ft., the interval being occupied by the limestone of the Red Top formation, with interbedded quartzite, argillite, tuff, and breccia. The Nickel Plate formation, above the Red Top series, consists of a number of thin beds of limestone and quartzite, and it is to the association of these two kinds of rock of markedly different solubility that Mr. Camsell imputes the precipitation of ore. The enriched portion of the limestone—constituting an ore-channel—averages 120 ft. in thickness, with 200 ft. as a maximum. Ore has been found for a distance of 1500 ft. on the dip and the bottom of the mine is still in ore.

The foregoing refers more particularly to the parent mine, the Nickel Plate. Conditions in the adjoining Sunnyside workings are much the same, except that in the Sunnyside No. 2 a vertical tongue, 4 to 12 ft. thick, of gabbro penetrates the limestone and on the under side of this tongue the ore is found. In the Sunnyside No. 3 a similar condition obtains, another tongue, 12 ft. thick, appearing from below at an angle of 60°. In this case the ore is on the upper side of the intrusive. These tongues may be branches or apophyses from a stock and may have afforded a passage for thermal solutions. Various dikes cross the ore-channel, but they appear to be post-mineral.

In the No. 3 workings I noted the 'frozen' contact between the limestone of the ore-channel and the gabbro. The partings between limestone beds were lined with calcite; so were the joints. The orebodies appeared flatly lenticular and overlapping downward at an inclination about six degrees flatter than the dip of the containing beds.

Dip of contacts, 22° to 23° W.

Dip of orebodies, 30° W.

Pitch of orebodies, N 40° W.

The orebody in these workings has a maximum width of 300 ft.; a maximum thickness of 40 ft., with an average stopping width of 15 ft.; while the length on the dip is shown by the map to be 900 ft. This is the longest orebody yet mined. It extends from the outcrop to a point 100 ft. below the No. 4 adit. At No. 4 I saw the diamond-drill at work and subsequently Mr. Jones showed me the core, which, in the ore-zone, exhibited brown garnet, green epidote, drab diopside, greenish blade-like crystals of tremolite, and white calcite. The richer ore is found with the lime silicates—garnet, epidote—and calcite. When the limestone changes to chert, the core is impoverished. When the arseno-pyrite is well crystallized, it is poor in gold. The axinite indicates a high gold content.

The ore-zone is crossed by a broad band of fracture—50 ft. wide and brecciated—which does not displace the orebodies. It was formerly called Jones's fault—the only one I detected in that worthy gentleman—who informs

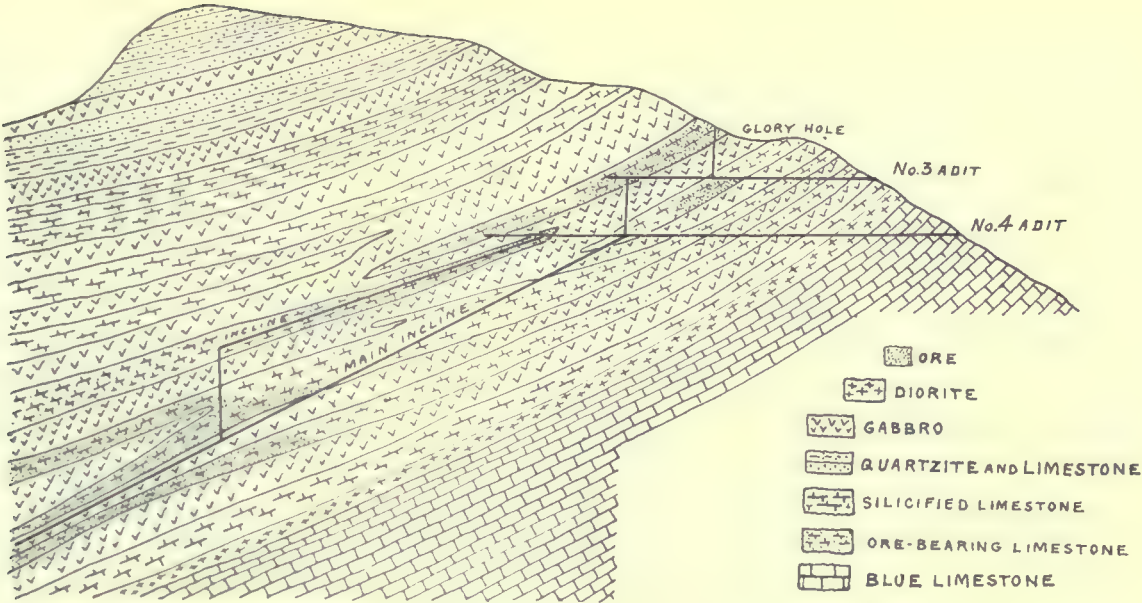

me that ore is found on both sides, so that this structure is probably post-mineral and is merely an unwelcome intrusion.

R. B. Lamb was manager during 1905 and 1906; he was succeeded by Frank A. Ross, who directed operations for three years, from 1906 to 1909, when Mr. Jones took charge.

The mill is not less interesting than the mine. The first reduction plant was started in 1902. It consisted of 40 stamps, 24 vanners, and a cyanide annex. In this plant 30% of the gold-saving was effected by amalgamation, 29% by cyanidation of the tailing, and 30% in a concentrate that was shipped to Tacoma. In November 1910 several changes were made in the mill, the chief of these being the discarding of amalgamation, because the proportion of gold recovered on the plates declined to as little as 2% of the total yield, owing to a decrease in the proportion of oxidized ore and a corresponding increase in the amount of arseno-pyrite associated with the gold. At that time the mill recovered \$43,000 worth of gold from 3900 tons of ore per month.

The drop of the stamps was increased from 6 to 7½ inches, and the speed from 90 to 106 drops per minute. The screen was changed gradually from 24-mesh to 10-mesh. This enlarged the capacity of the plant from 138 to 200 tons per day. The production of concentrate increased from 156 tons assaying \$172 per ton to the present monthly output of 600 tons averaging \$75. To obtain this result, the concentrating machinery was augmented by 12 Deister tables and the addition of two tube-mills, each 5 by 22 ft., of Allis-Chalmers make, fitted with the Montana-Tonopah lining, and using Danish pebbles. Owing to the increasing quantity of arseno-pyrite in the ore, further changes are being made. Three more tube-mills are to be added, besides 11 cyanide vats equipped with the Devereux agitator; the intention being to subject all the mill-pulp to cyanidation—not the tailing only, as heretofore. The reason for this change of practice is to be found in the high freight-rate to the smelter. Hence the aim is to make less concentrate, extracting as much of the gold as possible in the mill, thereby limiting the outgoing shipments to bullion. This is to be effected by re-grinding the pyritic constituent of the ore so that the cyanide can dissolve the fine gold intimately associated with it. The pulp will be ground to pass 200-mesh; that is, everything will be slimed. Each tube-mill treats 50 tons in closed circuit, reducing ore passing through a screen with a square opening of ⅞ inch so that 90% of it passes through 300-mesh. At Tacoma the arsenic is extracted from the mispickel as arsenious oxide, or 'white arsenic,' the price of which is 6½ cents per pound at New York.

The most interesting feature of the cyanide plant is the use of the Devereux agitator. Roscoe Wheeler, the mill superintendent, inserted the first of these agitators in February 1916. The agitator consists of a shaft at the lower end of which is a boat's screw-propeller 4 ft. in diameter, having blades 12 inches wide at their widest and having a 'hub' of 9 inches. At 100 r.p.m. the agi-

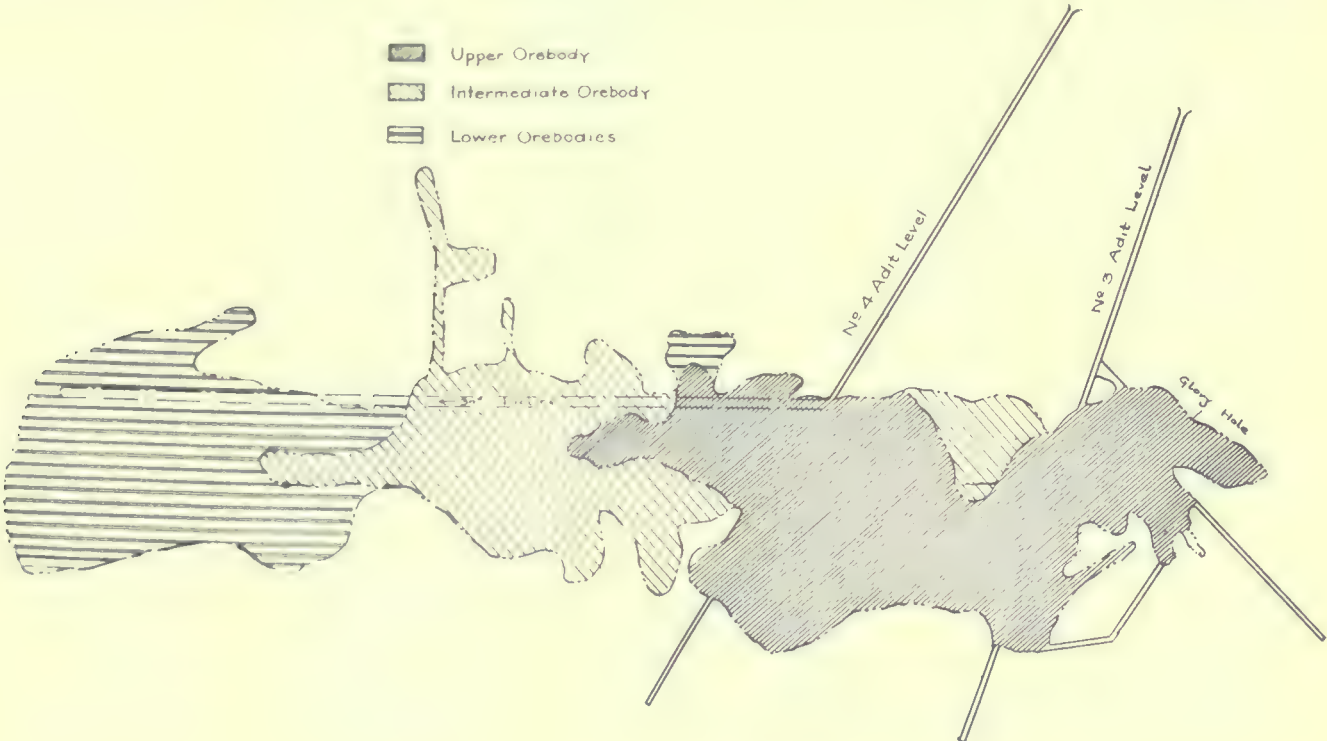

LONGITUDINAL SECTION OF THE NICKEL PLATE ORE CHANNEL.

tator consumes 10 hp. in two operations of 12 hours each, separated by an interval of 24 to 30 hours during which decantation proceeds.

The question of power consumption is crucial. I am well aware. Mr. Wheeler's statement may be accepted without reserve. The measurements of horse-power were made with an ammeter on the motor by the company's electrician. The specific gravity of the pulp in the vats is 1.25 to 1.50, while the specific gravity of the dry ore is 3.3. The vat in which this is done is 30 ft. diameter by a 9-ft. stave above a cone of 22½% slope and 6 ft. high, so that the over-all or net height is 16 ft. The capacity of the vat is 241 tons of water, the charge being

125 to 150 tons of slime, diluted in the ratio of 2:1, or twice as much solid as water.

When in action the propeller floats, there being no weight on the bearings. There was a little trouble at first owing to the lower ring cutting into the shaft, but this was quickly remedied by inserting a collar underneath. Otherwise these propellers have been working since last February without a hitch or delay of any kind and without expense save for grease and power. The agitation is excellent. In watching the movement of the charge it is seen that the pulp runs radially toward the centre uniformly and rapidly, 'boiling up' about two inches on the side of the vat. If the operation is stopped,

PLAN OF THE NICKEL PLATE OREBODIES.

there is no trouble in re-starting, even after the slime has had a chance to settle for several days. This satisfactory effect is due to the fact that the propeller is set six to seven feet above the apex of the cone. During experimental work, Mr. Wheeler found that the best results were obtainable by using two sets of baffleboards of 2 by 12-in. plank extending diametrically across the tank—one set being about 2 ft. above the propeller and the other set placed across the top of the charge. If baffles are not used, the pulp would surge six to eight feet and render operations impossible by causing settling, for the slime is driven to the outer staves by any rotating motion. No air is used, the equipment is exceedingly simple, and the cost is low—\$150 to \$200, exclusive of royalty. The actual cost at Hedley for equipping 11 vats, with motor set and shafting, erected and ready to start, was only \$9000 including royalty. The inventor of the agitator is W. G. Devereux, manager of the Melones Mining Company, at Melones, California.

The mine is operated in the name of the Yale Mining Co. and the mill by the Daly Reduction Co., both of these being controlled by the Hedley Gold Mining Co. The operating cost is distributed as follows:

Mining and development	\$1.82
Transport	0.21
Milling	0.63
Cyanidation	0.52
Shipping and smelting of concentrate.....	1.40
Refining of bullion	0.01
Diamond drilling	0.06
Mine general expense and taxes.....	0.17
Mill and office general expense	0.43
Repairs to mill, power-plant, and tramway...	0.59
Total	\$5.84

Out of the total expenses—\$40,629—in July 1916 the sum of \$14,514 was paid in wages. The shipment and treatment of the concentrate constitutes a heavy item. The salaries of the manager and treasurer are paid from New York. Taxes include the provincial tax of 2% on the gross value of the ore less treatment and transport. The total cost is about \$6 per ton of ore.

In 1915 the production was 74,265 tons yielding \$796,591.78 or \$10.72 per ton. The total production from June 1904 to December 31, 1915, has been 582,760 tons having an assay-value of \$7,181,920, from which \$6,633,752 has been extracted. Dividends to date amount to \$3,451,951, of which \$392,552 was paid in 1915. The capital of the company is \$1,500,000, of which \$1,200,000 has been issued.

In a report made by Mr. Jones on January 5, 1916, the reserve of ore is estimated at 423,552 tons, worth \$4,400,940, or \$10.39 per ton.

The disposal of the concentrate costs \$15.53 per dry ton, thus:

Freight	\$9.75
Smelting	4.68
Loading	1.00
Customs	0.10

The ratio of concentration has increased from 30:1 in 1910 to 12:1 in 1915, so that the proportion of yield in

the form of concentrate has increased from 54 to 71%, and the quantity of concentrate from 1548 to 6188 tons.

The concentrate has a specific gravity of 5.53 and it contains

	%
Arsenic	35.4
Iron	27.8
Sulphur	14.6
Antimony	0.05
Insoluble	17.6
Gold	4.63 oz. per ton
Silver	0.42 oz. per ton

The arsenic is present as an arseno-sulphide of iron, for the mineral mispickel contains 46.1% arsenic, 19.6% sulphur, and 34.3% iron.

Among the mines yielding auriferous mispickel, I may cite the La Belliere, in France, which in 1910 produced 84,784 short tons yielding 38,783 oz. gold and 5211 oz. silver, together worth \$854,737. The output included \$20,000 worth of arsenious acid, obtained from the roasting of the concentrate. The ore, at that time, was being stamped, tube-milled, and concentrated; the concentrate was roasted and cyanided.

A more important analogue is furnished by the Passagem mine of the Ouro Preto company in Brazil. This property has been operated since 1884 under the direction of John Taylor & Sons. In 1910 Arthur J. Bensusan, the manager of the mine, and R. H. Kendall, the metallurgist, each contributed a description of the technical operations.* The geologic conditions are like those at Hedley in so far as the auriferous mispickel occurs in a contact lode marked by such products of metamorphism as garnet, tourmaline, and calcite, besides albite, zircon, and staurolite. The lode is an extreme silicious phase of a granitic apophysis or intrusion between schistose and quartzitic rocks, to which local names, such as itabirite and itacolumite, have been given.

The ore from the mine is discharged upon a grizzly, of 1½ in. spaces, the fine going to the upper of two stamp-mills, each of 40 stamps, while the coarse is trammed to the rock-breaker of the lower mill. Amalgamation is not employed. From the battery the pulp runs over blanket strakes. Of the total extraction of gold, 5% is collected in the mortars at the monthly clean-up and 50% is obtained on the blankets, which are washed in cement tanks at intervals of 20 minutes by boys "under the supervision of a trustworthy man." The concentrate thus obtained is re-washed on more blankets, yielding a tailing that is cyanided and a concentrate that is again washed on blanket strakes before being washed in bateas by women for the recovery of free gold. The reject from the bateas is mixed with the concentrate and re-washed next day. The whole system is antiquated to an extraordinary degree. Copper-plate amalgamation was tried, but it had to be abandoned on account of the excessive 'flouring' of the mercury. From the blankets, outside the battery, the pulp passes over Frue vanners, of which there are 18 in the upper mill and 16 in the lower. On the distributor of each vanner is a blanket, about six

NICKEL PLATE MILL
AND
TRAMWAY.

square feet in area on which three or four tons of rich concentrate is collected each month. The total production of concentrate consists of 350 tons from the vanners and 150 tons of residues from the various washing operations. All of this averages 22 dwt. gold per ton. In the cyanide annex the concentrate is washed with lime, cyanided in a 0.2% solution, and the gold precipitated on zinc in the usual way. The ore averages 7.25 dwt. per ton. From 6000 tons, a month's output, the yield of concentrate is 156 tons, assaying 8 to 9.65 oz. per ton. The amount of free gold retained per blanket is $4\frac{1}{2}$ to $7\frac{1}{2}$ grains only. The tailing from the vanners undergoes separate cyanide treatment in the usual way. On a 7.25 dwt. ore the total extraction is stated to be 92.5%, of which 54% is free gold, saved in the mortars and on the blankets. The cost of crushing and concentrating is 87 cents and of cyanidation 35 cents per ton.

According to the report for 1915 the total extraction, on 85,400 metric tons averaging 7 dwt. 7 gr. per ton, was 91.41%, distributed as follows:

	Quantity tons	Assay gr.	Extraction %	Gold oz.
Concentrate	6,736	43.85	88.71	8,427.75
Sand	63,206	1.423	69.22	2,000.21
Slime	11,630	3.172	81.96	972.42

Thus the total gold extracted by cyanidation was 11,400.38 oz.; and as the total yield was 28,533.75 oz., it appears that free gold to the amount of 17,133.37 oz. was obtained in the mortars and on the blankets. The report states also that 1398 men were employed on a daily average; of these 141 were in the mill and 28 in the cyanide annex. Obviously this method of treatment would not be suitable at Hedley, where the cost of labor would not permit the manipulation incidental to concentration by blankets, nor is the gold in the Nickel Plate coarse enough to render such a method effective.

At the famous St. John del Rey mine, in Brazil, a similar gold ore was stamp-milled, with amalgamation and concentration, the concentrate being re-ground with mercury in barrels, and the loss of mercury was 12 to 13 ounces per ton of ore. At Pestarena, in Italy, an arsenical gold ore was ground and amalgamated in arrastras. There, as elsewhere, cyanidation replaced amalgamation for the extraction of the gold in the concentrate. At Deloro, in Canada, bromo-cyanide was applied by John Rothwell to a heavily arsenical gold-bearing pyrite. Thus the Nickel Plate is following the usual evolution of practice. Whether bromo-cyanide has been tried at Hedley, I do not know. It remains to add that the recovery of the arsenic on the spot is being considered.

The usual process of recovering arsenic consists of roasting at an gentle heat (less than 1200°F.), in order to expel the arsenic in the form of the oxide, As_2O_3 , which is then collected in chambers or flues, yielding a sublimate that has to be purified. It is estimated that from a yearly output of 8000 tons of ore, containing 30% arsenious oxide, a yield of 4,000,000 lb. of arsenic at $3\frac{1}{2}$ c. per pound would give \$140,000. The cost would include roasting \$3 per ton; barreling, 50c. per barrel;

freight, 0.75c. per pound, and selling commission, 1% of the value, making a total cost of \$8.20 per ton of arsenic. The cyanidation of the gold-bearing residue, after roasting for arsenic, would cost \$2 per ton.

At the present time the total extraction at Hedley is 88%, of which 70 to 75% is by concentration, so that it is evident that cyanidation plays a minor part. The position is to be reversed. The idea now is to slime everything, treat with cyanide, return the tailing over vanners and either cyanide the re-ground concentrate or ship it to the smelter, in proportion to the lowering of the freight-rate by the railway company. Tests have been made, using 10 stamps, or a quarter of the mill. These tests have yielded an 86% recovery by direct cyanidation and 9% more in a marketable concentrate. Formerly the concentrate assayed 4 to 6 ounces in gold per ton; now, after cyanidation, the assay has declined to about \$25 per ton. The concentration used to be in the ratio of 10:1 on 600 tons of concentrate monthly; now the shipments will be from 100 to 125 tons only.

The plan of treatment now to be adopted may be sketched thus: crushers, 40 stamps, spitzkasten, the coarse going to eight corrugated-belt vanners, the tailing from which is returned to two tube-mills. The fine from the stamps and the tube-mills is delivered to 12 Deister tables and 16 smooth-belt vanners, the tailing from which is re-classified by four cones, the spigot-discharge being further classified in cones with upward flow of water. The slime from both sets of cones goes to one set of cyanide vats and the sand to another set.

The treatment of the residue for the further extraction of the gold and for the recovery of the arsenic depends upon the freight and smelter rates to be obtained. Like the tariff, metallurgy is a local question.

ALUMINUM DUST. In the November issue of the *Bulletin* of the Canadian Mining Institute, R. B. Watson says: Before the War, aluminum dust cost 33.82c. and caustic soda 2.11c. per pound, laid down at the mine. At the expiration of our contract for aluminum dust in May, 1916, the lowest price at which dust could be bought was 90c. per lb. and caustic soda had risen to 5.77c. per lb. At these prices, the increased cost for these two chemicals would have amounted to about \$33,000 per year. This was excessive and necessitated the finding of a substitute immediately. The utilization of sodium sulphide as a precipitant appeared to present the most promising solution of the difficulty, and the experiments carried out by J. J. Denny, in charge of the Company's research department, were so satisfactory, that in June, 1916, the process was adopted for the precipitation of all the mill solutions. It would appear, that even when prices of all chemicals used return to normal, sodium sulphide precipitation will be cheaper than the method formerly employed.

TIN is now stated to be the principal mineral export of Bolivia, having exceeded silver in 1915. The output of tin in that year was 36,492 tons, valued at \$16,300,000.

Conservation of Resources

By W. L. Saunders

*The question is, shall legislation be urged before Congress to permit co-operative agreements under Federal supervision in certain primary natural resources, such as timber, the ores and deposits of useful metals and the deposits of minerals which are a source of heat, light, and power. The chief reasons why we seek an affirmative answer to this question are, that through co-operation the basic natural resources of the United States will be conserved; that human life, among persons engaged in those industries, will be better cared for, and that the safety, welfare, and prosperity of our people now and in future generations will be increased.

Remember that we are dealing in this matter only with primary natural resources and that we propose to permit co-operation only under Government supervision and regulation. What are the primary natural resources? Concretely they are forests, natural gas and oil deposits, coal, iron ore, and metalliferous ores, but speaking in general terms these things are the sinews of natural security and prosperity in peace and war.

We are an industrial, not an agricultural nation. It is because we have advanced from the farm to the workshop that we have grown great and rich. Our fathers developed these fields through the cultivation of the soil. Through their labors America sustained human life throughout the world, but Nature has provided us with something more than surface fields for cultivation. We have found other resources and through the development of these resources we have become the largest industrial factor in the world. Just as the farm sustains human life so does the mine sustain industrial life. Human capacity to produce through manual labor in the field is limited to a little more than human capacity to live. A big agricultural country does not grow rich and powerful. It does not build up large cities, but it goes on through the even tenor of its way in perpetual desuetude. Not so with a country rich in mines and minerals. Look at Pittsburg, look at Sheffield and Birmingham, and the distinction is apparent.

There are three great industrial nations in the world: The United States, England, and Germany. Belgium, before the War, was great in industry, though limited in size. Russia and China are great in territory and in wealth, but they do not figure industrially as the world is measured, either because of lack of development or through limitations of raw material. The true measure of an industrial nation is its consumption of coal. A nation might produce a large volume of coal and iron ore, but unless it utilizes this production in industry it does not become great in industry. The United States

consumes about 5 tons of coal per capita per annum, England and Germany each consume about 4 tons, while the consumption in France is a little more than $1\frac{1}{2}$ tons, and in Russia about $\frac{1}{2}$ of a ton. We consume about 16 pounds of copper per capita per annum, while in Asia, for instance, this consumption on the entire continent is only a fraction of a pound. Asia is in the position the world was centuries ago, but even Asia may grow industrially, and if so it will be necessary to draw upon the primary resources of the world and mainly of America.

Let us see what is involved in the consumption of coal, oil, and ores through industry.

During the past 25 years the population in the United States has increased about 70%, while the important basic industries have been enlarged at a rate of increase between 500 and 600%. The entire world 100 years ago only produced about 3000 tons of copper per annum. The United States alone today produces over 600,000 tons. The world 100 years ago produced only about 50,000,000 tons of coal per annum. The United States alone now produces over 500,000,000 tons. How long can this last and what will happen when exhaustion takes place? America is the largest producer in most of these things. We export more than half of our copper. The first result of partial exhaustion will be increased price. This, of course, will restrain industry. It will also restrain our ability to defend ourselves in war, for every one knows that the supremacy of a nation in war today depends upon its strength and capacity in oil, coal, iron, and metals. Plenty of soldiers and even plenty of money are not sufficient to resist attack. A nation might be rendered powerless against a smaller country through lack of industrial strength. The real reason why an impasse apparently now exists in the war in Europe is because in industrial strength the Allies and the Central Powers are about equal.

It may be taken for granted, I think, that every one would agree that our primary natural resources should be conserved. The only element of doubt in the matter would be as to how to conserve them. There are many ways of doing this, but as in all big movements the first step leading to results is for people to get together. Concentration and co-operation are our first remedies. As Dr. Van Hise has said: "Through concentration we may have the economic advantages coming from magnitude of operations. Through co-operation we may limit the wastes of the competitive system."

Take coal, for instance; the late Dr. Holmes of the Bureau of Mines has pointed out that the strenuous competition and low price at which coal was produced made it impossible for the operators in certain portions

*An address before the Chamber of Commerce of Pittsburg on January 2.

of the country to mine the maximum amount of coal from the seams that they worked. In their competitive struggle to maintain a place and to keep out of bankruptcy they were obliged to mine only the easy places in the seam, leaving the rest in the ground to be perhaps never utilized. Dr. Holmes is on record as saying that 40% of the coal is wasted in this way. In all probability this wasted coal can never be recovered, even at increased cost, owing to physical conditions.

Federal experts in the Forest service have pointed out that in the lumber industry practically the same conditions exist as in the coal industry. The best timber only is taken, leaving other grades to decay and to afford fuel for forest fires.

In petroleum and natural gas a criminal waste is going on. A paper read at the recent meeting of the American Mining Congress showed that at the present rate of consumption of petroleum all the known reserve resources of the United States will be exhausted in some 30 years. The author of this paper graphically calls attention to this subject as follows:

"I have seen millions of cubic feet of natural gas wasting in the air—gas so rich in gasoline that it dripped from the trees like an April shower. It has been testified before the Corporation Commission of Oklahoma that ordinary methods leave from 25 to 85% of the oil in the ground. The State Mineralogist of California estimates the loss by evaporation of oil as 25%."

In a hearing before the Senate Committee on Public Lands it is shown that the companies which exploited the famous Glen pool of Oklahoma spent over \$11,000,000 in drilling wells when if the whole pool had been exploited by one producer who would have handled the work properly all the oil could have been obtained for a little over \$3,000,000.

Farm products and forests go through a process of perpetual renewal, but the mineral resources of the world cannot be renewed and are absolutely limited. No mine has a lease of life in perpetuity. These valuable things are laid on a thin crust of the earth's surface. Let us, therefore, get together and under Government supervision, and perhaps control, we should secure freedom for fair competition, elimination of unfair practices, conservation of our natural resources, fair wages, and reasonable prices. The anti-trust laws were never designed to act contrary to the public welfare. These laws have been framed to prevent abuse, to conserve the public interest, to prevent private monopoly. The Supreme Court has read into the Sherman Act the rule of reason. Let Congress go further and apply the rule of reason to these primary natural resources by exempting them absolutely and entirely from the provisions of the anti-trust acts, putting these resources aside as great national assets, and through the Federal Trade Commission, or some other Government agency, permitting or even enforcing concentration and co-operation so that the present wild and untamed rush to make money while the sun shines will give place to safety first, looking next at fair profits, fair wages, fair play, and the permanent and increasing prosperity of the whole people.

Gold and Silver Production

The Bureau of the Mint and the U. S. Geological Survey have issued the following joint statement as to the preliminary estimate of the production of gold and silver in the United States during the calendar year 1916. Final figures may show increases especially for silver in some States over the estimates made to the Mint, as the mining industry is generally known to have made large increases in the output of silver-bearing ores in many States.

State or Territory	Gold Fine ounces	Value	Silver Fine ounces
Alabama	339	\$ 7,000
Alaska	785,721	16,242,300	1,426,300
Arizona	211,805	4,378,400	6,711,800
California	1,069,586	22,110,300	1,937,300
Colorado	919,565	19,009,100	7,771,500
Georgia	977	20,200	100
Idaho	47,006	971,700	10,504,100
Michigan	572,600
Missouri	52,000
Montana	221,335	4,575,400	14,751,000
Nevada	407,714	8,428,200	12,784,600
New Hampshire	300
New Mexico	67,870	1,403,000	2,000,000
North Carolina	1,437	29,700	400
Oklahoma	400
Oregon	91,990	1,901,600	163,800
South Carolina	15	300
South Dakota	363,403	7,512,200	212,800
Tennessee	290	6,000	103,400
Texas	24	500	689,500
Utah	173,831	3,593,400	12,965,700
Vermont	24	500	2,000
Virginia	39	800	4,900
Washington	23,791	491,800	206,200
Wyoming	4,054	83,800	4,700
Philippine Islands	74,962	1,549,600	17,900
Porto Rico	29	600	500
Total	4,465,807	92,316,400	72,883,800
Value at average New York commercial price of silver of \$0.658			
			\$47,957,540

These figures compare with the production of 1915: \$101,035,700 in gold, and 74,961,075 fine ounces of silver, valued at \$37,397,300, which is a decrease in the gold production of \$8,719,300, and a decrease in the silver production of 2,077,275 fine ounces, but an increase in silver value of over \$10,560,000.

SMELTING is largely a chemical operation, though often not a simple one. Usually slag that is allowed to cool in a pot exhibits crystalline structure, the development of crystallization being more complete in the centre of the mass and gradually becoming less crystalline toward the side of the vessel until at the rim it may be without visible crystals. The same phenomenon is evident in many dikes, the centre showing porphyritic structure, whereas the portions adjacent to and near the walls are dense and devoid of visible phenocrysts. This is due, as in the slag-pot, to the more rapid cooling of the outer portions, while the centre, retaining the heat longer, has time to crystallize more thoroughly.

Government Aid to Alaskan Mining

By John A. Davis

FUEL. *The question of cheaper fuel stands out above all other conditions affecting the Fairbanks district. In solving this problem the Bureau will do more perhaps than in any other way to help the industry at the present time. The utilization of low-grade ores on any sort of scale is impossible under existing conditions; and even in placer mining, upon which this portion of Alaska has been dependent in the past, a point has been reached where the cream has been skimmed from most of the bonanza placers, with consequent appreciable slowing up of this industry. At present the cost of wood, the only available fuel, is from \$12 to \$16 per cord, and it requires two cords of wood to equal one ton of coal. Thirty dollars per ton for fuel is, of course, prohibitive, except for the richest alluvium. The cost of fuel is a larger item of mining cost here than elsewhere, because the power used in hoisting and pumping is of minor consideration compared with the steam required for thawing frozen ground. I am informed that it is hoped to have the railroad completed from Fairbanks as far as Nenana by January 1, 1918, so that the Nenana lignite can be placed on the market at that time. Such coal, making due allowance for the cost of mining and its preparation for use, should not cost more than \$6.50 to \$7.50 per ton, delivered at Fairbanks. Fuel at this price will make it possible to work a large area of placer ground that cannot be touched at present as well as to open up a number of promising lode properties.

This fuel, however, is a lignite, comparable with the lignites of North Dakota, none too good and containing a high percentage of moisture, making it inadvisable to use it in the raw state. Our first problem would be to study and advise the best methods for preparing it for market. In the States, and especially in North Dakota, this question has received a great deal of study, so that the work of the Bureau can be applied intensively and particularly to the local conditions.

ASSISTANCE TO PROSPECTORS. Another vital point on which the station can be of service is by helping the man with a small mine or prospect and a man or company with capital to get together for their mutual good. In general this can be accomplished by obtaining and keeping as complete a record as possible of the mines and prospects brought to our notice and by making this information available to persons and companies interested in exploratory work. To accomplish this I suggest the use of a system similar to that employed at the Denver station, making a qualitative determination of specimens brought to our notice in return for facts and data as to the occurrence, location, quantity, etc., of the ore from

which the specimen is taken. Such information would be kept on file, and wherever possible checked up by the mining engineer on his field trips, so that ultimately we should have an accurate record of mining possibilities. By tabulating this information it could be rendered available on short notice.

As an example of the value of such work I may mention the fact that the high price for tungsten ore during the past year induced one of the miners near Fairbanks to mine and ship a considerable amount of such ore to Seattle by parcel post. Unfortunately he did not receive news of the attractive market in time for the ore to reach Seattle before the market dropped so greatly as to wipe out any profit he might have made on the transaction. If he could have had the news only a few weeks sooner (and it is this sort of service I would propose to give) he could have shipped his ore in time to take advantage of the high market.

Or, again, the cost of sending an engineer into Alaska from the outside is too great except for well developed and promising prospects, while the work of the Bureau as just outlined would to some extent take the place of a preliminary examination and furnish data that would justify the trip of an engineer, whereas otherwise it would not be worth while, thus promoting the best interests of all concerned.

MINERAL COLLECTIONS. But even more important than this is a complete collection of specimens of the ores known to be or likely to be found in Alaska, and rendering it available for study by anyone interested. Prospecting has been confined largely to the search for gold. In consequence, a majority of the prospectors are unacquainted with the appearance of many other important economic minerals, nor is there any adequate mineral collection available to them for study. By placing such a collection at their disposal, men would be enabled to learn the appearance and value of other minerals than gold, so that they would not overlook them in the field. But more important still, such a collection would tend to get these men intimately acquainted with the work of the station, as well as in the habit of dropping around when in town. To make our office a clearing-house for Alaskan mining facts and news will be a strong factor in securing their co-operation. The importance of all this should not be under-estimated, because I do not see how our work can have its full value to the mining industry of Alaska unless it has just such co-operation from these very men on whom, in the last analysis, depends the good that the Bureau can do. As a part of the plan, it would be necessary to supplement this collection with information covering the market-value of the ores of the various minerals and, as far as possible, the names of men or

*Abstract of a report made for the U. S. Bureau of Mines.

firms interested in their purchase and also their post-office address.

LODE ORES. Provision will also be necessary for experimental work on lode ores, especially gold-quartz. Owing to the present cost of mining, the lode mines in the vicinity of Fairbanks have not received their due share of attention, but with a supply of cheaper fuel this type of mining should come rapidly into prominence and will offer a field for instructive experimental work. During my stay at Fairbanks I had an opportunity to visit some of the quartz properties, and although these are prospects only, nevertheless this district holds some interesting possibilities when economic conditions are improved. To this end we should be equipped to make necessary tests to determine the best method of treating the ores. We need a small experimental laboratory equipped with crushing and grinding machinery and various machines for concentrating ore. This should be on a scale large enough to give the tests a practical value and yet small enough not to involve heavy expense or a large tonnage of ore.

PLACER DEPOSITS. The question of thawing frozen ground also merits attention. The cost of thawing by steam should be studied, as there seems a chance that this can be done more economically than at present. The placer workings are at a critical stage in that most of the bonanza properties have probably been discovered and the future of this industry now depends upon the exploitation of poorer gravel. The Bureau can be of service in suggesting methods for increasing efficiency, saving waste, and lowering cost. The placer deposits require study, not only with the view to saving the fine gold, but also in the conservation and utilization of tin, platinum, and other associated metals. Where stream gradients are low, dredging and other mechanical means of digging the gravel should be studied.

MINERALS OTHER THAN GOLD. There are many known deposits of uncommon minerals in Alaska, such as antimony, tin, tungsten, molybdenum, and asbestos, which are not now being utilized. The building of the railroad will aid such exploitation, and the Bureau should make a systematic study of these deposits so that when the railroad arrives the miners can have the information to encourage them in mining these minerals.

BAUXITE added to refractory clay is said to increase the refractoriness of bricks made of the mixture. Bauxite is added to clay to the extent of 56 and 77% of the mixture. Bricks containing the lower percentage of bauxite are extremely refractory, standing very high temperature. The bricks of higher bauxite content are used as a substitute for magnesite bricks, in open-hearth furnaces.

IRON-ORE shipments on the Great Lakes during the past season amounted to 63,648,298 tons, compared with 46,318,804 tons in 1915. The season covered six full and two part months, August being the record with 9,850,140 tons.

Copper Replaces Aluminum

Aluminum transmission-lines have in several instances been replaced by copper wire during the past two years, the latest being 60 miles of line between the Madison River power-plant of the Montana Power Co. and Butte. The wire was in use for 15 years. The general manager of the power company, F. M. Kerr, states that the following reasons caused it to adopt copper instead of aluminum for long-distance transmission-lines: "(1) Aluminum is softer and weaker and particularly susceptible to abrasions at points of support. (2) Aluminum has a low melting-point and is easily burned in two and destroyed by arcs. (3) Where the wires are supported on suspension insulators, side swinging to the wind must be considered. Aluminum is at a great disadvantage in this respect, and on account of its light weight and large area, will swing up into close proximity to the cross-arms, cutting down the necessary clearance to a dangerous extent. (4) Fire hazard and danger to human life are greater with aluminum on account of its liability to burn in two, drop to the ground and set fire to whatever it touches. The ends of the wire will burn free from the ground and hang down as a menace to life." The statement made that the aluminum lines had been adjudged a failure is not entirely correct, according to Mr. Kerr, who says: "We realize and admit that a successful line can be constructed of aluminum, but as before stated, our experience and observations have placed us on record as favoring copper. While the scrap value of aluminum at this time is high, this fact had little to do with our decision. We were well satisfied that the aluminum lines would have to be abandoned within a year or two in any event, and the only effect the high price had was to hasten this work a little."

THE TERM ASBESTOS, as commonly used, includes half a dozen minerals all having a well-developed fibrous structure, but differing in chemical composition and in some of their physical properties. In its strict application the name is limited to the fibrous varieties of the monoclinic amphiboles. Commercially, however, the most important of the asbestiform minerals is chrysotile, a fibrous variety of serpentine. About 95% of the asbestos used in manufacturing is chrysotile, and it commands a much higher price than any of the other fibrous minerals now on the market. The commercial value of asbestos and the uses to which the different varieties may be put are dependent upon the physical properties; fineness, length and flexibility of fibre, tensile strength, and heat and acid-resisting properties. All of the different varieties of asbestos may be split up into exceedingly fine fibres, and when the finest obtainable fibres, having a diameter of 0.002 mm. or less, are examined under the microscope, they are usually seen to be made up of still smaller fibres. The number and fineness of the smallest fibres distinguishable under the microscope increase with every increase in the power of magnification, and there is no apparent limit to this subdivision.

The Chemistry of Manganese

By M. L. Hartmann

*Oxides of manganese have been known from earliest times. The ancient Egyptians and Romans used pyrolusite (MnO_2) for bleaching glass, although they confounded it with magnetic iron oxide.

A mere enumeration of the chemical compounds of manganese would fill many pages. Because the valence of manganese may be any value from two to seven, and because it acts either as a base or enters into acid radicals, its chemistry is complex. In a great many of the reactions in which manganese enters, its function seems to be that of a carrier of oxygen. This is of course due to its easy valence changes. Thus for example, in the production of oxygen by heating potassium chlorate and manganese dioxide, it is thought that the manganese acts as a carrier or intermediary for the oxygen. Again, the function of manganese in the soil in its effect upon vegetation seems to be to bring oxygen to the plant roots. This is especially noticeable in the legumes, where the nitrifying bacteria unite the oxygen and nitrogen. Manganese is found in all animals and plants, and is probably intimately related to the life processes involving oxidation. Only the compounds of commercial importance will be considered here.

Commercially, manganese compounds are important as oxidizing agents and as coloring materials. For oxidizing purposes, manganese dioxide is the only oxide which can be used. This oxide readily gives up one-half of its oxygen. It may be either natural (pyrolusite) or artificial, but practically it must contain from 13 to 17% available oxygen. By available oxygen is meant the oxygen which is readily given up for oxidizing purposes. Manganates and permanganates are used to a limited extent as oxidizing agents.

Berthollett, about 1785, introduced the use of chlorine into the arts as a bleaching agent, and much pyrolusite was used in the process for making chlorine. The Weldon process was invented in 1867 to accomplish the same purpose somewhat more cheaply. This process is largely used today. The mother liquors from crystallization of ordinary salt frequently contain some bromides. Bromine is liberated from these by treatment with sulphuric acid and manganese dioxide, and is condensed and collected. This is one of the chief sources of bromine.

In certain processes where small quantities of oxygen are occasionally wanted, the method of heating potassium chlorate and manganese dioxide is still used. In this reaction, the manganese dioxide acts as a catalytic agent, being itself not changed during the process. This process has been almost entirely replaced by the electrolytic process and the liquid-air process, which supply

the market with oxygen of all grades in steel cylinders under high pressure.

On account of the readiness with which manganates and permanganates give up their oxygen, these manganese compounds are used as disinfectants and oxidizers. They also find considerable use in medicine. The use of potassium permanganate as an antidote for rattlesnake poisoning is of interest. The wound is cut open, forced to bleed freely, and the crystals of permanganate generously applied to the cut.

Manganese dioxide is used as a dryer in linseed oil in paints and varnishes.

An important use for high-grade manganese dioxide is in the manufacture of dry batteries. In the ordinary dry cell, the current is produced by the dissolving of the zinc and the liberation of hydrogen on the carbon electrode. If a current is taken from a dry battery for any length of time, the hydrogen bubbles cover the carbon pole so effectively that the current is much weakened. In practice, the carbon is surrounded by a mixture of granulated carbon and manganese dioxide, producing water and stopping 'polarization.' It is essential to have the purest manganese dioxide for this purpose, as impurities set up local circuits which shorten the life of the battery.

In dyeing and calico printing, 'manganese brown' (which consists of the hydroxide or oxide) is used.

The use of manganese in the brick industry has become extensive because of the increased demand for fancy-colored bricks in architecture.

In the manufacture of glass, the materials used nearly always contain iron. In the melting-process the iron is reduced to the ferrous condition, and gives a green color to the glass. This is why cheap glass is green. To neutralize this effect, manganese dioxide in small quantities is added to the glass, producing just enough purple color to neutralize the green, thus giving colorless glass. Colorless glass, when it is exposed to bright sunlight for some time, usually takes on a violet color.

Some manganese ores such as wad are used in the crude state in chocolate and brown paints. 'Manganese green' is barium manganate.

Manganese sulphate is sometimes used in fertilizers.

There are other minor uses for manganese compounds. These include their uses in chemical laboratories; in making soap; in dyeing, as a mordant for certain dyes; in staining wood a deep brown.

In minerals and similar materials, manganese is easily detected by a borax-bead test. In the oxidizing flame, the borax bead containing manganese is amethyst, while in the reducing flame it is colorless. Only a little manganese gives this color; too much makes the bead black.

*Abstract from 'Manganese Number' of the *Pahasapa Quarterly*, South Dakota School of Mines, Rapid City, S. D.

Other substances which give colored beads with borax may interfere with the test. The sodium carbonate bead in the oxidizing flame gives a green color when hot and bluish green when cold. Other substances are not likely to interfere.

In the wet way, manganese compounds may be easily detected by boiling the substance with nitric acid and sodium bismuthate (NaBiO_3) or bismuth peroxide (Bi_2O_4), which produces a purple color in the solution (permanganic acid). This test is very delicate, as little as 0.00001 gram in 50 cc. of solution can be detected. Lead peroxide may be substituted for the bismuth compounds, but the test is not so delicate.

Since manganese dioxide is frequently used, and is valuable for its available oxygen rather than for its manganese-content, the available-oxygen determination is frequently made. This is usually accomplished by treating a weighed portion of the ore with hydrochloric acid, driving off the free chlorine that is formed, into a solution of potassium iodide. Free iodine is liberated, and may be titrated with standard reducing solutions.

For the determination of total manganese many volumetric methods have been devised. All of them depend on oxidizing manganese to its highest valence, and then reducing by a standard reducing solution. Certain methods for manganese in steel-works materials have been so well worked out that small 'pills' of the necessary reagents are on the market, with directions reading, "Add one tablet A, allow it to dissolve, and add 1 tablet B," etc., etc. The various methods are described in all books on quantitative analysis, and it would be unnecessary to quote them here.

Metal Price Averages

According to the *Daily Metal Market* the following are averages during the past four years, in cents:

New York—	1913	1914	1915	1916
Straits tin	44.32	35.70	38.66	43.48
Lake copper	15.70	13.61	17.64	28.17
Electrolytic copper	15.52	13.31½	17.47	28.46
Casting copper	15.33	13.18	16.76	26.51
Waterbury copper, average..	15.83	13.91	18.94	28.85½
Pig lead	4.40	3.87	4.67½	6.83
Spelter	5.80	5.30	14.44	13.75
Waterbury brass mill spelter, average	6.06½	5.53½	17.50	17.72
Cookson's antimony	8.52	10.50	*24.47½
Hallett's antimony	8.07½	9.82	*22.31
Chinese and Japanese antimony	7.43	8.53½	29.52	25.33½
Aluminum	23.63	18.59½	33.91	60.73
Silver	59.79½	54.81	49.69	65.66
St. Louis—				
Pig lead	4.26	3.74	4.57	6.80
Spelter	5.61	5.11½	14.16	13.57

*For first four months, no transactions recorded thereafter.

THE Guggenheim and Ryan-Rockefeller groups control three refineries having a present output of 330,000 tons and a prospective output of 360,000 tons of copper per annum.

Volume and Weight of Ore

Quartz in place, in veins, is usually calculated on a basis of 13 cu. ft. to the ton, although it is really somewhat less than this if solid—12.32 cu. ft.—so a small factor of safety is introduced by the employment of the commonly accepted standard of 13 cu. ft. All ore is not solid quartz, however, for it may contain a quantity of sulphide. It is often desirable to estimate the weight of a given volume of ore based upon the exposures in mine workings. In such cases it is necessary to ascertain the relative amount of minerals other than quartz that is present in the ore. Calcium carbonate is a frequent constituent of ores, but as calcite has a specific gravity only slightly less than quartz, its presence would not materially affect the calculation. Take, for example, an ore assaying 20% lead occurring in the form of galena, 25% zinc as sphalerite, and the remainder gangue minerals, principally quartz with some calcite. How many cubic feet of ore of this character, as it stands in the vein will be required to weigh one ton? By the employment of what is called stoichiology, the relative percentage of the various elements entering into the composition of minerals may be figured, using the atomic weights and the valency of the elements, but as *Dana's Mineralogy* gives the percentage of elements forming the most important minerals, a reference to it will simplify the calculation. In that work it will be found that galena (PbS) consists of lead 86.6%; sulphur, 13.4%; sphalerite (ZnS) contains zinc 67%, sulphur 33%. Then, as 400 lb. of lead represents 86.6% of the weight of the galena, the remaining weight—sulphur—is 61.7 lb. Similarly, 500 lb. of zinc constitutes 67% of the blende, there being 246 lb. of sulphur in the blende. We now have in one ton of this ore approximately 462 lb. of galena and 746 lb. of blende, these two minerals aggregating 1208 lb. The balance, 792 lb., is quartz and calcite. A cubic foot of galena (specific gravity 7.5) weighs about 468 lb. Galena present practically 1 cu. ft. A cubic foot of blende (specific gravity 4) weighs 250 lb. Blende present 2.98 cu. ft. One cubic foot of quartz (specific gravity 2.6) weighs approximately 165 lb.; 792 lb. of quartz requires 4.8 cu. ft. of space. These several minerals in the mass then occupy a total of 8.78 cu. ft. for each ton of ore in place.

THE second report of the U. S. Bureau of Mines dealing with accidents at metallurgical works states that at 110 smelters—excluding iron furnaces—and at 560 ore-dressing plants, employing 31,327 and 18,564 men, respectively, there were 38 and 30 killed, and 5718 and 2095 injured in 1915. The number of plants reporting was 92 over the total in 1914, and the accidents were more numerous, as there were 8430 more men at work. The fatalities at smelters was 1.21 per 1000 employed, an increase of 0.02, and non-fatal accidents 182.53 per 1000, a decrease of 20.59. The ore-dressing fatalities increased from 1.59 to 1.62 per 1000, and non-fatalities from 96.71 to 112.85 per 1000.

Conditions in Mexico

By Our Mexican Correspondent

The last Carranza decree effecting compulsory mining work reads as follows:

"The First Chief considers that as yet it has not been possible to collect all the data as to the local conditions of each mineral zone; and these data are indispensable for just now the Department of Fomento in enforcing the decree of September 14, 1916, which provides that the idleness of mines can only be allowed to continue when the excuse given by the concessionaire is proper and well proved in the judgment of the Department. Therefore he has seen fit to decree:

Art. I. The excuses which the concessionaires have given will be assumed as proved; and, in order to comply with Art. II of the said decree, they will be allowed a further time, not beyond three months, in which to start up their mines.

Art. II. Only in the case where the concessionaire proves the existence of a reason which renders quite impossible the exploitation of the mines will the time fixed in Art. I be extended, and then only for the period strictly essential.

Art. III. All mining concessionaires, who, before February 14, 1917, have not started up their properties, or have not been able to justify the excuses they give for continued idleness, will lose their rights and the nullity of their concessions will be declared according to Art. I. The Secretary of Fomento, Pastor Rouaix."

As stated in my letter, published in the issue of October 21, it was impossible for 90% of Mexican mines to comply with the decree of September 14; but in accordance with his usual practice Carranza first made the decree, and did not discover that it was physically impossible to enforce it until some weeks later. Nothing is surer than that Carranza is not half as anxious to get the mines started as are their owners; and if most of them have been idle for several years it is for sound reasons, and never more so than this year when the operation of most equipped metal mines means large profits. The truth is that the political conditions are little better for mining now than they were a year or two ago. While Obregon's defeat of the Villa armies, in the Leon campaign of 1915, enabled Carranza to get control of the Central railroad north of Aguascalientes to the border, Villistas, Zapatistas, and other rebels still range the back country everywhere, except in Yucatan, northern Sonora, and to the north-east of San Luis Potosi. Again, railroad facilities seem just as lacking as last year; whatever rolling-stock has been released from the northern campaign against Villa has been offset by a year's wear and the wreckage of Zapata's derailments. It is a curious commentary on 'simon-pure' Mexican management that at present, with only a fraction of the equipment

and traffic of April 1914 (on which date all American executives were dismissed from the Government railroads) the force of operatives should be 30% more numerous. In order to reduce expenses, now that employees are again to be paid in coin, it is proposed to reduce their number; and the plan to be applied for the elimination of the unfit would delight the heart of the most ardent American spoilsman, for, as officially announced, "it contemplates the retention of only those who have rendered the most service to the Constitutional party." The third reason why many mines will be unable to resume is the impossibility of recruiting a working force, since only a few fortunate centres, like Pachuca, have been

Map of district from Mexico City to Vera Cruz

able to run continuously enough to maintain their force of miners unimpaired. Since 1912, thousands of mine laborers have been killed in battle or died of their wounds, as little or no hospital equipment accompanies the Mexican armies on campaign. Other thousands have died of pest or famine, while hosts have become professional brigands (or soldiers), and are having too enjoyable a life to ever go back to work until compelled to by the police. Finally, there are no more banking facilities for the safe-keeping or transmission of money for pay-rolls and expenses; while the mules, horses, and burros on which thousands of mines depended for transportation have—where obtainable at all—become so scarce as to cost two to three times as much as in 1912, while their forage is also dearer.

Luckily for American miners, Pastor Rouaix, the Minister of Fomento, is one of the most honorable and intelligent of the Carranza leaders, and will probably try to enforce the new decree fairly unless overruled, like Cabrera at Atlantic City, by some "superior political force."

A recent decree changing export taxation is also of interest to miners; it reads: "The first Chief considers that for the return to normality and reconstruction of the country it is proper to facilitate the resumption of suspended national industries and the expansion of ac-

tive enterprises, especially those of mining—so important to the Nation—and has seen fit to decree as follows:

Art. I. From December 10, 1916 till December 31, 1917, the application of the export-tax rates for metals of Art. 10 of the decree of May 1, 1916, will be suspended.

Art. II. During the time of suspension the metals will pay these rates:

- Gold and silver, 7% of the assay-value;
- Copper in bars, 5% of the metal-value;
- Copper minerals, 6% of the metal-value;
- Other minerals, 3% of the metal-value.

Art. IV. If the value of copper gets below 20 cents per pound in New York, the rates of 5% for bars and 6% for minerals of Art. II will be reduced to 5% for both.

Art. V. The exception established by Art. II, part G, of the decree of May 1, 1916, will hold only in the following cases:

In minerals of copper when they have less than 5% copper; in those of lead when under 15%; and in those of zinc which hold less than 20% zinc.

Constitution and Reforms—Queretaro, December 8, 1916.

V. Carranza to Sub-Secy. of Hacienda."

This decree is supplemented by the following circular of the Department of Hacienda of the same date:

"To determine the values of exported metals, this department will fix them each month on the base of New York quotations as follows:

Silver and gold: The value will be the New York quotations exactly.

Zinc: The value will be 75% of the assay-returns and will be calculated on the New York price of zinc with a deduction for smelting, taking as base for the latter the average of the market of Saltillo, Mexico, and Tulsa, Oklahoma. For the other metals, the values will be calculated as placed in the frontier or maritime custom-house, with the idea that when lead is exported as bullion there will be taken into account the freight from the frontier to New York and the cost of refining."

The reductions in the last decree are most weighty for the precious and metal mines, and may mean profits instead of losses for many low-grade properties. They will help to offset the increased costs due to revolution and to the sudden restoration of wages to a metallic basis within the last two months. This restoration, which was started by the decree of October 23 (see my letter published in the issue of December 16), involved much loss to employers and many strikes of workmen; the worst of the latter being a strike of all the railroad hands that shut off every civilian train for 12 days during November. Carranza, when he found his first decrees were unsatisfactory or absurd, resorted to his usual trick of nullifying or changing them till something workable was attained. It may safely be affirmed that no mine-foreman could keep in order a force of even a dozen men if he should deluge them with strange orders every Monday, and then spend the rest of the week retracting or tinkering them. Yet what would ruin a petty foreman is only

diversion for a military autocrat; for, as was observed long ago "any fool can govern if he has the bayonets."

As an example of one of these Carranza tinkering decrees, I will give that issued by César Lopez de Lara, Governor of the Federal district, on November 22, 1916:

"Considering I: That employers, on account of the decrees of October 23 and November 17 affecting the payment of wages, have begun to dismiss a large part of their force without just cause and without moral scruples as to the crisis involved for those discharged, because of the present difficulty of finding new work;

Considering II: That the first duty of all governments is to insure that the living of social classes may be achieved without sacrificing one class for another; it is clear that the Government of the Federal District would fail in its primary duty if it did not rush to the rescue of the labor groups and protect them against the maneuvers of capital, which in spite of its profits, every day more outrageous, strives constantly to increase them even at the cost of its clerks and workmen;

Considering III: That, apart from the injustice which unfair dismissals imply, such conduct, when systematically repeated, can seriously disturb that public order which the authorities must preserve at any cost; I have therefore seen fit to decree:

Art. I. Companies, firms, or individuals engaged in serving the public for gain must not dismiss any of their paid help without just cause.

Art. II. The only just causes for dismissal under this decree will be:

(1.) Fraud or abuse of confidence of employer. (2.) Incompetence or wilful neglect by employee. (3.) Absence from paid work to engage in other occupation. And (4.) Serious lack of respect and consideration for their employers or associates.

Art. III. In case of dismissal without just cause, the owner or manager of the guilty business will indemnify the dismissed person by two months advance salary, payable half in coin and half in infalsifiable notes at the ruling rate for the decennial (ten days) prescribed by the Department of Hacienda.

Art. IV. The complaints alleging an infraction of Art. III must be presented before me, for a resolution after a speedy investigation.

Art. V. The indemnities fixed by me in each case must be paid within 24 hours or the neglectful ones will be punished by either a fine of up to ₱500 gold or 15 days in jail, besides paying the indemnity.

Art. VI. All dismissals since December 17 will be judged by this decree."

It is a pity that the Latin-American News Association of New York (*alias* Mexican-American League) does not enlighten its hosts of American Democratic dupes with English copies of this benevolent decree. The fact that Art. VI was retroactive legislation, forbidden by the Constitution, did not worry this gentle Mexican Caesar, but he got so worried by having to carry out Art. IV that, inside of three days, he lost patience and issued another decree to announce that thereafter Art. V would be enforced without investigation of a complaint's merits.

When Oaxaca declared itself a sovereign State in April 1915, it was too weak in troops to expel Carranza from its ports and the Tehuantepec railway, but it held Oaxaca City and the State's mountain districts until March, 1916, when it was invaded by General Villaseñor, the Carranza commandant at Tehuacan, who soon defeated its general, Higinio Aguilar, at Ocotlan. During the three days of this battle, or rather long-range skirmish, Oaxaca City was without a government, and the public buildings were sacked and their judicial archives burned by a mob—but probably not entirely a ragged one. Then General Higinio's troops entered town on their retreat from Ocotlan, and had just begun a systematic loot of private houses when they were luckily put to flight by a woman screaming "the Carranzistas are coming." Finally, when the invaders actually did arrive, a troop of them took advantage of the isolation of the suburb of San Felipe and robbed its beautiful villas.

The epidemic of hunger typhus that had been raging in Oaxaca all winter reached its culmination in May, and is still existent after destroying thousands. The only mine that has operated since April, 1915, is the rich Natividad, the cyanide mill output of which has been one of the mainstays of the State troops. Nevertheless, a dozen or so of American miners may still be met in Oaxaca City, who seem like ghostly reminders of the happier days of yore, when the State was over-run by prospectors and the social club of its capital had some 150 American members.

The history of Gen. Higinio Aguilar, an active old man, may furnish some food for thought to those who believe with Bryan that "every people is quite competent to create its own government without outside interferences." The wily politician may not be so simple in promulgating this dogma as are some of his foolish followers in accepting it; because it is self-evident that any folk can create 'some kind' of a government, while it is historically proved that few peoples have ever established a 'civilized' state. A Federal Officer for Diaz until middle age, Higinio developed independent ambitions, some 8 years ago, and rebelled against the Government with his whole army in the State of Vera Cruz. Then, joining Madero, he helped him in his revolution; but later shifted against him, when president, to the side of the rebel Orozco. Huerta, on his accession to power, enrolled Higinio along with the other anti-Maderistas, but Higinio liked the bossing of Huerta even less than that of Diaz or Madero, and soon moved again into rebel quarters. After Huerta's fall, Higinio, for awhile, acted with Zapata against Carranza, but afterward he resumed his independence until he was hired by the State of Oaxaca early in 1915. During all these kaleidoscopic changes of allegiance from liberal to conservative and back again, Higinio's troops, varying in number from 2000 to 4000, followed him without a murmur. Whomsoever their trusted chief tells them to fight, he is the enemy! With Higinio they are confident of food and clothes and plenty of diversion, what do they care about political principles? Curiously enough, Higinio is not a common bandit, he rather resembles the German captains

of roving mercenaries who plagued Italy in the 12th century. He does not permit robbery or looting as a rule, because he recognizes its interference with his prescribed discipline, and, like the balance of big Mexican chiefs, he has discovered that retail robbery is much less profitable than political exploitation. To obtain necessary funds after his dislodgment from Oaxaca City, Higinio made a deal with his supposed enemy, General Villaseñor, and between them they extracted from the mule caravans between Puebla and the mountains of Oaxaca "all that the traffic would bear." This canny conduct of General Villaseñor finally became too public a scandal for even the indulgent Carranza to longer overlook; so, after some 18 months at Tehuacan, General

SOUTH-WEST TEXAS AND NORTH-EAST MEXICO.

Villaseñor found himself, one day, ordered to the new satrapy of Matamoros, in Puebla.

In early November, General Pablo Gonzales, who had been in possession of Zapata's capital, Cuernavaca, since spring and still found it dangerous to leave the railroad points, decided to "constitutionalize" the whole State of Morelos. Accordingly he issued a decree inaugurating a new trial of the inhuman Weyler plan for re-concentration of rural populations—a scheme that Huerta had tried to start in 1913. But instead of hunting the Zapatistas, Gonzales suddenly found conditions reversed and had to flee for his life back to Mexico City, though his loss of Cuernavaca was never mentioned by the "free" press of that capital. The wherefore of Zapata's military revival was a new stock of cartridges, and thereby hangs a tale. Estrada Cabrera has long been dictator of the republic of Guatemala, and this deplorable anachronism recently attracted the attention of a group of Carranzista enthusiasts who had long been anxious to imitate the French *sans-culottes* by dethroning a 'foreign' despot. Indeed, all the political and economic theories of the present Mexican revolution have been borrowed from France; and if in practice the Mexican imitators have

rarely gone beyond the blunders and crimes of 1789 so as to repeat the wonderful achievements of that unique epoch, they are blissfully quite unaware of it. Securing Carranza's fatherly aid, the crusaders stocked a ship with 240 soldiers and 5000 rifles with ammunition, and set out on their quest for Guatemala. But Don Estrada is no novice at his job, or he would not have survived for 16 years as tyrant of Guatemala, and he discovered the object of the crusaders before any of them had even landed on his private domain. After this, the disposal of these amateur filibusters was as easy as the drowning of trapped rats, but there still remained a score to settle with his erstwhile 'brother' ruler, Don Venustiano. Accordingly, the latter's enemies have since been given every facility for getting munitions *via* Guatemala, whose frontier is only a few days by mule-trail from Zapata territory. The new rising in the State of Chiapas is likewise part of Don Estrada's reprisal. From time to time also Zapata succeeds in landing munitions at one of the many ungarrisoned lesser ports along both coasts of Mexico. Thus, a short time ago he landed a large cargo at Sta. Cruz de Huatulco in Oaxaca, from a ship flying the Japanese flag.

This year there has arisen a new party, the Legalista, which aims to unite all the anti-Carranza elements, such as the Mexican refugees abroad, the Oaxaca State or Felix Diaz faction, and the Zapata government. The Legalista junta established headquarters "somewhere in the United States," and reserved its strength until the re-election of Wilson nullified its hope of a possible change in American policy. Since early November this junta has been active in helping the southern rebels, but whether they have backed Villa in his recent murderous raids on Chihuahua City and Torreon, I have as yet no information. That corn and beans, the staple foods of the poor, are still fairly plentiful and cheap in southern Mexico, three months after harvest, is largely due to the United States embargo on arms, which, if it continues, will save in 1917 the lives of countless Mexicans who would otherwise be crushed as in 1916 by the wheels of Carranza's juggernaut car, the Casa de la Garda. In fact, at present the Government seems to be using this ingenious food collecting and exporting machine for beneficent purposes, since it has recently opened depots in Mexico City where food is being sold to the masses at low rates.

The embargo has been so strict that Carranza could not even get delivery on munitions long ago paid for, until early in December his New York agent smuggled out a million cartridges on a Ward Line steamer, packed as 'hardware.' Even then the trick was discovered by an alert naval officer on an American ship in Vera Cruz harbor, and the unloading was held-up until the usual "orders from Washington" spoiled all the effect of the Navy's vigilance by letting Carranza have his cartridges. In spite of this favor, the Government journalists have lately been calling President Wilson a hypocrite, and urging, as the indispensable minimum for the new peace treaty, not only the expulsion of General Pershing but the prohibition of embargo, so that in future the nation's

food can be exported and munitions imported without let or hindrance.

One might think from the figures for trade with the United States during the fiscal year ended June 30, 1916, that Mexico had been unusually prosperous. Exports to the United States were ₧97,000,000 (gold) or ₧28,000,000 ahead of 1915, and ₧20,000,000 more than in 1914 (though behind several years previous), while imports were ₧195,000,000, against ₧155,000,000 in 1915, and ₧185,000,000 in 1914, the previous high years. (These figures do not include the precious metals, whose output and export from Mexico have greatly decreased since 1911.) But one would think wrong, because that part of the increase of United States trade in 1916 which does not merely represent a compulsory transfer of trade formerly conducted with Europe, and a somewhat higher value for henequen and petroleum, means an increased import of war munitions and the ruinous export of Mexico's working capital as well as of its essential food. The effect of the export of food is chronicled in thousands of new graves in every State. The effect of the export of capital such as livestock, can be noticed especially in the North, where one may ride hundreds of miles over the endless pastures without seeing even a horse or a cow.

Up to November 1916 the Federal post-office had been conducted according to the old-fashioned morality, and with a trained force, largely a holder from previous régimes. But this reactionary condition evidently had become irksome to the financial reformers of the Department of Hacienda, which decided to alter matters. The first signs of the reform was a decree—in the middle of November—that faced post-office clients one morning, announcing a 150% increase in rates of postage to begin "at once." Hitherto several days' notice had been given of a change of rates. The same decree announced that infalsifiable notes would no longer be accepted for franking foreign mail (which must henceforth be franked with coin), but that the notes would be good for all domestic mail until January 1, 1917. But six weeks is a long time to wait for coin, even if you have promised to do so voluntarily by a published decree, so why wait? Evidently the 'new' morality prescribes no good reason, for on December 6 every Carranza postmaster received a telegram instructing him to repudiate all the stamps already sold for notes, and to sell in future nothing but coin stamps. The holders of note stamps, some of whom had bought a large quantity, relying on the Government's previous promise of their acceptance till January 1, and tried to exchange them for coin stamps at the official quotation between notes and coin (100 to 1) were simply told "nothing doing."

The intervention of the banks of issue (see my letter published on December 16) began in November to yield rightly to the Department of Hacienda, in the form of a specie loan of \$1,000,000 from the National bank. Since that date, the Government has had plenty of specie for all its obligations, but if any of this has been acquired by fresh 'loans,' it has not been mentioned by a prudent press. Having now plenty of coin itself, the Government

is naturally intolerant of any lack of it among civilians, and this condition may justify the somewhat petulant attitude described for Caesar and the Chief Postmaster. On December 15 a second 'Law of Payments' was decreed by the Department of Hacienda, which gives a fairly reasonable table for adjusting unpaid and future real-estate rentals in coin, and establishes a moratorium for all other debts, including those pending in the Courts. This moratorium is to last "only the brief period before the resumption of the Constitutional régime," after which happy event, the new public powers will again tackle the problem caused by the "re-appearance of coin in the markets and the difficulty of its circulation simultaneously with paper money." This last decree appears to close the open season for Mexican creditors, which has been on since 1913, and in which this pestiferous class of game has been hunted to its lairs and largely exterminated. The worst sufferers from this hunt may prove to be bank depositors, for many of the banks were perhaps insolvent even before the Government decided last September to relieve them of further worry as to the custody of their cash reserves. Under the Mexican plan of discount, the time-limit of notes is nominally six months, but the custom has been to renew these notes regularly from year to year. In normal times this system was harmless, but the recent insanity of Government finance has altered matters and forced the banks to accept depreciated paper in payment for millions of their original specie loans. As a part offset to this ruinous depletion of assets, the bankers have been able to buy-up for paper money many of their own bank-bills, legally redeemable in coin. Also, as they have accepted no new ordinary deposits since March 1915, they have made good gains by paying off in paper money all checks and drafts made against their 'old' deposits, mostly made in specie. Finally, some of the more unscrupulous bankers have forced any depositors who were simple enough to be illegally intimidated to withdraw their entire deposits in paper money, the value of which meant only a fraction of the original coin deposited.

For the first 10 days of December, the infalsifiable paper peso was officially quoted as worth 1 centavo in Mexican gold; for the last two periods of 10 days the quotation was $\frac{2}{3}$ centavo or $\frac{1}{30}$ of the peso's nominal value of 20 centavos when first issued last May, which value was not officially recognized as depreciated as late as the first 'Law of Payments' of September 15. With its recent refusal to accept its infalsifiable paper money in payment for either revenue or postage-stamps, the Government has now practically completed its repudiation; though the paper money is still receivable for certain local taxes at its official quotation. Yet as late as November, the reputable merchants of various cities were accused of abetting the 'reactionaries' in depreciating the paper money; and many were fined, jailed, or even made to perform as public street-sweepers because of refusal to accept it in payment for their goods at the official quotation, always below the market one. Thus in less than eight months Louis Cabrera has issued ₧500,000,000 of infalsifiable notes and not only repudiated them all,

but ₧800,000,000 of older Vera Cruz notes besides. This makes a total repudiation of ₧1,300,000,000, a feat of high-binder finance which is probably the world's record for speed since history began. And yet few Mexicans appreciate the enormity of the public swindle or have even any grasp of what has actually happened. At least Cabrera has lost little of his popularity in Government circles; he appears to have a life place as Minister of Hacienda, and few Mexicans have been more fêted by prominent American Democrats.

During the past six years of revolution, Mexico City has never been as unsafe in the streets at night as recently. Many of the footpads when apprehended have proved to belong to the Federal army or secret service, while there are many that ply their trade with the aid of automobiles. It is not unusual for several dozen victims to be brought to the hospitals as the result of a single night's hold-ups. Though many businesses are paralyzed or shut-down entirely, the Capital's trade in luxuries has never been more active, for the Carranzista

A FIELD OF MAGUEY, MEXICO.

chiefs are liberal spenders; golden spurs for the men and clusters of diamonds for the women have become almost *de règle* among the official elite. Nevertheless all successful "liberators" do not care to waste their substance in riotous living, but instead are providing for future rainy days. Some prefer Spain as a future home and are imitating Luis Cabrera, who purchased last spring a million-peso estate near Madrid. Others favor the United States, like Don Venustiano, who is said to have sent out ₧4,000,000 in Mexican coin in the same private car that took his family to Texas in October. A third group, like General Castro, governor of Puebla, less timid than the preceding, expect to continue indefinitely in Mexico and are preparing to found a new landed aristocracy to replace the one now in exile. This group thinks less of the abolition of peonage than it does of the cheapness of the land, which it is rapidly acquiring; some from the intervention commissions, who confiscate the estates of 'reactionaries,' some from the discouraged owners who can't afford to pay the excessive military demands for protection against bandits, and the others because the Carranza prohibition of further real-estate purchases by foreigners has greatly restricted the number of land-buyers and depressed the prices at forced sales.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

RENO, NEVADA

RECENT PROGRESS AT VARIOUS MINING CENTRES.

The new year finds the Ely district in a favorable condition, indications pointing to a largely increased output during 1917, provided copper prices remain satisfactory. Nevada Consolidated is producing upward of 12,000 tons of ore daily, with most of this derived from steam-shovel pits. Four to five cars of silicious carbonate ore are shipped daily to the Garfield, Utah, smelter. Much new work is going on at the mines and plant, preliminary to a heavier yield. The Coppermines Consolidated is doing extensive work from the Morris shaft, and the first 500-ton unit of the re-modeled plant is nearly ready for service. Another 500-ton unit is to be erected shortly. The Callow flotation system is employed.—Control of the Ely Consolidated group has passed into the hands of W. O. Kay, C. W. Geddes, F. H. Vahrenkamp, and the Gobe-Pingree-Eccles interests. Arrangements have been made for extensive work under the management of C. W. Geddes. The Ely Consolidated comprises 400 acres pierced by the Zack, Brilliant, and American shafts. The Zack is 700 ft. deep, and is the main working outlet. The Brilliant has a depth of 625 ft., and the American is down 350 ft. On the 400 and 600-ft. levels of the Brilliant shaft, and the 500 and 600-ft. Zack workings, large bodies of low-grade ore are exposed. Early shipments of the higher-grade ore are anticipated. Tests may be made at the Copperopolis, California, flotation plant of the Calaveras Copper Co. The manager, S. M. Levy, of the latter company is president of the Ely Consolidated.

Copper mining is claiming considerable attention in the Jungo field of Humboldt county. The Craven Copper Co. has developed ore to a depth of 230 ft., the copper occurring in the form of cuprite and copper glance. Machine-drills have been installed and small shipments are being made, the ore averaging \$100 per ton. P. H. Craven is manager.—On the Copley property ore of shipping grade is being broken across faces from 2 to 4 ft. wide. Copper predominates, but there is some gold and silver.

Further delay has been experienced by the Goldfield Consolidated company in the placing of its flotation plant in commission, due to severe storms and interruption of electric-power service. All equipment is in position. It is probable that ore from other mines will be treated, particularly the Atlanta and Kewanas. Meanwhile the cyanide plant is treating 1000 tons of low-grade ore per day, yielding monthly net profit of \$15,000.—The Jumbo Extension company has assembled a Calyx core-drill on the 1017-ft. station of the Jumbo Extension shaft, preparatory to prospecting the shale-alaskite contact. The quartz fissures extending into the alaskite will be given particular attention. Unless new ore is found, the productive life of the Jumbo Extension mine is nearly ended. The company has taken the Copper Mountain property, in the Rand district, 45 miles east of Luning, under option.

Goodsprings district continues to report substantial progress. Net earnings by mines of the district in 1916 are estimated at fully \$4,000,000, of which over \$3,000,000 was derived from lead and zinc ores. The remainder came from copper, silver, gold, platinum, and palladium.

Pioche is shipping a large tonnage of zinc, lead, and silver ore and concentrate. The mill of the Consolidated Nevada-Utah Mining Co. is crushing approximately 600 tons of ore daily, and yielding 20 tons of zinc concentrate, and 1 ton of

lead concentrate. The Callow system of flotation is employed. The company is preparing to increase the capacity of the mill, and to conduct mine operations along broader lines.—The Hamburg Mines and Uvada companies are contemplating more extensive work, and the Highland Queen has passed into the hands of strong interests.—At Atlanta the Atlanta Home Mining Co. is developing large bodies of low-grade gold-bearing ore, and it is probable that a large mill may be erected next summer. Heavy shipments continue to be made by the Prince Consolidated and Amalgamated Pioche.

The Nevada Douglas Copper Co. is increasing mine operations at its holdings near Ludwig, and it is likely that considerable ore will be shipped to the Thompson smelter as soon as that plant goes into commission. The management contemplates the erection of a 100-ton flotation plant, operating in conjunction with the leaching plant now in service. Approximately 300 men are on the pay-roll.—The Mason Valley Mines Co. has practically completed arrangements for the blowing-in of the first unit of its Thompson smelter. Work has been resumed in the mines. A large number of small copper, gold, and silver-lead mines tributary to Yerington have recently resumed work, in anticipation of shipments to the Thompson plant.

The Willow Creek Gold Mining Co. is planning construction of a mill in the spring. The property is at Willow Creek, between Ely and Tonopah, and has produced some rich ore. A large quantity of milling ore is on the dumps, and a fair quantity blocked-out underground. F. H. Scott is at the mine arranging for further operations.

Two mills, the Elko Prince and Coots, are operating at Gold Circle, and the Esmeralda plant will go into commission shortly. The bullion output is stated to approximate \$70,000 monthly, of which the Elko Prince is producing over \$35,000.

AUSTIN, TEXAS

THE SULPHUR DEPOSITS OF WESTERN TEXAS BEING EXPLOITED BY DEVELOPMENT COMPANIES.

The fact that several companies of large capital recently acquired holdings in the sulphur district of Culberson county of western Texas, and that development and mining of the mineral deposit is in progress, caused the Bureau of Economic Geology and Technology of the University of Texas, at Austin, to send recently Dr. Emil Bose and Edwin Porch to make an investigation of these sulphur beds. Their preliminary report says:

"Sulphur deposits in West Texas have been known for a long time, the most important are located in Culberson county, near the Rustler hills, from four miles east to twelve miles west of them, and north-west of Toyah from 35 to 65 miles. There are six companies doing prospecting or development work in the district, and with two exceptions, all the work is being done east of Rustler hills and within one to five miles of Maverick Springs. The sulphur occurs as bands, incrustations, and impregnations or disseminated crystals in a brown, porous gypsum; and in a brown, porous firm earthy material; as bands, frequently associated with much crystallized secondary gypsum; in a hard black, gypsiferous, or silicious rock, the bands extending both vertically and laterally; as impregnations or replacements around and in the altered pebbles of what was once probably limestone conglomerate. In one place

the sulphur deposit has some connection with what appears to be a large cave, filled with spring deposits. In many places the sulphur deposits come to the surface, or close to it, but prospecting is difficult, owing to the fact that in most cases, there is nothing on the surface to indicate the presence of the sulphur below. There is no doubt that the Culberson County deposits are widespread and contain considerable sulphur, but they are irregular, varying greatly not only in the vertical and lateral extension of the sulphur-bearing rock, but also in the sulphur content. The deepest shaft noted was 35 ft. This shows some sulphur from top to bottom, so there is a chance of finding more sulphur as greater depth is reached. The district may be considered as still in the prospect stage, and not enough sulphur-bearing rock has been developed to assure the success of the district. Under normal conditions, sulphur is a low-priced commodity, and such large tonnages have to be handled that heavy expenditures for equipment are never justified until the deposits have been thoroughly explored. Other factors to be taken into account are the most efficient method of extracting the sulphur from the rock and the cost of transportation and marketing."

PLATTEVILLE, WISCONSIN

HEAVILY INCREASED OUTPUT FOR DECEMBER.—NEW OPERATIONS.

Operations, in the Wisconsin zinc-lead field, for the concluding month of the year 1916, in spite of serious drawbacks due to inclement weather and bad wagon roads resulted more satisfactorily in a general way than for any one month of the year. It has been observed over a number of successful years that the best showings were made about mid-summer but this year the month of December is entitled to distinction as the banner month. Production in the face of a rapidly declining market, following breaks in the price of spelter, was the highest of any one month of the year, the gross recovery of mine-run product aggregating nearly 50,000,000 lb.; shipments from mines to separating plants, in the field and to smelters direct from mines were the highest recorded by the field in a single month, running 55,510,000 lb.; newly developed mines, with complete modern mining-rigs came into active service at several points; extensive improvements involving the expenditure of \$500,000 were brought to a successful issue in connection with the leading electric-power plants supplying the mines with current; the labor demand showed no signs of abatement, skilled labor especially being sought persistently, mill-men, machine-men, foremen, engineers and experienced miners having first call in the recruiting of working forces for new zinc ore producers; exploration work, with drill-rigs, was continued throughout the month, at times under distressful conditions, with numerous rich strikes reported; a scarcity of cars available for prompt loading developed at times which carriers relieved as well and as quickly as possible. At one time eastern roads laid an embargo on zinc ore destined to eastern smelters but prompt and efficient work by leading mine officials brought relief. There was one phase of the industry that marred its peaceful and progressive trend and that was a number of mine fatalities taking an unusually heavy toll in human life. With the exception of one instance, where two were instantly killed, the causes were unavoidable as far as management is concerned. Generous restitution was made to the families of the unfortunate men.

Exceptionally high prices for zinc ore at the beginning of the month was the stimulus to operations at a maximum. Had the opening figures the first ten days of the month been sustained there is no telling what the figures on production and shipments would have reached as premium grades of refinery plants held at \$105 per ton, down to \$98 per ton base on seconds, and medium grades, down to 50% zinc assays held at \$95 per ton. Profits were enormous. The first sharp break following the drop in the metal market came about the middle of the month and the figures receded to \$93 for high, and

\$89 on seconds, and mediums at \$83. One week later came another break, worse than the former, the top price receding to \$75 per ton base on premium and 60% ore, with the range on seconds and medium going to \$70 and \$65, respectively. These sudden reversals took the heart out of the independent concerns that were left with an indifferent demand for medium and low-grade ores, which previously had been much sought by representatives of reduction plants operating in the field.

The large operating groups maintained a steady output and the advantage of nearness to the railway enabled them to keep up a steady production, the shipments keeping pace with output. Many independent operators, somewhat removed from the track were at times entirely isolated on account of bad roads, the freezing weather of the first part of the month giving way to rain and sleet, which did much damage to power and milling plants besides making roads impassable. The reserve in the field, while not great, represented the last week's production. This was held and consisted of both the high-grade refinery ore and low-grade concentrate.

The market on lead ore was better sustained throughout the month than that on zinc ore. Prices mounted gradually during November until offerings nearly reached the figures attained by zinc ore. The closing days of the month witnessed

THE WISCONSIN ZINC REGION.

a break in prices as pronounced as it was sudden, the price receding from \$95 per ton high, to about \$80. Such ore as had been marketed came in the first three weeks of the month under the higher priced bids and when the market declined no ore was offered. The reserve in the field at the close of the month was estimated at about 1000 tons. Pyrite enjoyed a season of exceptional prosperity, the price becoming standard at \$7 per ton. Shipments of fines from separating plants did not run as high as had been anticipated. Many mines long abandoned, but capable of producing this class of ore in quantity were re-rigged and put into operation and some crude ore began to find its way to the track before the close of the month. A new outlet for carbonate zinc ore enabled a few miners in the northern districts to make shipments but the quantity of ore marketed was not large.

In the Highland and Mifflin camps two new mills were waiting on developments made to secure an ample water supply for milling. In the Linden district two new mills were put in operation, one for the Spring-Hill Mining Co., capacity 150 tons each 10-hour shift, and the Weigle property for the Polard-Saxe Co. In the Mineral Point district, the Harris Mining Co.'s old leasehold and equipment was being fitted up for active work. At Platteville the New Rose Mining Co. completed a small plant and was milling before the close of the year. Benton camp has two new producers with equipment,

one for the Wisconsin Zinc Co., on the Longhorn mine, and one for the Frontier Mining Co., on the Bull Moose range. A wet-mill was also being constructed for the Wisconsin Zinc Co. to be operated in connection with the Skinner zinc ore refinery, to eliminate contaminations from refined ores. A large warehouse was also under construction to store supplies for the mines, mills, refineries and boarding-houses operated and maintained by the Wisconsin Zinc Co.

Shipments, by districts, for the month of December were made as here shown:

District	Zinc, lb.	Lead, lb.	Pyrite, lb.
Benton	22,778,000	272,000
Mifflin	6,778,000	74,000
Galena	5,626,000	80,000
Hazel Green	4,284,000
Shullsburg	4,230,000	308,000
Linden	4,012,000	196,000	1,244,000
Cuba City	3,670,000	2,572,000
Platteville	2,060,000	60,000
Highland	1,034,000	60,000
Montfort	424,000	64,000
Potosi	408,000	50,000
Dodgeville	190,000
Mineral Point	16,000	3,036,000
Total	55,510,000	1,164,000	6,852,000

The Mineral Point Zinc Co., running on full time, three shifts daily, with two reduction plants, handled 204 cars of crude ore during the month, 15,320,000 lb., from which was recovered and shipped to smelter at DePue, Ill., also, 94 cars of top-grade blende, 6,928,000 lb. Out of a total of nearly 50,000,000 lb. of mine-run ore, there was recovered and shipped to smelters 28,898,000 lb. of both refinery and high-grade ore. Fifteen buying outlets were afforded zinc-ore producers during the month. Lowering markets near the close eliminated companies that had been active when prices were high and the demand strong and steady. Producers were optimistic regarding the outcome, many claiming that prices would advance after the holiday season as production would decrease with continued winter weather. A reduced output, it was shown, was being made in the Missouri field and that such curtailment would necessarily mean a scarcity of ready ore for smelters. German peace proposals it was held was the determining factor in the market situation and the fact that no definite conclusion had been reached, it was argued, would exercise an influence toward the upholding of high prices, there being small stocks of metal in the hands of large spelter manufacturers.

An order was issued early in the month by the State Railway Commission to the Chicago & Northwestern Ry. Co. to construct and maintain a branch from Strawbridge, on the Galena division, to the Skinner refinery, a portion of the expense to be furnished by the leading mining companies to be benefited. The new branch will afford relief to nearly all the zinc mines in the New Diggings district, all of which are at present compelled to team their ore to track. Mines isolated from hard-bottomed roads are frequently shut-off for weeks at a time at this season of the year. A sensational output of ore from the new Mulcahy mine, in the Shullsburg district, refined on the ground by an independent separating-plant, confirmed the claims frequently made by the lessees, the Oliver Mining Co., that it had in the making one of the best zinc ore mines in the field. The Rodhams Mining Co. introduced a new power and milling-plant during the month and began an increased output of both lead and zinc ore. In the Potosi camp, the Chicago Zinc Co. has a new 250-ton mill on property recently developed, but shipments will not begin until well along in January. Improvements in the plant of the Wilson Mining Co. enabled this concern to maintain regular shipments which will increase as the deposit is more fully developed.

VICTORIA, BRITISH COLUMBIA

REVIEW OF METAL PRODUCTION DURING 1916.

A preliminary estimate of the total value of the mineral production of British Columbia in 1916 places the amount at about \$45,000,000, compared with \$29,447,508 in 1915, and \$32,440,800 in 1912, the latter having previously been the year of highest annual value on record. While high prices for some of the metals are partly responsible for the marked advance, there were also substantial increases in quantities of lead, copper, and zinc.

Returns for gold, silver, and lead are incomplete, but those available indicate that there will be a decrease in the amount of gold produced. Water for washing gravel was short in the larger placer-districts, Atlin and Cariboo. The coke supply for smelting having been inadequate, the output of ore was somewhat curtailed at the bigger mines at Rossland and in the Boundary district, with a consequent smaller production of lode gold. The Hedley Gold Mining Co.'s output, while confirming previously announced average value of ore in reserve, was lower in quantity than in 1915. Another contributory to the decrease was a suspension of production at the Queen mine. Nelson division, while re-timbering the main shaft, timbers in which had collapsed.

There seems to have been more silver produced than in any other year since 1902, but lacking returns from several of the more productive mines of Slocan district, whence usually comes fully one-half of the silver produced, no definite statement can yet be made. An increase from East Kootenay, Ainsworth, and Coast district mines is expected, but a decrease in parts of West Kootenay appears likely.

Lead is thought to have made a substantial gain, probably between 40 and 50% in total quantity, chiefly from the Consolidated company's Sullivan mine. The Bluebell, Comfort, and Highland mines, in Ainsworth division, and the Galena Farm, Lucky Thought, and Ruth in Slocan division, shared considerably in the increase. The general utilization of lead-zinc ores now practicable makes for an appreciably large increase in the recoverable quantity of lead. Practically all the metallic lead included in the estimate of production was recovered at the Consolidated Co.'s smelting and electrolytic refining works at Trail, where additions to plant, etc., in the lead department, included a new lead mill, bedding system for roasters, another Wedge 7-hearth mechanical roaster, steel building over the Godfrey roasters, charge bins and weighing hoppers for the three large lead blast-furnaces, generator-room and more generators for the Cottrell dust and fume precipitation plant, and briquetting plant for flue-dust and lead fume.

Copper mining has become the most important branch of the mining industry of British Columbia. Provincial official statistics show a production in 1912 of 51,456,000 lb. of copper, and in 1915 of 56,918,000 lb. Returns for 1916 are not yet complete, but an estimate of 70,000,000 lb. is within the mark. Two districts, namely, those known respectively as Boundary and the Coast, are the present chief sources of copper ore. For 1915, the Provincial Mineralogist showed that of the above mentioned total, the Coast district, including the Granby company's mines near Observatory inlet and mines in the Hazelton region, produced 60.65%; Boundary district 30.57%; and Rossland mines 8.17%, leaving only 0.61% for other parts of the Province. For 1916 the proportions are estimated to have been approximately: Coast district, 69%; Boundary district, 23%; Rossland, 6%, and other parts 2%. In a report published recently, Alfred W. G. Wilson, chief of the Metal Mines Division, Canada Department of Mines, states that a rough estimate indicates that the known ore deposits of British Columbia contain in excess of 500,000 tons of recoverable copper, equal to 20 years' supply at the present rate of production, and suggests that other equally important discoveries will be made in the Province in the future. Incidentally, it is

noteworthy that a rough estimate of known copper ore reserves at the Granby company's mines in the Coast district is 18,000,000 to 20,000,000 tons; of those of the Britannia company, in the same district, 17,000,000 tons; and of mines in Boundary and Similkameen districts, 16,000,000 tons.

The question of refining copper in Canada had serious consideration in 1916. In his report, above alluded to, Mr. Wilson includes in his general conclusions the following: (1) British Columbia is the only province which produces enough copper annually to support an electrolytic refinery. (2) Within a short time the total amount of copper produced from districts tributary to the Pacific coast of British Columbia will probably be more than one-half the total production of Canada, and will be much in excess of that tributary to interior points. (3) For various reasons (cited in detail in the report) the coast of British Columbia offers the best choice of sites for a refinery.

Concerning copper smelting facilities: At Trail the Consolidated company has five copper blast-furnaces, with a smelting capacity of between 3000 and 4000 tons daily. Recent installations there include two copper converters and turbo blowing-engine for same; reverberatory-furnace and anode-casting plant. An electrolytic copper refinery, capacity 20 tons a day, has been built and equipped, and a copper refining furnace and casting equipment provided. In the Boundary district there are two copper smelters—those of the Granby and British Columbia copper companies. The Granby company has eight blast-furnaces, capacity 4000 tons per day, and three converter stands with 10 shells. Producing capacity is 50 tons of copper daily. The British Columbia Copper Co. has three blast-furnaces with a total capacity of 2000 tons, and two converter stands with seven shells. In the Coast district, the Granby company has at Anyox a blast-furnace capacity of 3000 tons, and three basic converters of the Great Falls type. Both Granby and B. C. companies ship their converter copper to eastern United States refineries. The latter company is developing a new copper field, near Princeton, Similkameen, with about 12,000,000 tons of ore estimated as available. It is intended to concentrate the ore by tables, jigs, and flotation, and smelt the concentrate. The Tyee Copper Co.'s works on Vancouver Island have been inoperative for several years; last month their sale to New York men was reported, and it was stated \$100,000 will be spent in modernizing the plant there. The Britannia company, near Vancouver, concentrates its copper ore and ships its concentrate to smelting works at Tacoma, State of Washington.

Production of zinc in British Columbia has been gradually increased in recent years, until now it is an important branch of the mining industry. In 1911 the quantity produced was 2,634,000 lb., in 1913, 6,759,000 lb., and in 1915, 12,982,000 lb. Production figures for 1916 are not yet available, but there is little doubt that it will be found the year's output was more than twice as much as that of 1915. The chief producer was the Consolidated Mining & Smelting Co., from its Sullivan mine, in East Kootenay, which shipped nearly 100,000 tons of lead and zinc ores to Trail during the year. At the end of 1915 the directors of the company announced that important additions to the works at Trail had been authorized to allow of the production of zinc on a commercial scale, and that a contract had recently been entered into with the Shell Committee for the supply by the company of a considerable quantity of zinc. The plant designed and then being erected was for a production of 25 to 35 tons of spelter per day, but later provision for more than twice that quantity was undertaken. The enlarged plant will allow of treatment of 600 tons of zinc ore daily, and production of 75 tons of electrolytic refined zinc. The equipment includes 13 Wedge mechanical 7-hearth roasters, Cottrell dust-precipitating plant, leaching-plant, electrolytic-tanks, melting-room, generator-room, laboratory, etc. The commercial production of electrolytic refined zinc or spelter was commenced during the year, and shipment of that product has been in progress for months.

Zinc concentrate in considerable quantity is made at half a dozen or more concentrating mills in the Slocan district, and the magnetic separation of iron from the zinc in concentrates is being successfully carried out at works at Kaslo, Kootenay lake. Besides the customary table and jig water concentration, flotation has been provided for in mills at Silverton, and Sandon, Slocan. A small part of the zinc concentrate produced in Slocan is shipped to Trail, but by far the larger part of it goes to reduction works in the United States. The utilization of the zinc in the ores adds considerably to the earnings of most of the larger companies operating in Ainsworth and Slocan divisions, as well as to the Consolidated company, with lead-zinc mines in East Kootenay.

The Standard Silver-Lead mine is to be prospected by diamond-drilling. The ore in this mine occurs as short lenses.

Vancouver Island coal mines made a gross production of approximately 1,510,000 long tons of coal, as compared with 1,020,000 tons in 1915. After deduction of coal made into coke, the increase was about 416,000 tons. The manufacture of coke, resumed by the Canadian Collieries (Dunsmuir) Limited, in 1915, to supply the Granby company for its smelter at Anyox, was enlarged in 1916, the output having been about 28,000 long tons, against 5450 in 1915. Coal mining was quiet throughout the spring and summer in Nicola district, but orders for coal could not all be filled, more miners being unobtainable, as winter came on. There was a decided increase in demand for coal from the Princeton colliery, Similkameen, especially from Vancouver, and difficulty was experienced in filling extra orders. Conditions in the Crowsnest district were unfavorable in several respects. Disasters at two of the Crow's Nest Pass Coal Co.'s mines, at Michel and Coal Creek, respectively; difficulty in obtaining sufficient miners and other workers, and suspension of work for short periods while demands for higher wages were being dealt with, all combined to restrict output of coal and lessen profits. Notwithstanding these drawbacks, however, the quantities of coal mined and coke produced were larger in 1916 than in 1915. The output of coal was about 812,000 long tons gross; deducting 353,000 tons made into 242,400 tons of coke, the net output of coal was approximately 459,000 tons. These figures compare with the 1915 production of 790,028 tons gross and 446,537 tons net of coal, and 240,421 tons of coke. The Corbin Coal & Coke Co. was the only other coal-mine operator in the Crowsnest district in 1916; its output was about 69,000 long tons against 62,544 tons in 1915.

Total production of coal in the Province in 1916 was nearly 2,496,000 long tons gross, and 2,070,000 tons net; of coke it was 270,475 tons. The corresponding figures for 1915 were coal, 1,972,580 tons gross and 1,611,129 tons net; coke, 245,871 tons.

Demands for higher wages made by workers in the metal mines and reduction works were adjusted amicably, generally, without suspension of operations. As in the coal mines, workers were short in some of the larger metal mines. The development of promising though not yet largely productive properties was continued, notably in Similkameen, Nicola, Lillooet, Vancouver Island, Alice Arm of Observatory Inlet, various parts of the Skeena and Babine regions, and Princess Royal island. Mine safety matters had more attention, safety committees having been organized at some of the larger mines and works, and appliances for the protection of the workers obtained. Much more attention was given to the mining possibilities of various fields in the Province by United States mining men, in several instances followed by activity.

The total amount paid in dividends by mining companies (more than \$3,000,000) was larger, having about equaled the totals of the years of 1914 and 1915 combined. The dividend-paying companies were the Consolidated Mining & Smelting, Crow's Nest Pass Coal, Granby Consolidated, Hedley Gold, Rambler-Cariboo (Slocan), Sheep Creek Motherlode, and Standard Silver-Lead companies, several of which also made comparatively large additions to their profit and loss accounts or provision for discharge of debenture obligations.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

It has been officially stated by the United States Land Office that no leases of coal lands in the Matanuska and Bering River fields of Alaska have yet been made under the Act of October 20, 1914. The regulations under the Act were issued May 8, 1916, and eight applications have been filed for lands in the above coal-fields. Consideration is being given to these applications and it is expected that the awards will be made within a short time. The Land Commissioner states it is hardly probable that any mining will be done under the leases before the opening of spring.

JUNEAU. During December the Alaska Gold Mines produced 196,495 tons of \$1.22 ore. The past year's returns were as follows:

	Tons	Value	Recovery, %	Residue, cents
December	196,495	\$1.22	81.54	22.0
November	167,600	1.13	81.71	20.7
October	158,000	1.32	82.49	...
September	135,760	1.30	82.94	...
August	169,100	1.38	81.51	25.0
July	150,403	1.24	80.64	24.0
June	164,800	1.06	79.25	22.0
May	175,215	1.40	82.85	24.0
April	165,930	0.94	78.71	19.8
March	162,796	1.03	77.47	20.3
February	122,856	1.02
January	119,914	1.42
Total and average	1,888,869	\$1.23	81.00	22.0

The profit is estimated at \$566,000, less \$180,000 for 6% interest on \$3,000,000 bonds. In 1915 the tonnage was 1,115,294, averaging \$1.15 per ton.

ARIZONA

BISBEE. During December the Shattuck-Arizona mine yielded 1,419,339 lb. of copper, 285,404 lb. of lead, 16,352 oz. of silver, and 249 oz. of gold. The last three metals vary in quantity from month to month.

GLOBE. During 1916 the Iron Cap Copper Co. produced 1,629,897 lb. of copper and 60,027 oz. of silver from 10,360 tons of ore. After paying \$35,329 on January 31 the surplus is \$112,953. Ten feet of 10% bornite and covellite ore has been cut on the 800-ft. level, the most important development of the year.

The Old Dominion Extension Co. at Globe has taken options on several outlying groups of claims, although its original area includes more than 600 acres, much of it patented. Most of the directorate of the present concern will be succeeded by one of the leading copper operators of Arizona and his associates, insuring development of that promising prospect on a scale commensurate with its size and heavy surface mineralization. Although the present management has employed a fair number of men on the property (22 at present), its activity during the past two months has been more in the nature of preparatory work, consisting of road-building to shaft-sites from points where the Arizona Eastern railroad crosses the property, re-timbering and repairing of shafts already sunk on orebodies, etc. On the Iron Mask fault, ore has been developed continuously to a depth of over 100 ft. with steadily increasing value; at a depth of 115 ft. in the Sea Bird shaft a drift has opened the apex of a silver-copper

orebody for a length of 200 ft.; at the Cuprite shaft a silver-bearing iron-manganese ore has been opened to a large extent during the past few weeks, a character of mineralization invariably capping the copper ores of the adjoining Old Dominion property. In the Cuprite workings the silver is already accompanied by copper.

(Special Correspondence.)—The Mineral Hill Mining Co. is preparing to erect a 400-ton concentrating plant at its property. The mine will furnish sufficient water for milling purposes.

The Schaaf mine, belonging to the Vulcan company, is shipping 500 tons of 7% ore per month. This property is owned by J. N. Pemberton and W. R. Ramsdell, and employs 80 men.

The Daily Arizona Consolidated Copper Co., under the management of J. W. Daily, has 15 men on its property north of Tucson. A new wagon-road is being surveyed from the mine to connect with the State highway, reducing the distance from 30 miles by the old road to 14 miles by the new one. The ore averages 6% copper, but several shipments averaged as high as 25%.

The Silver Dike property in the Dos Cabezas mountains is shipping \$50 ore to the El Paso smelter. This property is owned by the White brothers of Dos Cabezas.

William J. Mitchell, general superintendent of the Standard Metals Co., states that the old Mowry mine in Santa Cruz county will be re-opened in January. He expects to employ 150 men. Years ago the Mowry was one of the best producers in Arizona.

W. R. Ramsdell has taken charge of the old Alamos mine, now known as the Pontoc. He is driving a cross-cut into the mountain and is extracting ore containing 7%. Thirty men are working, and a car of ore is being shipped daily. Until a month ago the mine had been idle for eight years.

James Neary, chief engineer for the Magma Extension near Superior, reports a rich strike of ore, running the entire width of the shaft. Assays show the ore to contain \$20 per ton, in gold, silver, and copper.

Tucson, January 3.

OATMAN. The Oatman News has the following to say about this district: "Despite all the alleged unfavorable conditions which should militate against gold mining and in favor of other metals, the Oatman district has more men at work and more properties active than at any time since last May. Actual development has been started upon fully a dozen properties within the past three weeks, and several more are preparing to join the active list. The new United Eastern 200-ton mill will commence to crush ore before the first of the year, giving Oatman one of the most modern plants and creating a new feeling of stability and confidence for the entire district. Preparations for the construction of the new plant to be added to the present mill of the Tom Reed company are being rushed, and it is hoped that the new unit will be in operation by May 1 of next year, as earlier deliveries of machinery and equipment are being secured than was anticipated. Plans for the Big Jim mill are being hurried to completion, so that the third new and modern plant for turning out bullion will be in active service much sooner than was expected. In addition to the operating properties, where over a 1000 men are now being employed in various capacities, there are hundreds of claim-owners now engaged in doing their annual assessment work, and this gives temporary employment at least to many others. Though Oatman is not enjoying or suffering from a boom,

the camp is bristling with good, honest, legitimate activity that presages better and sounder conditions than ever before."

The Big Jim mine at Oatman has been examined by H. V. Winchell, whose report is summarized as follows for the Oatman Bureau of Mines:

The tonnage and value of the ore already developed in little more than a year must be considered as exceedingly gratifying. There will certainly be more ore developed in all directions from the present openings. It has already been started, and good samples were taken on the 240-ft. level, although for lack of development no ore is estimated above a depth of 350 ft. The vein is strong in both east and west faces on the 400 and 485-ft. levels, and only needs further opening to increase rapidly the ore reserves. The work of driving should be pushed toward the north-west for two reasons: first, because the Big Jim holdings extend much farther in that direction, and second, because the ore-shoots rake in that direction

orders, issued by the Industrial Accident Commission, require that steam boilers operated in the State shall be subject to regular internal and external inspections each year. Air-pressure tanks are required to have an inspection not less than once every two years. Committees of employers and employees assisted the Commission in preparing the Orders. Section (c) of Boiler Safety Order 800 reads as follows: "Whoever owns or causes to be used a boiler subject to inspection shall report the location of such boilers to the Industrial Accident Commission of the State of California on January 1st, or within thirty (30) days thereafter, of each year." The Boiler Safety Orders provide rules and regulations for the fittings and appliances that must be used on existing installations, and also provide specifications to which new boilers must be built. These specifications are reproduced from the American Society of Mechanical Engineers' Uniform Boiler Code.

Air-Pressure Tank Safety Order 900 reads as follows: "Who-

THE BIG JIM, ONE OF THE COMING MINES OF OATMAN, ARIZONA.

in the vein. There is no reason to question the existence of the vein in the Big Jim property for 1500 ft. farther to the north-west, and in that direction it is constantly approaching the Tom Reed and United Eastern mines, which as already stated are on branches of the same vein. A level at the depth of 600 ft. will in all probability double the value of the estimated ore, and is likely to encounter some of the Bonanza shoots for which the district is famous. The cost of mining and milling is also likely to be lower than the figure used in this report. Labor and supplies are now at a higher point than for many years, and will probably be lower by the time a mill should be constructed and in operation. Different engineers would probably arrive at different estimates of the tonnage and value of the ore already developed, and many estimates might be higher than that herein presented. Mr. Winchell says that his estimate is intended to be fair and safe, and represents his best judgment. The Big Jim is a real gold mine. It is in a proved district, it adjoins rich properties, and has a vein of unusual size. It has a good quantity of pay-ore already developed and a very promising future.

The United Eastern mill started work on January 4.

STODDARD. The Copper Queen Gold Mining Co. is making preparations to resume operations. Claude Ferguson has recently taken charge.

CALIFORNIA

On January 1, 1917, Boiler Safety Orders and Air-Pressure Tank Safety Orders became effective in California. These

ever owns, uses or causes to be used, any air-pressure tank which carries twenty-five (25) pounds or over pressure per square inch, shall report the location of the same to the Industrial Accident Commission within ninety (90) days after these Orders become effective." Safety Orders for air-pressure tanks contain provisions for the fixing of allowable pressures that may be carried and for certain fittings and appliances which are necessary on existing installations. With a few exceptions the specifications and regulations relating to the material and construction of new boilers in accordance with the Boiler Code are to govern the construction of all air-pressure tanks over twenty-four (24) inches in diameter.

The Industrial Accident Commission has also issued Safety Orders effective January 1, 1917, covering electrical utilization and trench construction. The Electrical Utilization Safety Orders cover safety standards for equipment, storage-batteries, transformers, lighting arresters, conductors, switches, fuses, switchboards, motors and motor-driven machinery, arc-welding, lighting fixtures and signs, portable devices, cables and connectors, etc.

The Trench Construction Safety Orders give standards for sheeting, shoring and bracing trenches, and define where they will be required. Copies of any or all of these Safety Orders may be obtained upon application to the Safety Department of the Commission, at 525 Market street, San Francisco, or Room 423 Union League building, Los Angeles.

AUBURN. Dredging on the north fork of the American river will soon begin. The Guggenheims have leased on a percent-

age basis the claims of several owners along the river for 12 miles. A large portion of the property to be dredged belongs to the Central Pacific Railroad Co. and the Pacific Portland Cement Co.

BAGBY. There is more activity in this district of Mariposa county than usual. The U. S. S. R. & E. Co. has taken the Mary Harrison claims under bond and lease, and has three shifts clearing out old workings, also sampling.—At the Virginia, concentrators were installed in the 10-stamp mill. Within 30 days two carloads of concentrate was sent to the Selby smelter, netting \$51.15 per ton.—At the Red Bank the new flotation plant is being tried. Wilfley tables have been installed.—It is reported that the Mariposa Grant people will extend the 3500-ft. adit at Bagby another 1200 ft., and then cross-cut. Prospectors and lessees are busy on the estate, but no company work has been done for some years.

(Special Correspondence.)—The Headlight electric power-plant, which has been supplying power to the dredges at Trinity Center for several years, and which was owned by Atkins, Kroll & Co. of San Francisco, has been sold to the Oregon-California Power Co. The plant will continue to deliver power, but will be connected in parallel with the Oregon-California power line, which will carry the peak load. The Oregon-California line was brought into Trinity county from Yreka by way of Castella last year for the purpose of supplying power to the Pacific Gold Dredging Co.'s boat lately completed, to No. 2 dredge to be constructed this year, and to the boat to be constructed by W. H. Estabrook at Trinity Center, the present terminus.

Carrville, January 4.

COPPEROPOLIS. The Calaveras property is being arranged to increase the output. The main shaft is to be connected with the Union shaft.

DAMASCUS. The Pioneer mine near here in Placer county is to have a larger mill. The capacity of the old plant is 75 tons per day; with the additional machinery it will be raised to 300 tons. The new mill will be equipped for fine-grinding and cyanidation.

GEORGETOWN. The Darling Consolidated mine in Eldorado county, 8 miles east of this town, is to be equipped with a new modern plant, including a hoist, compressor, mill, and other machinery. W. R. Usher, 42 Broadway, New York, is interested.

HAPPY CAMP. The Gray Eagle Copper Co., a subsidiary of the Mason Valley Mines Co. of Nevada, is reported to have bought the Ely group of claims near here, and work will be started as soon as the weather permits. The Gray Eagle company has completed a three-mile road, and is taking in equipment over it.

HORNITOS. The Ruth Pierce mine five miles east of here, in Mariposa county, has been in operation for three months after a long idleness. It was at one time a substantial producer, and indications are favorable for it again becoming important, as each succeeding monthly clean-up is larger than that before. George McMahon is manager.

LAST CHANCE. The Glen Consolidated drift mine near here, in Placer county, is working although completely buried beneath the deep snow. All buildings and the entrance to the mine are connected by covered passages, and the snow has blanketed mine, buildings, and the entire country to a depth of several feet. There are 50 men employed. The mine is operated all year round, notwithstanding the snow.

OROVILLE. M. F. Reed and J. T. Tallivand have a lease on the Wagstaff mine in Butte county, and are preparing to unwater the old workings.

MOKELEUMNE HILL. The Esperanza mine, 2½ miles north-east, has been sold and is to be re-opened. The workings are 1000 ft. deep.

MOUNTAIN RANCH. It is reported that rich gold ore has been found in the Shenandoah mine, on Jesus Maria creek, near

here, in Calaveras county. This old mine was re-opened last year after a long idleness and is now being operated by the Amapalo Gold Mining Co. The strike was made near a raise cut to get into the region of old stopes that formerly produced a good grade of ore. The mine is equipped with a 10-stamp mill, and will probably add a cyanide plant the coming spring.

(Special Correspondence.)—An encouraging development was made at the Central Eureka mine this week, the shaft, during sinking, having cut ore that assays over \$30 per ton. The entire bottom of the shaft is now in ore. This shoot comes in from the hanging wall, and its discovery at this time is not only gratifying but unexpected, as the intention was to have stopped sinking at about the present depth, and to have started a cross-cut to strike the ore on a level 150 ft. below 3200 ft. Before the resumption of sinking on November 20, the shaft was down 60 ft. below the 3200-ft. station. Progress of 15 ft. per week has been made in sinking since the company let the work on contract, so that the shaft has reached the proposed depth of 3350 ft., including the 90 ft. of new shaft. As the property is being operated at the present time partly on assessments, finding the ore in the shaft without the necessity of running a long cross-cut, means much to the company. The new ore is being crushed with most satisfactory results, and two additional batteries have been started, 30 stamps of the 40-stamp mill now being in operation. When sinking commenced, it was expected that only half of the mill could be kept in operation until the shaft was down and a new level opened below 3200 ft. Fred Jost is superintendent and W. J. Bryant foreman of this property, which lies between the South Eureka and Old Eureka mines.

The Old Eureka shaft has been re-timbered to the 1400-ft. level, and the pumps have been throwing water with such good effect that the shaft is clear for about 200 ft. below that point. A little prospecting is being done on the 800-ft. level, where there is already opened some ore that assays well. The delay in arrival of electric motors, ordered nearly a year ago, impedes progress of surface construction, and little has been done on the new head-frame during the past two weeks, but the electric machinery is expected early next month, and the other work will then be pushed more vigorously.

Sutter Creek, January 12.

COLORADO

CRIPPLE CREEK. During January dividends will be paid by the Doctor-Jack Pot, \$28,441; Cresson, \$122,000; Golden Cycle, \$45,000; Vindicator, \$45,000; and Portland, \$90,000.

GEORGETOWN. Ore from the Imperial mine is being sampled and tested by Mr. Le Brun to determine the best method of treatment. Whatever is decided upon, will be installed in the old Waldorf mill.

IDAHO

Three Coeur d'Alene companies have declared initial dividends for 1917, namely, the Bunker Hill & Sullivan, \$163,500 on January 4, Caledonia, \$78,150 on the 5th, and Hecla, \$150,000 on the 20th. The total of 9 companies in 1916 was \$10,925,698. The Hercules led with \$3,000,000, followed by Interstate-Calahan with \$2,789,940, Bunker Hill & Sullivan with \$1,726,750, and Hecla with \$1,555,000.

According to the State mine inspector, Robert N. Bell, the output of the region in 1916 was

Metal and unit	Quantity	Value
Lead, pounds	338,760,000	\$23,001,804
Zinc, pounds	105,221,000	12,668,207
Copper, pounds	1,238,000	331,412
Silver, ounces	11,201,000	7,251,527
Gold, ounces	2,500	50,000
Total value		\$43,302,950

The value is \$10,000,000 more than in 1915.

Wages paid by Coeur d'Alene companies in 1916 totaled

\$7,800,000. Owing to the sliding-scale for lead, the men received \$1,560,000 additional, this being included in the above total.

OROGRADE. The Hogan mine has a large body of low-grade ore being developed and it is expected to begin production by May 1. It is said that the gold-bearing dike runs through the country for two miles. It is the intention to spend \$300,000 in the equipment and development of the property. The mine was worked years ago and has a record of production reaching \$125,000. However, the cost of operations at that time permitted no profit to be made. With modern appliances and methods a substantial profit is expected.

MICHIGAN

HOUGHTON. Wages paid by copper companies in 1916 totaled \$18,900,000. Of this the Calumet & Hecla distributed \$5,502,000, and its subsidiaries \$5,000,000.

MISSOURI

The November bulletin of the School of Mines and Metallurgy at Rolla contains a study on the origin of Missouri cherts and zinc ores. The publication is illustrated with plates showing the rocks.

NEVADA

BELMONT. The Monitor-Belmont mine is being developed steadily, and it is expected that the 100-ton oil-flotation plant will be operated to full capacity during 1917.

The Old Barcelona mine, 7 miles west of Belmont, is again being opened and new machinery installed. Mr. Pike of the Jim Butler at Tonopah is in charge of development and the installation of machinery.

The Belmont Big Four, with mines on Antone creek, 8 miles west of Belmont, has purchased a stamp-mill in Colorado and will ship it to Belmont and add a flotation plant of 100-ton capacity. The company is selling 100,000 shares at 2½c. each cash, and 200,000 shares at 5c. per share on 10 monthly payments, proceeds to be used in completing mill and flotation plant. The mine has a large vein of molybdenite. Concentrate is worth from \$3000 to \$4000 per ton.

The old Tybo mine, 20 miles east of Belmont, has been leased by the Louisanna company of New York, with a view to treating the dump and opening old workings.

The old Monarch property has been sold to people from Ellsworth, who will move a mill from there to the Monarch.

In a general way it may be said that Belmont is reviving and will be a good district in 1917.

GOLDFIELD. According to George Wingfield, the Goldfield Consolidated is to throw open certain blocks of its mine to lessees. The policy which in the future will be followed by the company in granting leases will be the split-check system, in which the company supplies machine-drills, sharp steel, tools, timber, track, rails, and all supplies except powder to the lessees free of charge, and in addition hoists the ore after it has been delivered to the company. A deduction of \$4 per ton will be made from all grades of ore to cover the expense of transportation, sampling, and milling. Ninety per cent of the gold-value, based on gold at \$20 per ounce, will be figured as the net recovered value of the ore. From this recovered value the deduction of \$4 per ton will be made, and the remaining profit will be divided with the lessee. This form of lease will apply to the portion of the company's estate from which ore will be hoisted through the working shafts of the company. On outlying portions of the company's estate and all portions not connected with any of the main workings of the company, a similar but slightly modified form will apply. The lease maps are being prepared and blocks outlined as rapidly as possible, but it will be a matter of a few weeks before all of the details have been arranged.

MINA. The Table Mountain copper district, 12 miles east,

is attracting some attention. Reno people have recently secured a lease on the Clay Peters mine, from which lessees have been extracting ore.

RAND. In this district of Mineral county, 45 miles east of Luning, the Copper Mountain property has been optioned to the Jumbo Extension company of Goldfield. Lessees have already extracted rich copper ore from the mine.

TONOPAH. In the *Miner* of January 6, Jay A. Carpenter tabulates and discusses the cost of mining and milling at Tonopah in 1915. The daily tonnage at the mills varies from 117 to 453 tons each, the grade of ore from \$13.66 to \$19.25, mining cost \$4.11 to \$5.42 per ton, and milling \$2.95 to \$5.02 per ton. The gross recovery is from 81.7 to 92.97%.

The report of Frederick Bradshaw, general superintendent of the Jim Butler Tonopah Mining Co., for the year ended September 30, 1916, contains the following:

Development amounted to 10,428 ft., costing \$7.58 per foot. Ore reserves are estimated at 19,158 tons. The property was considered to have great possibilities under further exploration, and work done brought out valuable geological information for future development. There was sold 46,489 tons of ore, averaging 0.274 oz. gold and 24.82 oz. silver per ton, equal to \$19.78 per ton. The net realization was \$359,387, against \$345,463 in 1915-'16. Total operating costs were \$10.80 per ton, an increase of 40c. This included 83c. for transportation of ore to the Millers plant. Dividends (2) amounted to \$343,604. Cash on September 30 was \$267,724.

To the end of 1916 the Tonopah mines have produced silver and gold worth \$100,346,899. Of this, \$28,689,240 has been distributed to shareholders.

The Belmont company's profit in 1916 was \$1,151,482; that of the Extension was about \$765,000.

The Diamondfield Black Butte Co. is about to begin the development of the Orizaba silver mine, 40 miles north-west of Tonopah. The greater part of the necessary machinery is at the mine and it will soon be in operation. Heretofore the best ore has been shipped by auto-trucks to the railroad, and then to the smelter.

NEW MEXICO

It is estimated that the total production of all industries in this State last year was \$200,000,000. Of this, mining contributed \$45,000,000, or over 20%.

(Special Correspondence.)—For the last half of December the Mogollon Mines Co. produced 14 bars of gold-silver bullion and 3½ tons of high-grade concentrate. The company has installed a crude-oil burner under a boiler for heating solutions during cold weather. Tests have demonstrated that oil at 15c. in Mogollon is cheaper than wood at \$9, and since the actual price of the latter is \$12 per chord, the saving is appreciable.

Another pack-train has been added at the Pacific mine to move an old ore-dump from the portal of the adit to the terminal of the wire-rope tram to the Socorro company's mill, at which latter point the product is being treated. The tramway is giving entire satisfaction.

The Queen lode is receiving further attention by work just started north of Cooney on the Admiral Dewey-Apache group, comprising over a mile of the vein, owned by Spokane and Canadian capitalists.

Mogollon, January 2.

SOUTH DAKOTA

DEADWOOD. J. T. Milliken, who is already interested in this district at the Ora Hondo, is to resume work at the Montezuma and Whizzers property in Deadwood gulch, near the town. Large quantities of pyritic ore is known to exist.

UTAH

Owing to the cold weather and large snow fall there is reported to be more difficulty this winter in unloading ore from cars than ever before. Smelters receive carloads of ore frozen solid. Concentrates from Idaho also arrive frozen.

The Mineral Mountain range in Millard and Beaver counties is reported to be busy. There are 20 properties being developed, some of which are shipping ore, while others have good prospects.

ALTA. The snow has been cleared from this district, and after a week's suspension ore is again being sent to smelters. The mines are generally in good condition, but the winter is hindering work.

BINGHAM. The Utah Apex Mining Co. reports that for the 6 months ended November 30, 1916, the net profit from \$636,059 gross receipts was \$144,366. In June the profit was \$43,665, in November, \$10,536. The ore available for milling was reduced to a small quantity, but development was increased threefold, and prospects are brighter. A smelting contract made early in the year entailed heavy charges. Zinc-iron middling is to be sold on favorable terms to the Zinc Concentrating Co.

TINTIC. Salt is used (150 tons per week in treating 1400 tons) during the roasting of ores at the Tintic Milling plant, but owing to storms delaying deliveries the works were closed for several days last week.

On January 25 the Iron Blossom company pays 10 cents per share. The treasury contains \$220,000. The output of 200 tons daily is sent to the Tintic Milling plant.

On January 25 the Dragon Con. pays 1 cent per share, equal to \$18,750.

The new hoisting outfit at the Tintic Standard mine is in successful operation. The shaft is to be sunk from 300 ft. to a depth of 1000 ft. This new shaft is 1700 ft. from the original shaft, and from which a large orebody is being developed on the 1300-ft. level. It is believed that this orebody extends to the new shaft and will be cut by it in sinking.

WYOMING

CHEYENNE. Bulletin No. 13 of the Geologist's Office is by Victor Ziegler, and discusses the Pilot Butte oil-field in Fremont county. The oil is of high-grade paraffin base. Possibilities of future development are considered good. A deep test well is to be drilled, and a pipe-line is to be put down to the railroad, 33 miles.

CANADA

BRITISH COLUMBIA

GOLDEN. Ten feet of 24 to 33% copper ore has been uncovered by J. W. Conner in his Tennessee claim in the north-east Kootenay district. Shipments are being made.

PRINCETON. It is reported at New York that the Canada Copper Corporation, which has a smelter at Greenwood, may construct a 13-mile railroad and 2000-ton mill near Princeton. The ore will come from the huge Copper Mountain property.

SILVERTON. Rich lead-silver ore has been opened in the lower level of the Echo mine, and exploration has followed the shoot 85 ft. to a depth of 600 ft. Some of the ore contains zinc and gray copper. The company is considering the erection of a mill. J. H. Thompson is manager. Seattle people are interested.

TRAIL. The reduction works of the Consolidated Mining & Smelting Co. of Canada have been described recently in detail in this journal, and the report of the company for the year ended September 30, 1916, contains the following information:

At the mines (17) there were no extraordinary occurrences, the usual policy of keeping development (18,519 ft. and 20,975 ft. of drilling) well advanced being maintained. The smelter treated 447,017 tons of ore, yielding 98,314 oz. of gold, 2,285,631 oz. silver, 39,974,411 lb. of lead, 4,446,080 lb. of copper, and 3,088,199 lb. of zinc, mostly electrolytic metal. Sales of products realized \$7,203,807. The profit was \$996,496. Dividends absorbed \$776,338. Ores, metals, etc., on hand total \$2,682,934. Cash amounts to \$190,742.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

N. H. RUBY is at Nogales.

F. L. SIZER is now at Reno.

T. J. JONES has returned to London from Siberia.

J. F. MITCHELL-ROBERTS has arrived here from Korea.

H. C. HOOVER is due to arrive today at New York, from London.

IVAN RAGAZ, operating in Coahuila, Mexico, is in San Francisco.

W. F. STEVENS, of Lovelock, Nevada, visited San Francisco last week.

C. M. WELD has removed his office to No. 2 Rector street, New York City.

W. D. THORNTON is visiting the Inspiration and other copper mines in Arizona.

ROBERT HAWKHURST, JR., is now manager for the Eden Mining Co. in Nicaragua.

EARL B. CRANE, of the Black Butte quicksilver mine, Oregon, was here during the week.

DAVID T. DAY passed through San Francisco from Los Angeles on his way to Wyoming; then to Washington.

R. C. GEMMELL, manager of the Utah Copper Co., has been in San Francisco, in consultation with D. C. JACKLING.

ELLARD W. CARSON is now superintendent of the Oceanic quicksilver mine, San Luis Obispo county, California.

W. H. SHOCKLEY has been elected chairman of the San Francisco section of the American Institute of Mining Engineers.

E. T. MCCARTHY has returned to London from a visit of inspection to the Spassky and Atbasar copper mines in Siberia.

E. W. MILLS and J. F. MANNING attended the recent meeting of the local section of the A. I. M. E. They are going to China shortly.

ROY F. HEATH has resigned as chemist for the U. S. Mining Co. and has opened an assay-office at White Sulphur Springs, Montana.

FREDERICK G. CLAPP, of New York, addressed the Geological Society of America at Albany, N. Y., on December 28, on the 'Ethics of the Petroleum Geologist.'

M. H. SULLIVAN has resigned from the staff of the Consolidated Mining & Smelting Co., at Trail, B. C., to become superintendent of the New Bunker Hill smelter, at Kellogg, Idaho.

H. F. DEXTER, secretary and treasurer of the company publishing this paper, fell from the second story of his home at Alameda, while under the effect of an attack of vertigo, on the morning of January 14. He broke a leg and an arm and lies in a serious condition. The accident has aroused keen sympathy in this office and outside.

JOHN D. POPE, who was in charge of the mining operations of the North Butte Mining company at Butte from its organization until 1916 and was general manager for the last six years of his connection with that company, has been appointed general manager of operations in Montana for the Boston & Montana Development Company.

The UNIVERSITY OF CALIFORNIA announces that on January 18, 19, 21, 23, 25, and 26, at 8 p.m., Robert A. Millikan, professor of physics in the University of Chicago, will lecture on electricity, X-rays, the electron, Brownian movements, the atom, and radiation.

The new buildings for the TEXAS SCHOOL OF MINES, at El Paso, to cost \$100,000, are being designed. They will be erected at the foot of the Franklin range. The style of architecture is Bhutanese, and the material will be of stone and concrete.

THE METAL MARKET

METAL PRICES

San Francisco, January 16.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	35
Pig lead, cents per pound.....	7.75—3.75
Platinum, soft and hard metal, per ounce.....	\$85—91
Quicksilver, per flask of 75 lb.....	\$80
Spelter, cents per pound.....	13
Tin, cents per pound.....	42.50
Zinc-dust, cents per pound.....	18

ORE PRICES

San Francisco, January 16.

Antimony, 50% metal, per unit.....	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	15.00
Magnetite, crude, per ton.....	6.50—9.00
Manganese, 50% (under 35% metal not desired).....	16.00
Tungsten, 60% WO ₃ , per unit.....	18.00—20.00

New York, January 9.

Tungsten: Sales have been made in the week at \$17 to \$17.50 per unit. In stating that the Western price basis is lower than that at New York, a broker explains that the firmness in the East is due to the fact that sellers have a wider market, selling for export as well as to domestic consumers.

Molybdenite: The market is quiet and unchanged at \$1.75 to \$1.85 per lb. MoS₂ contained.

Antimony remains exceedingly dull with hardly any business to speak of. The quotation for forward antimony is 11¼ to 12c. in bond, with spot duty paid antimony quoted 14 to 14½c. Needle antimony is offered at 10 to 11 cents.

EASTERN METAL MARKET

(By wire from New York.)

January 16.—Copper is quiet with little offering. Demand for lead is awakening and is stronger, at 7.50 throughout the week. There are few sellers of spelter and buyers are bidding higher. Platinum is offered at \$90 for soft and \$96 for hard.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

June13.60	19.75	27.47	Dec.12.75	20.67	32.89

December production of Cerro de Pasco totaled 5,500,000 lb. of copper, against 5,700,000 in November, 6,000,000 in October, and 5,800,000 in September.

Mohawk Mining Co.'s banner year resulted in earnings better than \$2,000,000 in 1916, equal to over \$20 per share. A new monthly record was also made in December with production of more than 1000 tons of mineral. The February semi-annual dividend is announced at \$10 per share.

November output of Ray Consolidated Copper was 7,161,436

736, against 7,590,038 lb. in October. Ray contributed 15,000,000 lb. to the increase in 1916 over that for 1915. At the outset of 1916 the company turned out copper at the rate of 50,000,000 lb. per annum, while it closed the year on the basis of 85,000,000 lb. per year.

Work is suspended on new leaching plant of Utah Copper Co. owing to cold weather. General Manager R. C. Gemmell says the plant will be completed by the time machinery is delivered from the East. Utah copper is handling 20,000 tons of ore daily. While this is the normal capacity of the plants, the production reached as high as 40,000 tons per day last year and averaged slightly more than 31,000 tons daily. The December production of less than 15,000,000 lb. was the smallest during 1916.

In December Anaconda produced 29,000,000 lb. of copper; the total for 1916 was 336,900,000 lb. Shattuck-Arizona, 1,419,333 lb. Production of the Braden company was 4,716,000 and Kennecott 6,800,000. In December, Chile Copper turned out 6,118,000 lb. and Greene-Cananea 4,975,000 pounds.

Labor troubles are curtailing refinery production in New Jersey.

PLATINUM

Price of platinum, New York, is \$90 per ounce for soft metal and \$96 for hard.

Eastern Metal Market

New York, January 10.

A sharp decline in the quotations for re-sale copper appears to have come to a halt, leaving prices nominal for the reason that they are no longer attractive to sellers.

Zinc is lower under pressure to sell, some of which is attributed to German interests who believe that the War will be ended soon.

Lead has been dull, but firm.

The tin market has been quiet except on two days when buying was active.

Antimony continues dull.

The figures of the United States Geological Survey indicating increased production of all the metals had no serious effect on the market, although it is everywhere recognized that the larger production must be reckoned with after the War, and possibly before its end. While unconfirmed, the rumor persists that both copper and zinc are being offered by representatives of the Central Powers who are convinced that the end of hostilities is near. Another conjecture concerns the possibility of Great Britain having some of the metal she purchased, delivered against her munitions contracts in this country, instead of its being exported in unwrought form. All of this guesswork indicates the extent of the uncertainty which prevails.

The specifications which the steel mills are receiving show no diminution, but consumers are more reluctant about placing orders for second-half delivery, nearer than which there is nothing available, except odd lots at premium prices. This situation does not pertain to plates or rails. Shipyards the world over are seeking plates in the United States, and some have placed orders into 1918. Shell orders apparently are a thing of the past, the Allies having failed to take advantage of options they had with American firms. Canada, as intimated a week ago, is steadily putting herself in better shape to handle the munitions requirements of Britain.

Foundry pig iron is dull but strong. Steel-making iron continues in heavy export demand. The metal-working machinery trade continues under great pressure.

COPPER

Offerings of re-sale copper have been made in the past week at steadily declining quotations with the result that the market has reached a level where prices are no longer attractive to sellers. Extreme dullness and nominal prices is the condition today. Prompt electrolytic was quoted yesterday around 27.75c. to 28c., with persistent rumors that it could be had for less. First quarter was quoted at 27c. to 27.50c., and second quarter at about 26c. Lake was at the same level. The situation is an uncertain one, and theory is taking the place of facts in efforts to explain conditions. One story that is heard, but which has not been confirmed, is that representatives of the Central Powers, confident of the early termination of the War, are selling metal for which they are known to have paid 18c. to 20c. several months ago. On the other hand, it is known that consumers who were induced to gorge themselves with copper, largely through fear, are now anxious to sell their surplus. It is believed, however, that prices have reached a point where these consumers would suffer a loss if they sell, and that this accounts for fewer offerings in the past day or two. The producers are doing no business. There is no question of their being well sold up over the first half. They are not quoting for the last half, at least at prices that will win business. For them to make prices comparable to those which the second hands have been making for the first half would be a confession of the weakness of the market, and might induce cancellations of contracts. It is not improbable that there will be cancellations, or, at least, requests for postponement of

deliveries, and, needless to say, their position is not altogether a comfortable one. A possibility that some of the trade is considering, is the likelihood of Great Britain having some of the metal it has under contract delivered against its munitions contracts now being executed by American firms. All of this is conjecture. The London quotation for spot electrolytic yesterday was £143 against £145 a week previous. The exports, January 1 to 10 totaled 6162 tons.

ZINC

The market has been hard-hit this week, and allegations are frequent that a deliberate effort was made to depress the market. However that may be, the fact is that quotations are lower, and that zinc is easily obtainable at the lower prices. On Monday of this week a broker on the floor of the New York Metal Exchange offered January delivery at 9.25c., St. Louis; February at 9c., and March at 8.75c., 60 tons of each. No one was interested, and later the offering was criticized as not being *bona fide*. The critics were invited to attend the Exchange the following day, and again the metal was offered at the same prices, with the result that it was taken. More zinc was offered at the prices named than was wanted. The New York quotations are 1c. higher. In zinc, as with copper, it is suspected that certain German interests are trying to unload at prices that will net them a profit. While the figures of the Geological Survey, indicating increased production in 1916, have done little harm to the market, they did little to help it. It is hoped that Great Britain will soon buy zinc, inasmuch as she has never bought in quantity proportionate to her purchases of copper. The exports January 1 to 10 total only 1013 tons. The London spot quotation yesterday was unchanged at £50 5s. Sheet zinc is unchanged at 21c. per lb., carload lots, f.o.b. mill, 8% off for cash. It is being much used as a substitute for sheet brass.

LEAD

This metal has been dull, and entirely without feature in the past week. Quotations have been firm at 7.50c., New York, and 7.37½c., St. Louis. The Western market has eased off just a trifle as compared with a week ago. With regard to the statistics, the only comment of the trade is that the increased production is something that must be reckoned with after the War, and possibly sooner. This, of course, applies to all the metals the production of which has been increased. The London quotation yesterday was £30 10s., unchanged from a week ago. The exports, January 1 to 10 totaled only 305 tons.

TIN

On January 4 the market was active, about 300 tons changing hands, and again yesterday (January 9) another 300 tons was taken. Otherwise the market has been dull all the week, but prices have remained fairly firm. The quotation for spot Straits yesterday was 42.50c., and for spot Banca 42c. The feature of the buying on the two days referred to was that the transactions were confined to a few buyers and sellers. It was almost entirely on local account, the tin-plate mills having covered their requirements some months ago. As recently predicted, the brokers and sellers of tin are encountering difficulty in getting specific information concerning shipments from the other side. Agents of the steamship lines sometimes flatly refuse to give information as to sailings or times of arrival, their attitude, of course, being designed to protect their vessels against submarine activities. The arrivals this month total 1520 tons, and there is afloat 4333 tons. New projects for the smelting and refining of Bolivian ore are in motion, more of which will be said next week, after details can be secured.

EDITORIAL

T. A. RICKARD, Editor

THE index to Volume 113 of the MINING AND SCIENTIFIC PRESS is now ready for those that ask for it.

THOSE that are interested in Mexican affairs should not fail to read the long article from our own correspondent appearing in our last issue. We omitted to draw attention to it last week, but it was a most timely and informing contribution.

BUSINESS proceeds with persistent momentum, but recent events have given a salutary check to exuberant buoyancy. Between fear of peace and dread of prolonged warfare we are learning to take short views of life. The rising cost of living has compelled even the most thoughtless to pause and ponder over the state of the world.

ANNOUNCEMENT is made that the American Smelting & Refining Co. is to undertake the manufacture of chemicals on a large scale. The sulphuric-acid plants attached to the company's smelters in the Salt Lake valley are to be greatly enlarged and other kinds of chemicals are to be produced at other plants to be erected elsewhere by the company.

SOME natural curiosity has been expressed as to the source of the \$979,000,000 of gold that has been imported into the United States since the War began. There should be no mystery. The gold mines in the British and Russian dominions together produce \$325,000,000 worth of gold per annum. In 2½ years the aggregate contribution would be \$812,500,000.

INTELLIGENT anticipation is an essential part of Stock Exchange activity. That is why the doings of the share market are held to foreshadow coming events. Those that gamble on the effect of such events are bound to take pains to ascertain what is happening or is likely to happen. The Lawson bid for notoriety is not needed to assure us that information does 'leak' to Wall Street. Statesmen consult with bankers, and even Presidents must discuss matters with other people. Only an autocrat can plan great measures in absolute secrecy.

DAVID H. BROWNE never fails to illuminate any subject he tackles; that is why we reproduce sundry recent remarks of his on the metallurgy of copper. To write well on any subject one must know a good deal about other subjects, otherwise the writing may have the necroscopic character of a catalogue. We found that Mr. Browne's text was much too good to require any editing,

but a sprinkling of hyphens helped to make it clearer. Whether the service of hyphens in technical writing is disdained by Mr. Browne or by our friend Mr. H. Mortimer-Lamb, the editor of the Canadian Mining Institute, we do not know, but we commend the matter to the attention of both.

COMMENT appears in the non-technical papers concerning the issuance of statistics for 1915 by the U. S. Geological Survey at the beginning of 1917, it being argued that this misleads people into supposing that the figures refer to 1916. Apparently our contemporaries are unaware that the final review for 1915 and the preliminary figures for 1916 are issued at about the same time, because the Public Printer is over-crowded with work.

YVES-GUYOT, the French economist, has expressed the belief that a rise in the price of all raw materials and manufactured articles will follow the ending of the War. After the Crimean war, which ended in 1856, there was a marked increase in the cost of metals; after our Civil War, in 1865, many of the metals rose in value for several years, despite a decline in wheat and cotton; after the Franco-Prussian war of 1870 the index number of iron rose from 87 to 141 in three years and the value of other metals was enhanced. The re-construction after war, and the postponed construction also, is a large factor in stimulating a demand for the metals.

SPEAKING of delirious trimmings, we note a sophomore editorial in one of the two San Francisco morning newspapers that victimize this community. It relates to the ore of the Loretta mine, near Bishop. We quote as follows: "Our silicates are said to average 5 per cent, which is now well above the average for copper mining of all classes in America, but, while the dry, the wet and the electro-metallurgical methods have been successful in treating the sulphuretted compounds, the oxides and carbonates, each has presented problems when applied to our silicious formations." The writer of this flapdoodle evidently got hold of two or three technical terms that he did not understand and made a verbal salad of them. Presumably the average reader of the newspaper thought he was receiving scientific information, but it was as delusive as the record of suburban trivialities that loom so large in the daily history of events as furnished to us by an irresponsible local press.

AT Columbus, a city a few miles north-west of Galena and Baxter Springs, mining towns in south-eastern Kansas, prospecting by drill is about to begin in search

of zinc and lead ore, under the impression that the ore-zone underlies that part of the country. The undertaking is in the hands of the business-men of the town; they have organized the Columbus Development & Mining Co., with a capital of \$10,000. This company consists of 40 members, each of whom has agreed to subscribe \$240—\$20 in cash and \$20 each month for 11 months. This is a safe and conservative method of exploring and developing the resources of any region where there is a possibility of discovering mineral by intelligent prospecting. It is not always easy to interest outside capital in local exploration; realizing this, the wide-awake business-men of Columbus are wise in undertaking the job themselves. Their courage is deserving of reward, although a careful geological investigation by competent men should first be made to determine whether or not their scheme is one possessing the elements of success.

PENNY postage is the subject of an active propaganda.

We sympathize with any effort to facilitate human communication, but we note that the campaign for a reduction of ordinary letter-postage is accompanied by the proposal to establish a zone system of rates for second-class matter, which includes periodicals of nation-wide circulation. For distances up to 300 miles the postage on second-class matter is to be 1 cent per pound, between 300 and 600 miles, 2 cents per pound of printed matter; between 600 and 1000 miles, 3 cents; 1000 to 1400 miles, 4 cents; 1400 to 1800 miles, 5 cents; and over 1800 miles, 6 cents per pound. At present the rate is 1 cent per pound across the whole length and breadth of the country; the increase therefore to 6 cents, to be paid by magazines and journals coming from New York or Boston to the West, would be prohibitive. The impost would not affect us heavily because the larger part of our clientele lives within 1000 miles from this office, but it would kill many national magazines and place a confiscatory embargo on a big industry established under the law and entitled to just treatment from the legislature and from the community. Any such rates on periodical literature would be a blow to education so stupid that we refuse to believe that the proposal will be sanctioned by Congress.

AT the recent annual meeting of the Minerals Separation in London, Mr. Francis L. Gibbs, who acted as chairman in the absence of Mr. John Ballot—then at New York—made sundry references to the legal victory won by the company in the Hyde case. He stated that the licensees of the company in the United States treated 11½ million tons of ore and paid \$700,000 in royalties during 1916. That indicates an average royalty of about 6 cents per ton. He also stated that “the very numerous infringers” treated 13½ million tons during the same year. As to the taxation of the ‘infringers,’ he said: “It is, however, unreasonable to suppose that those who in the future will control our American interests will charge those who have been infringers of our process the same exceptionally favorable terms which were granted to large users like the Anaconda Copper Company be-

fore our patent position was established. We shall not, you may be sure, act otherwise than reasonably and equitably even toward infringers, but it is obvious that those who for the past three years have been making enormous profits by the unlawful use of our process must be prepared to hand over to us at least a considerable proportion of these profits. It is estimated that by means of our process these infringers have made profits of more than £5,000,000 [or about \$25,000,000] beyond those which they could have made without our process, and by the American law we are, I believe, entitled to claim the whole of the excess.” The report of the meeting in the *Financial Times* says that these remarks were received with “laughter and applause.” The sense of humor is not dead in London.

A Superintendent of Mines

Mining is full of romance, but much that passes for such is tawdry fiction. The accidental discoveries of rich ore made by ignorant men to whom wealth brought merely the opportunity for unlimited debauchery are often allowed to masquerade as romance and the piling of millions by unscrupulous gamblers is not infrequently glorified into masterful finance. In this issue we publish an interview with a real miner and in the course of that interview he, John H. Mackenzie, gives us the outline of an adventurous career. The story is truly romantic because throughout there is disclosed the development of character and the growth of natural abilities that were put to useful purpose, culminating in wealth—of course—but also in things much more difficult to win—the reputation for engineering skill and the goodwill of his fellow-men. From the boy that ran away to sea and then penetrated into the lumber camps; from the youth that heard the call of the West, and the resolute man that braved the perils of the Klondike rush, we see emerge the captain of industry. From his father, who was a mechanic—“and a good one”—he inherited some liking for machines and the working of them, for he himself was a good mine-mechanic before he was a miner; he became an efficient timber-man and an expert pump-man, and through these fundamental experiences he learned to understand the more complex machinery of the mine and mill, so that in early manhood he was well equipped to direct the multifarious operations of a big enterprise. We are not of those that believe that every graduate student in mining engineering should devote several years to manual labor underground, simply because we know that many youths have not the robust physique—the toughness—necessary for the performance of such work without at the same time dulling their mental faculties, but we are among the first to acknowledge that if a young man has indeed got the spirit and the stamina to undergo this severe training he will emerge a more capable leader of men. Mr. Mackenzie underwent such a training and in consequence of it he acquired a thorough knowledge of basic operations underground; he had the nerve and the strength to go

through the hard grind of physical labor and of junior supervision, thereby gaining a closer understanding of the realities of mining work than is the portion of the young man that graduates to superintendency or management from the assay-office or the survey department. Few, if any, of those at the top of the mining profession have so intimate a knowledge of conditions underground. Moreover, the close contact with the drill-men, the shovelers, the trammers, and the timber-men has given him an appreciation of the human factor, which is at least as important as the mechanical. That was demonstrated in his successful handling of the strikes at Goldfield and at Rossland. He obtained 'bedrock' experience early and, as he says, he has "been getting it ever since."

When he went to New Mexico and the Indians stood in the way, he did not return, but "kept going." When only 23 years old he sold some mining claims and first had the feeling of financial independence. His wanderings in Arizona, New Mexico, Nevada, and Montana did not lead anywhere in particular, but the engineering done on the water-works at Eureka gave him a reputation as a pump-man and led to his first charge of a mine, near Deadwood. Soon came the lure of Cripple Creek and the meeting with Stratton. That was a decisive event in his life. As that versatile poseur Thomas W. Lawson has said: "Fate hangs no red lights at the cross-roads of a man's career." Stratton stood at the right turning, and from the moment when Mr. Mackenzie was engaged by him as superintendent of the famous Independence mine he never looked back. The story of the discovery made by Stratton is in accord with our knowledge of the facts and quite different from the meretricious tale that reporters and others concocted when once Stratton became a millionaire. Those Cripple Creek celebrities were an unlovely lot, but Stratton knew how to be generous and the story of his dealings with Mr. Mackenzie does honor to his memory. The squabble between the first owners of the Portland is not enchanting and the use of revolvers only provokes a sarcastic smile, for these antics of the directors of a big mine were childish and stupid. A touch of the fresh strong air of the Far North comes across the page as we read of the expedition to Dawson and of the journey by dog-team from Skagway. Mr. Mackenzie early realized the effectiveness of using steam, instead of wood-fires, to thaw the frozen gravel, and he capitalized his acumen to the tune of \$50,000, by collecting the necessary equipment and then selling it to the men 'on the creeks.' Among his qualities is the ability to get at the bottom of things, a thoroughness of method that is scientific. He has applied this method to affairs other than mining, for his ranch and vineyard at Marysville have been made profitable. Such success is rare among those that turn from the drill to the plough, even for relaxation. Next we come to the Mariposa grant. Many of our readers will be keenly interested in reading Mr. Mackenzie's remarks concerning the southern end of the Mother Lode region. Mr. Edward H. Benjamin is now in charge of mining operations at the old Princeton mine, in behalf

of Mr. Hennen Jennings, who is a strong believer in the possibilities of successful exploitation in this famous tract of mineral country. While the association with Stratton proved a turning-point in Mr. Mackenzie's career, it is probable that the most important event was the formation of a working partnership with Messrs. F. W. Bradley and Mark L. Requa. Together these three engineers founded the Nevada Consolidated copper enterprise and together they fought against the financial legerdemain by which the Cumberland & Ely claims were used to mask a tricky deal. The Goldfield chapter is full of lively doings, for, as manager of the principal mine in that district, Mr. Mackenzie had to face a bitter strike and check systematic ore-stealing, besides which he became engaged in the rapid building of a big mill and the working of extremely rich and equally erratic ore-bodies. His ability to hold the confidence and to guide the policies of two such unlike men as Messrs. George Wingfield and W. H. Crocker bespeaks a knowledge of men and a tactfulness that is not all confined to the diplomatic service. The reader will note what he has to say on the labor-union and collective bargaining. He is much too enlightened to evade the issue raised between capital and labor, or to suppose that the 'right' of the wage-earner to organize is to be met by the employer's 'right' to refuse recognition to such organization. That does not mean, however, that he has any use for the anarchistic kind of conspiracy typified by the Western Federation of Miners. He approves Mr. Albert Burch's plan to aid young Americans in obtaining instruction while working at mines; in this and in kindred matters of management he exhibits a humaneness that we know to be no affectation. As to the Alaskan mines and sampling—that is a subject much too big for passing comment. We would like Mr. Mackenzie and Mr. Bradley to follow their excellent report on the Alaska Juneau by writing a paper on the subject of sampling big bodies of low-grade gold ore, but the trouble is that those that know about these matters are disinclined to write on them. To such broad-gauge men, however, the public service performed by such a writing ought to be a real inducement. And so we leave our 'superintendent of mines' actively engaged in big-scale digging, of gold at Juneau, of tungsten at Atolia, and of other metals elsewhere. The interview will be read with pleasure beside many a camp-fire and cabin-stove, for John H. Mackenzie has spread his friendships all over the West. A man of engaging personality, of unaffected good-fellowship, and possessed of the saving sense of humor, he has made friends from the sturdy timber-man stepping into the cage for his day's shift, to the 'malefactor of great wealth' ensconced in the soft upholstery of a limousine gliding over the asphalt toward Wall Street. His success has pleased all of them, for, by birth a Canadian and by life an American, he is the kind of true democrat that socially knows no superior and likewise no inferior. Mining still offers a career to talent. It affords great chances to those that work hard and 'make good.' That is the moral of this story.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Grinding-Mills at the Inspiration

The Editor:

Sir—I was interested in reading the letter from Mr. Van Winkle published in your issue of January 6, criticizing Mr. Cole's discussion on the same subject appearing in the issue of December 9. I was, however, at a loss to understand how Mr. Van Winkle, after carefully reading Mr. Cole's comments on the subject could say, "Does Mr. Cole think that the mining and milling fraternity will accept results as 'conclusive' from him or any one else in which the mills are operated in two separate plants and where the Hardinge mills are crushing in two stages and the Marcy is doing it in one?" Personally, I cannot conceive of a more conclusive comparative test than that contemplated at the Inspiration and referred to by Mr. Cole. The ore to the mills working in competition will come from the same mine and will be drawn to the two different mills from the same bins after the same preliminary crushing; the fact that the Hardinge mills will be used in tandem or two-stage reduction while the Marcy mills will be used in single-stage reduction will in no wise affect the conclusiveness of the result if the tests are extended over a period long enough to obtain reliable data as to maintenance.

Mr. Van Winkle further states, "I am sure the mining public would like to know the difference between the real Hardinge ball-mills that are now being installed at Inspiration and the Hardinge mill equipped with 11 tons of steel balls that was used in competition with the Marcy mill during December 1914 at the Inspiration test-plant." To the best of my knowledge the Hardinge mills in these tests were charged with pebbles and were used as re-grinding mills against tube-mills and not in direct competition with the single-step Marcy mill.

I cannot agree with Mr. Van Winkle when he expresses a doubt as to the contemplated experiments on ore reduction adding materially to our knowledge of crushing, for to me the work of the Hardinge mills at Miami, taking an initial feed of $\frac{3}{4}$ -inch size and crushing to the required fineness in two-stage reduction; the comparative grinding tests at Inspiration of the single-stage Marcy mill working in competition with the Hardinge two-stage reduction, each mill receiving the same size of feed and reducing to the same fineness, will be of exceptional interest. The work of the Symons disc-crushers at the New Cornelia Copper Co.'s plant taking a $3\frac{1}{2}$ -in. feed and reducing to $\frac{1}{4}$ -in. size and the tests of using balls instead of rods as a grinding medium in the

Marathon mills to determine by which method the ore is best prepared for flotation, should also be of more than passing interest.

The above experiments are broad in scope and taken as a whole they cover the field better than any previously tried. The data obtained from these experiments should not only add materially to our knowledge of crushing but should also bring about a decrease of operating cost.

HENRY HANSON.

Misfires

The Editor:

Sir—I have read 'The Prevention of Misfires,' by Mr. E. F. Brooks, which is very good. He gives more causes than most people could imagine existed for misfires; they cause annually a very considerable loss, and anything we can do to curtail that loss will save money and lives. One cause of misfires recently brought to my attention is the absorption of dampness in the end of the fuse, before the cap is put on; frequently you will hear the miners say it was a 'bum' cap, when the cap is all right. The fuse burns to within an inch of the end, and goes out because dampness has penetrated that exposed end. This can be avoided by reversing ends or cutting off an inch or two of the exposed end.

Towle, December 21.

JAMES ROSS.

The Small Shipper and the Smelter

The Editor:

Sir—We note in one of your recent issues that you invite the small mine-owner to write up his experience in shipping small lots of ore to the smelters. At different times this past summer we have shipped small amounts of ore to a certain smelter, and in every case but one our assays have been away yonder over the amounts we received from the smelter, and in that one case—the largest and highest-grade shipment we made—our assays showed the value of the lot to be slightly over \$1100, for which amount we registered the shipment at the express office, and the smelter returns amounted to \$950. This shipment weighed 380 lb., and we have since learned that assays made by an independent assayer on a fair sampling of the ore showed values to the extent of \$10 per pound. And another thing, shipments made through the express company invariably realized nearer our assay

than did shipments made by freight. We wonder if the railroads and smelters don't have some kind of a 'gentlemanly agreement'?

Now, we have good reason to believe that our assays run low, as we have checked pulp with other assayers and in every case our results were under those given by custom assayers. We admit that our furnace is not of the best, and perhaps we lose some values "in the perfumes" as one mining 'expert' put it. Our last shipment of ore, over the railroad, as freight, seemed to us an especially raw deal. It was almost straight hematite, hand-sorted to a clean product, and contained an appreciable amount of coarse gold. Our assays on a fair sampling showed over \$500 per ton, and there was 420 lb. of it. Keeping in mind our uniformly low results in assaying, we figured on from \$100 to \$150 in the lot, but the smelter returns came to \$42. with absolutely no mention of metallics, and we are confident we could have amalgamated \$40 or \$50 from that ore by grinding and panning here at the mine, as we had previously ground and panned several hundred pounds and know almost exactly how much gold there is in that hematite stuff. Our object in shipping it was to save the trouble of grinding it and to avoid the loss of gold in the tailing. Also, the smelter deducted 6.4% of the 420 lb. as a moisture penalty, though when we sacked the ore here it was dry and dusty and was delivered to the railroad in that condition—6.4% on a dry ore. We wonder how they have the nerve, when it is well known that the mechanical filter-press dries a sloppy mud in a few minutes to a product containing from 8 to 12% moisture, and in the Editor's recent article on the Britannia mine, in British Columbia, he speaks of concentrate drained to an 8% product—a damp, if not actually wet material, several degrees removed from a dusty ore.

Now, to conclude, we shipped the ore and received a check to cover same at the smelter's valuation, and we shall have to be satisfied, but you can bet that aggregation of robbers won't get any more of our ore. We'll get a beer-keg and cyanide it, and thereby save all of the values.

LOVEJOYS.

Unity, Oregon, November 27.

How About Contributory Negligence

The Editor:

Sir—Laws having for their object the protection of workmen are becoming drastic and numerous, but among all these there is a conspicuous absence of any law providing a penalty for the carelessness, or contributory negligence, as it is legally termed, on the part of the workman himself. Of the many accidents occurring in mines the greater number is due in some measure, and not infrequently wholly, to the carelessness of the workman himself. Too frequently he is guilty of contributory negligence. He is prone to overcrowd the skip, or cage, if there is no one in authority to restrain him; he will tamp holes with the iron spoon, if no one

is watching, because it sometimes is a little easier, especially in a deep hole, and therefore more quickly done. He will often take evident risks in working down ground because he does not find it convenient to put in the necessary timbers as soon as they should be placed, preferring that someone else do it. He has been known on occasion to push a loaded car carelessly into the shaft at the station without first looking to see whether or not the skip was there to receive the ore. True, this last is of rare occurrence, as in most well-managed and properly-equipped mines ore-pockets are provided beneath the levels at the various stations into which ore or waste may be dumped, to be drawn into the skip at some later time when convenient, but in small mines there are often levels where no such ore-pocket is cut, and the ore is dumped directly into the skip—but it is not customary to dump the ore into the shaft when the skip is not there to receive it.

Mining always involves the element of danger—it is inherent—but the miner becomes so accustomed to it that, after a time, he ceases to give to the usual evidences of danger the serious consideration they require. Old timers are just as liable to injury as those who are comparatively inexperienced. The newer men, not yet callous to the dangers of their calling, and remembering the slogan 'safety first,' give more prompt heed to evident danger, whereas the same sign may be neglected by those long accustomed to underground work. If the laws provided a penalty for many of the forbidden things that workmen do about mines, things that are forbidden by the mine management and by common sense, if not by law, there no doubt would be fewer accidents, for often it seems as if the average miner holds in greater dread the possibility of a fine of a few dollars, for some infraction of a rule, than possible injury or the loss of his life due to breaking this very rule.

In this connection it is interesting to note that the United States Circuit Court of Appeals recently decided in the case of *Macauley v. Alaska Gastineau Mining Co.* that a miner working in a raise where the company had taken all reasonable precautions to insure his safety, assumed the risk of being injured through the falling of rock, in barring-down after blasting. It is also interesting, even gratifying, to observe that the Accident Commission has not always the last word in such cases.

MINE OPERATOR.

Jackson, December 11.

THE JANUARY ESTIMATES of shipments of iron ore from the Lake Superior mines during 1916 are 75,500,000 gross tons, compared to 55,493,100 tons in 1915, according to Ernest F. Burchard of the U. S. Geological Survey. Not only are these record-breaking figures, but the ore sold for \$178,935,000, an increase of over \$77,000,000 compared with 1915. Ore in stock at the mines approximates 10,486,000 tons, compared with 13,748,000 tons in 1915. Production of pig iron also made a record in 1916 with a total of over 39,000,000 gross tons, compared with 29,916,213 tons in 1915.

Platinum in California

By E. F. Brooks

The present high price of platinum has resulted in many inquiries concerning this metal, and particularly where it may be found.

Platinum is produced in northern California and southern Oregon, where it is associated with placer gold. In California it is found from El Dorado county northward, in the districts where serpentine is abundant. It never has been found in this State associated with any other rock than serpentine, and this has come to be considered as the formation in which platinum should be sought. Platinum occurs naturally as an alloy, being combined with iron, iridium, osmium, rhodium, and palladium. The osmium content is generally the greater, being in northern California 1 to 2%.

Platinum does not amalgamate with quicksilver but owing to its great density it is easily arrested by riffles in the sluices. Several years ago, when operating a hydraulic mine at Trinity river in northern Humboldt county, I found platinum more abundant there than in any other district with which I was acquainted, the platinum constituting about 10% of the entire output of the mine. Prior to the commencement of our work at this mine, there had been no mining done in this locality by the hydraulic method, except some small operations by old-timers along the river. They observed the platinum mingled with the gold when cleaning-up and separated it as far as practicable and threw the white metal away, not knowing its value. They regarded it as a nuisance, as it is difficult to separate from the gold, which was in small flat scales and caused some loss of the gold in panning if the greatest care was not taken to prevent it, particularly where no quicksilver was used to amalgamate the gold, and even then it required an experienced panner to effect a close separation of the two metals. As a natural consequence some platinum usually remained with the gold, which was generally sold in small quantities from day to day to local storekeepers. These buyers penalized the miners for the platinum with their gold-dust, so the presence of the more valuable metal resulted in an actual loss instead of an additional profit. Whether the storekeepers received anything for the platinum, I do not know.

Our mine was operated with giants having a 6-in. nozzle under a 300-ft. head; the gravel was free and easily washed, containing few boulders that required bulldozing. Although the gravel was low-grade, the operation was profitable, as the cost of mining did not exceed 2c. per cu. yd. using a 3½-ft. flume set on a 7% grade.

The gold was fine and in thin flakes, though not 'scale' gold. It had evidently been transported from a great distance. The bedrock was slate, but a broad belt of serpentine lay just above the mine, and over this the gravel must have passed. Doubtless the serpentine was the source of the platinum associated with the gold in our mine.

There are thousands of acres of gravel in this district, all of which carries some platinum and most of it enough gold to pay by hydraulicking under experienced management. It is mostly on the public domain and subject to mineral location. The higher ancient channels, some of them 1000 ft. higher than the modern streams, are generally the richer, carrying coarser gold. Some of these channels are admirably situated for hydraulic mining and there are no restrictions on the hydraulic method of mining in this region as the streams are not tributary to the Sacramento valley, but run directly to the ocean. The greater part of the expense necessary to the opening of a mine here will be the creation of reservoirs and the digging of ditches. The building of flumes, pipe-lines, and equipment of camp would be about the same as elsewhere.

GOLD PRODUCTION. In a compilation prepared by the foreign trade department of the National City Bank, some interesting facts are given regarding the world's gold production. The output of this precious metal in the last 25 years equals the total for four centuries immediately preceding this period, and the production of silver since 1878 also equals the output of the 400 years immediately preceding 1878. The gold currency of the world has doubled in the last 20 years, and silver has been reduced one-half in that time. The total production of gold from the discovery of America to the present time is placed by the National City Bank at \$16,500,000,000 in value; and the production of silver at \$15,500,000,000 in coining value. The gold money of all countries of the world, for which statistics were available in 1896, reached a total of \$4,144,000,000. On January 1, this year, the aggregate was \$8,258,000,000. In 1896, the silver money of these same countries amounted to \$4,237,000,000, while in 1916 this had shrunk to \$2,441,000,000. The 'uncovered paper' money—not completely protected by gold—of the countries in question was placed in 1896 at \$2,558,000,000, and in 1916 at \$8,583,000,000. The production of over \$8,000,000,000 worth of gold in the last quarter of a century, compared with \$8,000,000,000 in the preceding 400 years, has taken place chiefly in the last decade. Down to 1885, the world's gold output never reached as much as \$100,000,000 annually. In 1896, it was a little more than \$200,000,000 and in 1903 it for the first time exceeded \$300,000,000. In 1906 the mark of \$400,000,000 was crossed. The chief gold producing countries of the world are South Africa, the United States, Australia, Russia and Canada, while the chief silver producing countries are the United States, Mexico, Canada, and Peru.

FIRST PRODUCTION of lead and silver from the mines of the Coeur d'Alene was made in 1885-'86. It mostly came then, as ever since, from the Bunker Hill & Sullivan mine.

HEROULT electric-steel furnaces to the number of 80 are now operating in the United States and Canada. On January 1, 1916, there were but 43.

John H. Mackenzie: A Superintendent of Mines

An Interview. By T. A. Rickard

Mr. Mackenzie, you are a native son?

No; I am a Canadian, born at Toronto, Canada, on the 24th day of May 1858.

Was your father engaged in mining?

No; my father was a mechanic, and a good one.

What made you take to mining?

The lure of the West, and the high wages.

What preparation did you have?

I had some schooling in mechanics and engineering—not a college course—in the high-school at Goderich, Ontario. When I was 13 years of age, I ran away to sea. I went as an ordinary seaman on a sailing vessel called *The Mechanic*, leaving the port of Detroit for Chicago; after that I made voyages from Chicago to Montreal, and from there to Liverpool and London.

How long did you stick to the sea?

Three years only. I decided that the sea did not offer me a career; I saw no prospect of advancement.

What next?

I went into the lumbering business at Muskoka, in Ontario 200 miles north of Toronto. My work was scouting for timber, measuring and keeping accounts of the timber purchased for Gordon & Co. I had two years at that, learning to take care of myself in the woods. I also learned the difference between good and bad timber, besides having some experience in the wild life of the river.

It was a pretty tough life?

Indeed it was. That was why I left it when the novelty had become well worn.

What date was this?

I quit lumbering in the spring of 1877, and in the fall of the same year I came west to Eureka, Nevada.

What brought you to Nevada?

Reports of men that had returned from there telling of the great camps of Virginia City and Eureka, which, at that time, were at their best.

Eureka, I suppose, was producing a great deal of silver-lead?

Yes; and gold also, for the surface ores contained nearly as much gold as silver.

Did you get a job?

I did. I went to work in the Jackson mine, as a miner, receiving \$4 per day for a 10-hour shift. The work was done by hand, double-hand, that is, using both hands on a hammer while one partner held the drill. Another interesting point is that they were using black powder, although 'giant' had been introduced, and was being used in some of the mines at Eureka.

Who was the manager of the Jackson mine?

William Shaw. He had been manager of the Eureka Consolidated, and he was owner of mines at Eureka until he died.

You were there for some time?

I was there for three years. The second year I worked as a timber-man, and the third year I was pump-man part of the time, and timber-man the rest. In the third

MAP OF NEW MEXICO.

year, when I was 23 years old, I was in charge of the timber-gang.

So you obtained some bedrock experience?

Yes, and I have been getting it ever since.

Do you recall any of your friends at Eureka at that time?

I knew Dr. Zeile, whose name is given to a well-known mine on the Mother Lode, and Hank Donnelly, who was a famous superintendent at Virginia City; also Charlie Canfield, who died three years ago, and was a big operator in oil, associated with E. L. Doheny. Canfield was shift-boss when I was timber-man in the Jackson mine. I also knew Tom Reed, superintendent of the Eureka Consolidated mine and smelter, and your uncle, Reuben Rickard, who was then superintendent of the Richmond; also John A. Porter of Denver. In fact, my next move

was due to Mr. Porter, for he engaged me to go to Colorado as timber-man in the Aspen mine at Silverton.

What sort of a mine was that?

Native silver ore; the vein was worked by adits entirely, the ore being treated locally at the Greene smelter. They charged from \$75 to \$100 per ton for smelting, not to mention other deductions, so that the smelter made money, and even the mine, because the ore used to run from 150 to 300 oz. silver per ton.

You did not remain timber-man long, I suspect?

About eight months. The Black Range excitement broke out in New Mexico, and I stampeded, going on snow-shoes to Durango, then by pack-horse to Santa Fe, and from there down the river to Socorro.

What did you find there?

Many promising prospects; but I did not stay, the danger from the Indians being greater than the prospects of making money, although Chloride Gulch became quite a camp afterward.

When did you return from New Mexico?

I did not return; I kept going. I went down to Tombstone, Arizona, and into the Chiricahua range, where I prospected for silver and located some silver-lead claims. This was the spring of 1881. I spent some time in several mining camps in New Mexico, such as Silver City, Georgetown, Santa Rita (which is now Chino), Shakespeare—by the way, Henry C. Callahan was there at the time, and so was Doheny.

You did not find anything good?

No, but I sold some claims and made a small stake, selling five claims for \$5000, which seemed a lot of money to me then. With that I went back to Tombstone, in the fall of 1881, the year in which Garfield was shot. At Tombstone, I was ill for a time with rheumatism, and then I came to San Francisco, where I regained my health.

By this time you were only 24, but you were more than a sophomore in the college of experience?

I thought I knew a great deal more than I really did. I found afterward how little I knew at that time, but I was full of confidence and ambition, and I had become tremendously interested in the work of mining.

What was your next step?

I went back to Eureka a second time. The Eureka Consolidated was putting down a large new shaft, and erecting a big plant of hoisting machinery and a large hydraulic pump. I went to work for the company, taking charge of a gang of men engaged in installing the new machinery. After the machinery was in place I had charge of the pumping plant from the time it started in the fall of '82 until it shut-down. For two years they kept sinking the shaft and fighting the water, so that I was fully employed and obtained some valuable experience—some of the best experience that I have ever had. The mine became flooded, and the camp practically idle, so I took a lease on the Hamburg mine above the Dunderberg, north of Eureka.

How much money did you put in?

We put in very little money, but a lot of work. We made some money, shipping our ore to the Richmond & Eureka Consolidated furnaces, and then cleaned up. From there I went to Butte, Montana, which was then, in the fall of 1884, on the boom.

What did you do at Butte?

I worked as timber-man for Alfred Wartenweiler, who was manager of the Lexington mine. After a few months I took a lease of the Lavina mine at Burlington and the old Silver Bow 10-stamp mill. I was in partnership with Neil McSherry. We made some money, but the vein played out in depth, and, owing to the excessive flow of water, we could not afford to prospect further. I then went to work for W. A. Clark in his concentrator at Meaderville, and put all the machines there in shape. I was there about four or five months. I knew many of the old-timers, Patsy Clarke, Mike Carroll, the famous superintendent of the Anaconda, Daly's right-hand man. I also knew Jim Murray, besides Marcus Daly himself, but only casually.

What sort of a place was Butte then?

At that time the roasting was done in heaps in Silver Bow flat, and the air was loaded with sulphurous smoke, so that at times people on the street could hardly find their way. The Lexington was down only 450 ft. and the Anaconda was only 800 ft. deep. Silver was an important part of the output, in addition to copper.

From Butte you went whither?

The smoke made my throat so sore that I decided to seek a purer air, and went to San Francisco, remaining there about two months. I was offered a position as foreman of the Jackson mine, the one in which I had first worked. I accepted; that was in '86.

You ran the mine for how long?

Two years. I then leased what was known as the Ruby Hill Water-Works, from Walter Harrub, a famous character in the early days of Nevada. I ran the water-works for two years, but you must not think that there was no mining connected with this job; the tunnels for tapping the water were always caving, so that I was kept busy maintaining them in proper repair. Eureka became very dull again, so in 1891 I went to the Black Hills, in South Dakota.

Did you have an appointment?

Yes, with Franklin R. Carpenter. I had obtained some sort of a reputation as a pump-man and a miner experienced in handling water, thanks to my work at Eureka. Dr. Carpenter ran the old Delaware smelter and had several mines in the district, among the number being the old Oro Fino, which was full of water at this time. They were trying to pump it out. It was about 12 miles from Deadwood. I was superintendent of that property for about two years. The price of silver went down so much in the crash of 1893 that work was stopped.

It seems to me, Mr. Mackenzie, that you and I are in

agreement in one respect. I used to think that a young man could always get all that there was to be learned at any one mining camp in the course of two years. It seems to me that your periods were nearly always two years.

Yes, I made it a point to never stay longer than two years in one camp.

On leaving the Black Hills, where did you go?

I had heard of the Cripple Creek excitement, and went there, meeting W. S. Stratton, the discoverer of the Independence. I found him prospecting on the surface of Battle Mountain. He told me about his discovery; it seemed to be interesting. He wanted to know if I

What smelter rates did you pay?

I think on 5-oz. ore the smelter and freight rates combined came to \$15 per ton.

What sort of a man was Stratton?

A man with a keen mind, but not well balanced. In business he was liberal and fair, but suspicious; he trusted very few people, changed his mind often, and did not understand handling the large sums of money that he was making not only out of the Independence, but also out of the Portland, of which he owned one-fifth. He was very charitable. In his investments he was often foolish, and a great many people took advantage of him.

MAIN STREET OF VIRGINIA CITY, NEVADA.

knew how to run a mine; I told him that I could, and without any further recommendation or acquaintance, he engaged me on the spot. I gave him references, but he never made use of them. He had had six superintendents in the previous three or four months.

That was the time when I first met you?

Yes. I remember a visit that you made with Mr. Tom Stearns to the mine in December '93, when Cripple Creek was having its first boom. The Independence shaft at that time was only 100 ft. deep, and the Washington shaft was 60 ft. deep, with a tunnel uniting them. We were raising the ore with a whim, stoping above the connecting level, and shipping the ore to Denver. I restarted work on the Independence shaft, and kept on sinking it until it was 600 ft. deep. The Independence vein proper was in granite and the shaft was situated near the contact between the granite and the porphyry, hence the vital question at that time was whether the vein would continue into the porphyry. When I first came the ore was averaging five to seven ounces per ton for a width of five to seven feet.

He was not a man of any technical training?

No; he was a good millwright, and had prospected quite a lot, especially around Silverton. His finding of the mine was a matter of luck. He was prospecting on the sunny slope of Battle mountain and he saw the outcrop of the Independence vein, but it looked very much like granite. Several other people had seen it and concluded it was nothing but decomposed granite. All of them passed it by. Stratton himself found that the loose porphyry-rock on the hillside contained gold, but he could find no vein. Finally he chipped off a piece of the granitic outcrop and looked at it through a magnifying glass, detecting some rusty gold. Thereupon he broke some more pieces and had them assayed at Colorado Springs. The sample contained 19 oz. gold per ton!

So you had the pleasure of starting the development of one of the big mines of the world. Did you remain long with Stratton?

Three years. Then I went on a vacation and while I was away the meeting of the Portland directors took place. They were having trouble with water in the Port-

land shaft, and at the meeting of the board, the directors, who were quarreling, agreed to offer me charge of the mine. I accepted. The offer came to me by telegram while I happened to be in San Francisco on my vacation. I returned next day, as they accepted my terms right away. I took charge of the work at the Portland for just about a year.

Then you knew James Burns and John Harnan too?

Very well. At that time Jim Doyle, another owner, and Jimmie Burns were at dagger's points and when they came to the directors' meetings—I was also a director—Doyle would come with the handle of a six-shooter sticking out of his coat-pocket, and Jim Burns was supposed to carry a gun in his hip pocket. It looked like a battle every time they met; I always expected that one of them would kill the other, but no gun-play ever followed, I am glad to say, for my life, incidentally, would probably have been jeopardized also. Stratton used to sit back in the corner with his hand on the gun in his trousers' pocket. Yes indeed those were lively times! Stratton himself used to laugh at Doyle and Burns; he was absolutely fearless. The affair ended in a long-drawn litigation and in Burns getting the control, which he afterward lost to Howbert and some of the others.

Why did you leave the Portland?

On account of these rows and bickerings. My engagement was only for a year, so that when the year elapsed, I went to the Yukon. That was in 1898, the year of the big stampede. Stratton was interested with me in the venture. I took six assistants with me, and sent them ahead over the ice to Dawson, following them myself in the spring of '99 on the old steamer *Leelannaw*. She was torpedoed recently by the Germans.

That must have been an exciting episode.

It was; a big mob of people was going to the diggings. Most of them did not know what they were going to do. I went by water to St. Michael, and up the Yukon to Dawson, so that I missed the horrors of the White Pass. Arriving at Dawson, I saw a great crowd of people camped on the river, a town was being built rapidly, warehouses were going up—the usual excitement of a mining camp—but I did not stay long in Dawson. I went out on the creeks, and stayed there for nearly a month, tramping around and investigating. Finally I bought some claims on Bonanza creek, between Fox and Monte Cristo gulches, and extending down to Bonanza. I also started a survey up the creeks, with the idea of building a railroad. I sent men among the diggers to check off the amount of freight that was coming in, to find out what it was costing. The profit to be made on 60-days freight would have paid the cost of a narrow-gauge railroad. I took the plan to Ottawa, but I could not get a charter without giving the greater part of it away to political grafters. It was two years before we got the charter, and by that time the interest that was left to Stratton and myself was only 36%, 64% having gone to the Ottawa lobbyists. I regret to have to say that

at that time Canadian politics was thoroughly rotten.

Did you return to Dawson?

From Ottawa, yes. I went in over the ice from Skagway with a dog-team. That was in March 1899. At that time Dawson had become more settled; they had built better trails up the creeks; the claims were being worked systematically and with intense energy. I worked my claims for two years, and then sold them at a profit of \$65,000, of which Stratton was entitled to half, but he refused to take any of it, so that I got all of it, thanks to his generosity. I sold because I had decided that I did not want to live there. The winters were too cold and the work required too much supervision. Incidentally, I may say that I was one of the first to recognize the usefulness of steam-thawing and to use it. After selling my claims, I came out to Seattle and bought all the small boilers I could find in Seattle, Tacoma, Portland, and Vancouver. Altogether I got about 35 small boilers, some small hoists, thawing-tools, pipe, and so forth, and shipped them into Dawson.

You made money over that?

Yes, I cleared about \$50,000 out of that deal.

Speaking of thawing, do you refer to the use of steam-points?

Yes. At first the people on the creeks used to take empty gas-tanks, the kind used for charging soda-water. They were about 6 in. in diameter inside, and about 5 ft. long, standing a pressure of probably 1000 lb. per square inch. Then they drilled dozens of little holes about $\frac{3}{4}$ in. all around them, cut off short pieces of pipe, about a foot long, welded one end, cut a thread on the other—so that they played the part of tubes in a tubular boiler—and screwed those short pieces into the boiler, then admitted feed-water near the bottom and drew steam at the top. The tank or miniature boiler was set on end, enclosed in stones cemented in mud, and a fire was built at the bottom. The steam thus generated went to the 'points,' which were steel pipes with a solid piece of steel welded at the front end so that they could be driven into the ground like drills.

What did you do next?

I went to the Mariposa grant for Wernher, Beit & Co. I had become acquainted with Hamilton Smith during a visit that he made to Cripple Creek to inspect the Independence mine. When the British financial firm purchased the Mariposa grant from the former owners, the trustees of the Alvinza Hayward and J. P. Jones estates, Hamilton Smith asked Capt. Thomas Mein to look me up, and the latter then offered me the position of manager of the grant, which included a group of five mines that had been worked in the early days by John C. Fremont.

Yes, I happen to know about that, because my grandfather, James Rickard, came to California in 1850 to examine the Mariposa grant in behalf of the firm of John Taylor & Sons. The grant had been placed in London by General Fremont, known in romantic

THE OUTCROP OF THE INDEPENDENCE

history as the 'Pathfinder.' My grandfather brought a sectional stamp-mill from Cornwall, and made a thorough test, the result of which was an adverse report. Of course, at that time, the cost of mining was high, and a low-grade mine that might be highly profitable today would not be worth looking at 66 years ago.

That is true, but we also found the ore left by the old-timers very low-grade. After pumping the principal workings, we found no ore that would pay, even with present methods of mining and milling. The best ore left in the Princeton—the principal workings—assayed only \$2 per ton. Our predecessors had worked out the ore that was profitable to them, and a good deal that left no margin, but after extensive development work we found good ore below the old workings.

Do you think that there is any chance of successful mining on the Mariposa estate?

Yes. I do. We sank below the lean zone, and found good ore between the 600-ft. point, where the old company stopped, and the 1000-ft. level of the Princeton. We had long and wide stopes of good ore.

How good?

To the best of my recollection it ran from \$4.50 to \$5 per ton. I might add that there was also in one mine, the Mariposa, some profitable ore that the old company had left because it was so hard that it could not be stoped profitably without ma-

THE INDEPENDENCE AND PORTLAND MINES, CRIPPLE CREEK.

chine-drills, which were not in use at the time mentioned.

How long were you there?

I was on the Mariposa grant from 1899 to 1901, and I left owing to the offer of the management of the Le Roi mine and the Northport smelter. The offer came to me through R. J. Frecheville. At that time Mr. Frecheville was examining the mine, and the Le Roi Mining Co. had been the victim of Whitaker Wright's operations, being indebted to the Bank of Montreal for some half-million dollars. Whereupon the bank had insisted on an examination by Mr. Frecheville, and on a re-organization of the management; so I went there in November 1901.

You found things in bad shape?

Yes. The Northport smelter had been badly handled. There was 80,000 tons of copper ore in the roasting-yard that would barely pay the cost of smelting. This had been done apparently to boost the stock. Whitaker Wright left things in a sad mess.

You would not condemn the British management of mines wholesale?

Certainly not. I have seen as many mines managed conspicuously well as conspicuously badly by English companies, and, after all, the local management at Rossland was not British. However, I do recognize the difficulty of managing a mine in the United States when the board of directors sits in London, and is wholly unfamiliar with the local conditions. The only remedy is for the directors to place authority in the hands of a competent resident manager, and they must give him a pretty free hand, otherwise he is severely handicapped by the delay in getting permission to do things, and by the uncertainty as to which individual is in control at the other end. Business that requires instant decision may have to wait for weeks.

What sort of an experience did you have at Rossland?

There was a strike on at both the mine and the smelter when I arrived there, making it rather difficult for the first few months, but at the end of a year we had paid off nearly all the debt to the Bank of Montreal, and the affairs of the company improved daily. At the end of two years, when I left there, we had about \$460,000 in the treasury.

What happened then?

Then I resigned, as I wished to return to the United States.

What next?

I joined F. W. Bradley, here in San Francisco, in the work of examining and managing mines, and we continued to do that for several years. Between 1903 and 1905 Mark L. Requa joined Bradley and myself, and we did a general consulting business. At that time Requa had an option on what is now the Ruth portion of the Nevada Consolidated. Bradley and I joined him in the enterprise. All of us spent a good deal of time at Ely, and made the necessary tests, by drilling and milling, to determine the value of the property. Requa was in di-

rect charge of this work, which led to the organization of a company, by James Phillips and W. Hinkle Smith, called the White Pine Copper Co. That was in November 1904. Out of this and the Boston & Nevada Copper Co. grew the Nevada Consolidated, which has proved such a splendid property.

You made some money out of that?

Yes, we all made money, but we had to surrender control, owing to the fact that our Eastern friends insisted on selling to the Guggenheims. Still, we did very well.

Are you still interested in the Nevada Consolidated?

No. We have gone into a lot of other things since.

What was your next venture?

I went back to the Le Roi in 1905, with R. W. Brock, of the Dominion Geological Survey, for the purpose of appraising practically all the large mines in the Rossland district, including the Centre Star, Le Roi, War Eagle, also the St. Eugene at Moyie, and the Trail smelter, for the purpose of an amalgamation planned by Sir Henry Tyler, who was chairman of the Le Roi company, but this amalgamation fell through, owing to the hostility of A. J. Macmillan, who at that time represented the minority shareholders and subsequently became managing director.

When did you become manager of the Goldfield Consolidated?

In 1907. The management was offered to me on the initiative of William H. Crocker, in association with Senator Nixon, the partner of George Wingfield in his mining ventures.

You had a lively time while at Goldfield?

Yes; four days after I arrived there was a strike called, and the whole property shut-down for a time. I was glad of the shut-down, because it stopped the stealing of ore. Up to that time the Goldfield Consolidated had only a small mill and was shipping a great deal of ore to Salt Lake, paying high railroad and shipping rates, as well as excessive reduction charges. The strike gave us time to build a mill of our own, which we did, commencing in January 1908, and finishing in December of the same year. This was a 100-stamp mill, capable of treating about 600 tons a day; afterward a Chilean mill addition was put on, and the plant was raised to 1000 tons per day capacity.

Mr. Mackenzie, you have been in charge of a great many mines, and have come in close contact with the working miner. What do you consider the main cause of trouble between the companies and their men?

The walking delegates, and the lack of co-operation between the management and the better class of their men. As a matter of fact, while I have been through three strikes, I have prevented a great many strikes by getting the better class of workmen before me and talking in a friendly manner with them, making an effort to show them that the company or its management had no desire to take advantage of them, but, on the contrary, was trying to be fair to them. Usually this kind of argu-

THE MOTHER LODGE REGION IN MARIPOSA COUNTY, CALIFORNIA.

ment, especially when really true, would always be listened to with respect.

Do you recognize the right of unions to act together? In other words, for the local union to join with unions in other districts in making a demand?

I recognize their right to do so, but I do not believe it is always the best policy for either the mining companies or the unions to join large labor organizations that have nothing in common with the particular work or other local problems, but I do recognize the right of combination, and of collective bargaining. We all do it.

I take it, however, that you do not regard the Western Federation as a union within the law?

Certainly not. I do not recognize the Western Federation as a good friend of the Western miner. I do not approve of their methods of gaining their points. I do not believe that they have helped to further the just demands of our Western men. In the early days of Nevada, the miners' unions of Eureka, Virginia City, and White Pine were organized as locals, and as individual unions they gained more advantages from the mining companies than the Western Federation ever gained afterward by their methods of intimidation.

How long were you at Goldfield?

As manager I was there a little over two years. For

two years longer I was consulting engineer and director, that is, until the early part of 1912.

You returned to consulting practice in San Francisco?

No. All three of us—Bradley, Requa, and myself—were so absorbed in enterprises in which we had placed our own money that we did not look for clients. However, my work at the Alaska Juneau has been of a consultative kind.

When did you get into that?

Bradley had been connected with the Alaska Juneau for many years, and in 1910 Requa and I joined Bradley in driving the new adit and other work, for which we received a block of shares out of the treasury of the company. Subsequently we, together with Mr. Crocker, purchased the Wernher-Beit interest in the Juneau property, so that we obtained control.

You made a report on the mine in 1915, I believe?

Mr. Bradley and I made a joint report, estimating 80 to 100 million tons of ore to be mined and milled. Given sufficient money to develop and equip the property we estimated a profit of \$1,400,000 per annum as reasonably assured. On this report we sold 400,000 shares of the treasury stock, netting the company \$8 per share, a large block being taken by B. N. Baruch and associates.

Mr. Mackenzie, I am going to ask you a question that

AJOIA DURING THE TUNGSTEN BOOM.

may be difficult to answer. To what extent do you think these enormous bodies of low-grade gold ore can be sampled?

My personal opinion is that the usual methods of sampling are of no use in such orebodies. You have to carry out the test on a milling scale, that is, crush thousands of tons and take samples right across the vein, quite similar to a moil cut, and, in addition you have to take it at different levels on the orebody. We milled 50,000 tons from across the orebody lying north of the Silver Bow fault, and we based our calculations on the value of the ore north and west of Silver Bow on that mill-run. On the south-east side of the Silver Bow fault, adjoining the Alaska Gastineau property, we based our calculations on about 480,000 tons of ore that had been mined and milled during the life of the Alaska Juneau, prior to and after our acquiring control.

Can you find out the number of raisins in the cake without eating all of the cake?

No. Absolutely no. Therefore, even sampling on this scale is only an approximation, but it's as close as one can afford to go.

Of course. If you take more out, you may as well take all out, and the sampling becomes an exploitation on a large scale, and ceases to be sampling.

We are compelled to take some risks on sampling and estimating orebodies similar to those on Douglas Island and in the Alaska Gold and Juneau mines. Our calculations are based on estimates that may vary considerably when we come to take the ore out.

You have faith in the outcome of the big operations at Juneau?

I have. I believe the Alaska Juneau will earn the dividends that Mr. Bradley and I predicted, namely, \$1,400,000 per year.

Have you formed any opinion about the prospects of your neighbor, the Alaska Gold Mines?

I have not been through the Alaska Gold mines for over two years. At the time of my last visit, it looked to me that they would make good on their estimates of producing a net profit of 75c. per ton. Since that time I understand that they have had some difficulty due to the hanging wall of the vein caving and mixing with the ore, resulting in reduction of grade. While they may not be able to earn 75c. per ton net profit, I believe they will be successful in earning a substantial profit—a profit that will justify them in their original investment on the property.

By the way, Mr. Mackenzie, you are one of those that profited from the rise in tungsten, I believe.

Yes, I have an interest in the Atolia mine, together with my friends, Mark Requa, Fred Bradley, Baruch Stent, and Voorhies. While the price of tungsten was soaring, we made some nice dividends.

Are the technical operations interesting?

The Atolia ore is scheelite associated with quartz in a fractured zone through the granite. The vein is faulted

and twisted so much that it is very difficult to follow it. The interesting thing about tungsten is that none of the producers are using the soluble treatment of it. The Germans have been doing it for years, and we are planning a soluble-treatment plant and refinery, and have decided to erect one at Atolia. At the present time we mine the ore and transport it to a mill that will treat about 65 tons per day, crushing and concentrating in a manner similar to lead and copper practice, and making a concentrate containing from 50 to 75% of scheelite. We ship it to the Eastern markets, where it is bought by the tool-steel makers and the electrical-equipment companies.

So the Atolia is a war-baby?

The price of tungsten went up from \$7 per unit at the outbreak of the War to \$75. The price is now between \$15 and \$18 per unit and we anticipate a still further reduction when peace is declared.

Do you expect to operate profitably when peace is declared?

We do, because we believe that we can operate the Atolia mine and produce tungsten as cheaply as any other mine in the world. If the price goes to \$10, we shall be able to make a fair profit, and we have every reason to believe that it will not go below \$10, because a great many new uses have been found for tungsten during the period of the War, and the known sources of supply are limited.

From what episode in your career do you derive the most satisfaction?

There are several episodes that I believe gave me equal satisfaction. Developing the bonanza orebodies in the Independence and Portland mines, the pulling of the Le Roi company out of debt and putting it on a sound financial basis, the opening up and developing of the tremendously rich ore deposits of the Goldfield Consolidated group of mines, together with the building and putting into successful operation of the Goldfield Consolidated mill within a period of eleven months gave me a great deal of pleasure and satisfaction.

Do you consider mining a good career for the young American of today?

I believe there is a good field for trained underground superintendents or foremen. Trained men are difficult to find and are always in demand. In order to fit himself to be an underground foreman, a young man must spend several years as a miner, timber-man, and shift-boss, and if he has the physique together with the courage and patience to gain the necessary experience, I think his services will always be in demand at a good salary.

Do you believe in the adoption of concentration in lieu of amalgamation and cyanidation in the treatment of the low-grade ore at Juneau?

After several months experimenting with a 50-stamp mill at Juneau, with and without amalgamation, we demonstrated that the tailing-loss was no greater using concentration alone than when using amalgamating

plates prior to concentration, while the cost was slightly less. The average ore in the Juneau gold belt is too low in value to bear the expense of cyanidation.

What methods of mining do you consider best for wide bodies of ore separated by considerable thickness of poor ground?

No fixed method can apply to all, as so much depends on the nature and value of the ore deposit and whether the walls, or boundaries, will stand, or are soft and likely to cave. As a rule the poor bands can be left in place or used for filling. Where ore is of good grade, square sets and filling will give the largest percentage of ore-recovery and the best control of stoping. Where an orebody is large and lean, the loss of ore is not so vital and some system of caving or shrinkage may be the most economical.

What are your views concerning the proposed changes in the mining law? I refer more particularly to the abolition of the extra-lateral right and the requirement of discovery before location?

Our present mining laws have been the cause of expensive litigation in the past and appear to me to be more beneficial to the legal profession than to the owners of mines. Senator Smoot's bill withdrawing the extra-lateral right from future locations is a step in the right direction, but locations already made under the extra-lateral law should be left undisturbed as most of them have already settled their differences in Court. In British Columbia claims are staked 1500 ft. square with no extra-lateral rights and the boundary monuments placed by competent men appointed by the Government. Rossland furnished a good example of the operation of both the extra-lateral law and the square location without that right. The first locations made in this district had extra-lateral rights which were the cause of expensive litigation, and expert lawyers and geologists from the United States were imported to try some of the cases. The law was repealed and locations made without extra-lateral rights, the result being that there has been no serious or costly mining litigation over the later locations.

How about the requirement of discovery?

The question of making a discovery before location has many sides to it. Where outcrops carrying ore exist, the law works no hardship on a prospector, but the porphyry copper districts would have experienced many difficulties if discovery before locations had been strictly enforced. At Ely, Nevada, the operating companies purchased from the original locators many claims that had been held for several years without any real discovery. Some of these claims I feel sure never have had an exposure of ore on the surface, but today all are patented. Where no actual outcrop exists and the geological features indicate the possibility of valuable orebodies underneath, the prospector or mining company should be given a prior right to prospect without a discovery and be allowed ample time to sink shafts and demonstrate the value of the territory located.

What do you think of Albert Burch's suggestion to give instruction in mining to American young men at the mines and at the instance of the operating companies?

I fully approve of Mr. Burch's suggested plan of giving free instruction in mining to worthy young men at the expense of large operating companies. Like Mr. Burch, I have seen the young Americans and the strong sturdy men from Cornwall, Ireland, Scotland, Nova Scotia, and Canada gradually disappear from our Western mining camps. I think it is safe to say that in the year 1878 fully 95% of the miners in Nevada came from these countries, and a more intelligent and capable lot of men could not be found anywhere. Many of these men were competent to fill the positions of timber-men, shift-bosses, or foremen. Today the young Americans do not care to spend several years at hard work underground competing with foreigners, many of whom cannot speak English, but I believe that if the companies engaged in mining would furnish schools and teachers that would educate and fit the beginners for the better-paying positions and, when deserving, give the men so trained a preference, it would induce the young men to stick to their jobs and thereby gain the necessary experience to fit them for the positions they knew would be within their reach, provided they proved worthy.

SCHEELITE. The occurrence of tungsten ore in the Coeur d'Alene region, so far as known, is wholly confined to slate. The ore (scheelite) is found in quartz veins associated with gold, silver, pyrite, chalcopyrite, sphalerite, galena, magnetite, and siderite. The vein material varies from white quartz carrying gold, with but little sulphide mineral, to practically solid sulphide, usually rich in gold, with a small amount of quartz, or none at all. The gold is frequently found in pockets, from little bunches to some worth several thousand dollars. Small shoots of ore not infrequently run over \$500 per ton in gold and there are large veins that carry from \$1 to \$7 per ton in gold. Scheelite is found in many places in the region, but only in the slate and argillite. It occurs in bunches, lenses, stringers, and in disseminated grains, and it is known to persist as deep as the deepest workings, 900 ft. below the surface. For the most part the tungsten is found in veins that intersect the slaty rocks in strike and dip and in planes nearly normal to the fissure-veins of the district. In many instances they are traceable for a long distance. These tungsten-bearing veins are found separated by a distance of 200 ft. or less, though the distance is by no means regular. Little mining has been done in the slate area of the Coeur d'Alene in recent years, though it was the field of the first mining activity, in 1883 and 1884.

SULPHURIC ACID to the amount of 100 tons is being made daily at the Garfield smelter from the fume. This formerly went to waste through the stack.

NATURAL GAS to the extent of 628,578,842,000 cu. ft. was used in the industries in the United States in 1915.

Notes on the Metallurgy of Copper

By David H. Browne

*Some of the best ideas of today are really old ideas adapted to modern conditions. Take the charging of blast-furnaces for example. If you analyze the situation there is a lot of food for thought in the subject. A blast-furnace runs continuously, discharging an uninterrupted stream of matte and slag at the spout. Follow what goes on inside the blast-furnace and we find the continuity still existent. Here is a cold charge, continuously descending under the force of gravity, continuously pushing an unfused mass downward into a smelting zone in which it melts into matte and slag. Climb on up the blast-furnace a bit. Is this cold mass continuously replenished? Not so that you could notice it. The charge comes in intermittently. The top of the charge is black just after the charge-cars have been dumped. Watch this charge as it sinks and you notice that as it goes down it gets hotter and hotter, at times and in places coming to a red heat before the next charge follows. This spells heat-losses, more fuel than is needed, and higher smelting costs. Theoretically, charging should be as continuous as the slag-flow, and an even temperature should be maintained at the furnace-top. We have attained this condition in modern reverberatories and by continuous charging of ore and fuel the humps and hollows in the temperature-chart have been ironed out into an unbroken line, which means economical use of the available heat. It would be highly desirable if the same condition could be reached or even approximated in our blast-furnaces.

But we have to consider not only the time when a charge enters the blast-furnaces, but the way in which it is spread. The charge is not uniform. We have ore, both coarse and fine; coke, usually coarse; and flux which may be of any size. Each of these is required at a certain position, and it is this location of the particles that forms the puzzle of blast-furnace charging. In the first place we must provide a way in which the products of combustion can escape readily and under an even pressure. For this reason any stratification of the charge must be vertical and not horizontal. The descending stalactite of unfused charge must have a uniform cross-section at various heights. Hence any arrangement that produces layers—a layer of fine and a layer of coarse ore, for example—is barred by the nature of the case; while any arrangement that tends to build up the various ingredients in vertical column, say, the coarse ore at the centre and the fine ore at the sides, is permissible. Coke—where is it to go? Consider that coke has only one function in the metallurgy of the copper blast-furnace; that is to furnish heat. There is no reduction to be accomplished as in lead and iron smelting. The only con-

sideration is where this heat is best applied. This naturally is along the jacket-walls, to prevent scabs and crusts of unsmelted charge narrowing in the furnace. Coke is only a heat-producer. Some of these days cupolas will be run by powdered coal. In fact, it has been done, the day before yesterday. "Where? How? By whom?" you ask. Wild horses could not drag it from me. Wait a while and you will know all about it. But to get back to the charge-floor. Flux is the next thing. Evidently the flux should go where it is needed—a particle of flux alongside of each particle of ore that needs flux. Hence bedding or thorough mixing of ore and flux outside the furnace is the only common-sense solution of the flux question. So we have the problem to get the ore and flux mixed, to get the coarse ore with its coarse flux along the middle, fine ore and its flux along the outside, and coke as a pad between the fine ore and the furnace-jacket. Add to this the desirability of doing it all continuously and you have the idea.

There was only one charging-machine ever built along these logical lines and that was designed ten years ago by W. H. Freeland, who had more real metallurgical sense than any man I know. This is all ancient history now, but you will find that Freeland's ideas are still alive and every now and then someone makes use of them. The furnaces at Isabella were of the open-top variety; that is to say, the gases were carried to the stack by a lateral take-off below the charging-floor. Freeland had experienced the usual troubles of hand-feeding and to correct these devised his charging-apron, which is generally acknowledged to be the neatest charging-device known to the profession. This machine is rather difficult to describe, but as cuts cost money and the C. M. I. has none to spare, we must see what can be done with the English language.

You know the old fashioned roller-towel that hung behind the kitchen-door. Imagine one of these as wide as the furnace top and as long on the double as the length of the furnace. It is made of steel slats, which are carried on rollers that support it every few feet. These rollers are carried on a horizontal steel frame provided with wheels and running on a track over the furnace. These slats are turned up at the outer edge, so that the whole arrangement forms a sort of pan, with sides formed of these overlapping turned-up edges. Over this belt are two motors. One of these motors propels the machine along the rails, the other turns the rollers and thus makes the belt move. This apparatus stands under the charge-bins, which are very close to the furnace. It passes first under a double row of coke-bins. These pour a double line of coke along this belt at its outer edges, leaving the centre of the belt bare. Passing now under

*From the Bulletin of the Canadian Mining Institute.

the flux-bins a layer of flux is spread along the centre of the belt; over this in turn the ore-bins spread the ore. The machine carrying its charge moves forward toward the furnace. The top of the furnace is covered by a water-cooled lid, resting on wheels, on the track on which the charge-car approaches. The charge-car has a bumper in front. This bumper meets the movable furnace-cover and pushes it along ahead of the charge-car, leaving a slot the width of the furnace through which the charge-feeder can look down into this furnace. If the top of the furnace is level and even, the feeder starts the belt moving, spilling the charge off the end of the belt. The coke falls against the walls because it is piled on the edge of the belt. The mixed ore and flux falls in the middle of the furnace because it was spread down the centre line of the belt. Thus by the time the charge-car has got to the far end of the furnace it has spilled the charge evenly all the way. Reversing the motor the charge-car slides back, pulling the lid over the furnace as it recedes. This is certainly neat in conception and smooth in operation. If the furnace is not working regularly, more or less of the charge can be placed at any spot desired.[†]

All this, I said, is ancient history. I cite it just to show the persistence of ideas.

At the Granby smelter the charge-cars were hopper-bottom with side-discharge. Three of these cars formed a train the length of the furnace. At the top of each car, axles supported a supplementary set of four wheels. These cars were run directly into the end-doors of the furnace where the upper wheels traveled on rails fastened on the inner side of the walls. When in place the contents were discharged from outside by an operating handle which released the side-gates. Here we have the same idea that Freeland had, of dropping a charge without altering its previous arrangement and adapting this to furnaces that rise above the charge-floor. As a rule, however, almost all the copper-furnaces have been fed from the outside by cars that roll or dump or slide the charge in and thus upset any arrangement. Whether this is simply conservatism or whether it is a necessity imposed by other conditions is a moot question.

The latest development is the device in use at the Calumet & Arizona plant at Douglas.[‡] The furnaces are 40 ft. long by 4 ft. wide at the tuyeres. The charge-cars run at right angles to the furnace instead of parallel to it, as is customary. The ore-bins are in the furnace-building parallel to the furnace and fed by overhead belt-conveyors, thus making a very short haul for the cars. In fact, the coke-bins are only 7 ft. and the ore-bins 15 ft. from the furnace-door. The charge-cars are 20 ft. long, and four cars, two on each side, shuttle back and forth between bins and furnace. The charge-car has four compartments and the bins overhead have a gate corresponding to each compartment, so that the amount of charge for any part of the furnace can be regulated. The cars have a sloping bottom that is continued down-

ward into an apron, which, in turn, when moved up to the furnace, is in line with the feeding-aprons above the water-jacket.

This again is neat, particularly the way in which the time element has been taken care of and the haul shortened. It does not, however, take into consideration, as did Freeland's scheme, the accurate placing of coke along the walls and of ore in the centre. Ore, particularly coarse ore, will shoot ahead of the rest of the charge, and fall near the centre if the charge in the furnace is high, or near the opposite wall if it is low, while fine ore will fall more closely off the edge of the apron. It may be that the designers of the Calumet & Arizona furnace had this in mind and make use thereof in the placing of the charge.

When all is said and done, however, Freeland's scheme is the only one which takes into consideration three things, and which does these three accurately. It has the short haul. It places the coke outside next the jackets. It feeds as much or as little as any particular part of the furnace desires. The disadvantage, of course, is that it is adapted only to furnaces that have an unobstructed charging-floor, and that is why it has not been generally adopted. What we really need is some device that will reduce the haul to zero, and that will feed the furnace continuously with a charge in which the ore and flux properly mixed are placed in the centre while the coke is fed mainly against the jackets.

THE Minshall gas well, in the Macksburg field of Ohio, was allowed to discharge its gas into the air for ten years. In 1885, when placed partly under control, it had a measured volume of 4,500,000 cu. ft. of gas daily, under a pressure of 425 pounds. It is estimated that the total waste of gas from this single well was not less than 15,000,000,000 cubic feet, equal to 750,000 tons of good coal. A gas well in Kentucky wasted in like manner \$3,000,000 worth of fuel. A well in Buena Vista field, Kern county, California, wasted 55,000,000 cu. ft. of gas daily for three months, when it was placed under control. The waste from this one well alone, figured at 25 cents per 1000 cu. ft., was \$1,250,000. In the Cushing field of Oklahoma, the waste of gas was larger, perhaps, than in any other field, and at times exceeded 500,000,000 cu. ft. daily. No fires nor open lights were permitted and automobiles were not allowed among the wells for fear of ignition of the gas which filled the atmosphere. The total waste from that field was estimated at 250,000,000,000 cu. ft., equal in fuel value to 12,500,000 tons of coal.

VESSELS passing through the Panama Canal require about 11 hr. 40 min., as determined by the average time taken by 158 ships passing through the Canal in October. The greatest length of time for any vessel was a little over 16 hours, but some passed through in less than 8 hours.

GOLD OUTPUT of the Rand in October was valued at \$16,370,000.

Geological Occurrence of Manganese

By J. J. Runner

*Of the elements composing the earth's crust, manganese is estimated to form about 0.08%. It is commonly associated with iron which is about 55 times as abundant. Like iron its chief original source is in the basic igneous rocks where it occurs chiefly in silicates, while iron is found in oxides and sulphides as well as in silicates. Since the sulphides of iron particularly favor the basic-igneous rocks, the acid-igneous rocks have a relatively higher manganese-content. Of less importance may be mentioned the association of barium with manganese in many ores.

Of minerals containing manganese, over 110 distinct species have been recognized and described, relatively few of which are important as ores. The ore-minerals are chiefly of secondary origin, derived from the primary silicates after chemical disintegration, solution, and precipitation mostly in the form of oxides. Among the more important ore minerals are the following: psilomelane, MnO_2 with MnO , BaO , or K_2O ; pyrolusite, MnO_2 ; mangafite, $\text{Mn}_2\text{O}_3 \cdot \text{H}_2\text{O}$; braunite, $3\text{Mn}_2\text{O}_3 \cdot \text{MnSiO}_3$; hausmannite, Mn_3O_4 ; wad, an impure mixture of manganese oxides; rhodochrosite, MnCO_3 ; and rhodonite, MnSiO_3 .

On a commercial basis, ores important because of their manganese-content have been classified in the United States as (1) manganese ores; (2) manganiferous-iron ores; (3) manganiferous-silver ores; (4) manganiferous-zinc ores. The first of these is mined alone for its manganese-content. The second class may be mined for iron alone, or if the manganese-content is high enough, may be used in the production of spiegeleisen, or ferro-manganese. The iron is commonly in the form of limonite or hematite, while the manganese occurs chiefly as psilomelane or pyrolusite. The third class usually contains iron minerals associated with the manganese, and some lead with the silver. They are valuable as (1) sources of lead and silver, the iron and manganese acting as fluxes in smelting; (2) sources of manganese or iron; (3) fluxes in smelting of other lead or silver ores.

From a geological standpoint it is better to classify ores according to their mode of origin, and they shall be discussed here upon that basis. The important deposits of manganese of the world may be classified as (1) residual products of rock weathering and decay; (2) bedded deposits as a result of chemical precipitation in surface waters; (3) lodes; (4) metasomatic deposits; (5) contact deposits. By far the greater part of the world's manganese production is derived from the types illustrated by No. 1 and 2.

Rocks containing manganese minerals in quantities too small to make them of commercial value, may, by proc-

esses of weathering and the attendant solution and removal of soluble materials, leave residuals of insoluble manganese compounds with oxides of iron, silica, and clay, that form valuable orebodies. In such ores manganese is commonly accompanied by barium. To this group probably belong most of the manganese deposits of India. They have been responsible for the development of a flourishing industry and have produced several million tons of ore, in some years leading the world in production. One type consists of ores that have been derived from rocks containing manganese-bearing silicates, by decomposition and replacement forming large masses of psilomelane, pyrolusite and braunite. In part the ores are of rhodonite and manganese garnet in crystalline schists. The ore-beds are in places 100 ft. thick, and several have been followed for two miles along the strike. Much of the ore contains 50 to 55% manganese. Manganese-bearing residual clays furnish a source of a small part of the ores of India.

In Brazil valuable manganese deposits occur chiefly in two districts in southern Minas Geraes. In the Miguel-Burnier district manganese ores occur in an ancient sedimentary rock, the same that contains the great Brazilian iron-ore deposits. They are probably to be regarded as syngenetic deposits, in the same sense as the iron ores. Of greater importance as a producer is the Queluz district. The ores occur as surface alterations of a rock containing rhodonite, manganese garnet, manganese olivine, and rhodochrosite. The original garnet-containing rock is considered by some to be an igneous rock, while others look upon it as a product of contact metamorphism, of lenses of manganese carbonate in the schist. The region is one of granite, gneiss, and schist.

In the Huelva district of south-western Spain, occur manganese ores interbedded with a clay slate, and associated with effusive diabase. The ore-lenses consist of banded, compact, or of irregular, coarse carbonate and silicate-manganese minerals, with jasper and hornstone. The lenses are generally less than 500 ft. long, and have an average depth of about 100 ft., and in thickness range from a few feet up to 150 ft. or more. The primary minerals are largely rhodochrosite and rhodonite which in the upper parts have been altered to oxides, chiefly psilomelane. The early production was from the oxidized ores, but later the primary ores began to be mined and in some years, 1877 to 1900, the output ran over 100,000 tons of the latter. The precise mode of origin of the primary ores is in doubt, some regarding them as products of sedimentation, others as a result of metamorphism and cavity filling. The altered surface ores at least are a product of residual weathering. The pro-

*Abstract from 'Manganese Number' of the *Pahasapa Quarterly*, South Dakota School of Mines, Rapid City, S. D.

duction from this district has been large but now has ceased nearly altogether.

In Bosnia, occurs a deposit of hard manganese ore-nodules, lenses and beds of psilomelane, rich in barite, occurring in siliceous radiolarite. The original deposit is looked upon as analogous to the concentration of manganese nodules at present forming in the deep sea clays of the ocean.

In southern Bukowina, manganese occurs in the form of pyrolusite, wad, and botryoidal psilomelane, as a weathered product of manganese silicates and carbonate. Ores of this type are also found in Carniola and Moravia. Altogether these districts have produced many thousand tons of ore.

Valuable deposits of manganese have been mined in Cuba on the north flanks of the Sierra Maestra. The ores occur in a disintegrated green glauconitic sandstone. Above this sandstone layer is a bed of foraminiferal limestone. It is probable that the manganese has been concentrated from beds of marine origin.

Most of the manganese ore produced in the United States has been from Virginia, Georgia, Arkansas and California. The Virginian deposits are found chiefly in the James River area, in the Piedmont region, and the Appalachian Valley region. The chief producing region in Georgia has been the Cartersville area in the Appalachian mountains. In both States the manganese occurs chiefly as nodules, grains or lumps, irregularly scattered through residual clay, and in cavities in the underlying rock. The manganese is believed to have been leached from pre-Cambrian crystalline rocks, deposited in Paleozoic sediments, then concentrated by the process of rock weathering and decay. In Arkansas manganese ore is found associated with limestone, in residual pockets, in clay derived by leaching. The Californian deposits are the result of secondary concentration of manganese from a bed of jasper.

Some of the iron ores of the Lake Superior district have furnished important sources of manganese. Little manganese has been mined separately, but some of the ores of iron are rich enough in manganese to be valuable as sources of manganese pig-iron which has special uses. Since these ores have been concentrated largely as a result of leaching by ground waters, they may properly be mentioned here.

The Leadville, Colorado, deposits, famous for their silver, lead and zinc, are generally regarded as replacement deposits in limestone. The primary ores contain about 1% manganese with some iron which in the oxidized zone gives rise to ores containing 15 to 25% manganese oxide and 20 to 30% iron oxide. These surface ores are of three grades, (1) valuable for lead and silver, the manganese and iron acting as fluxes in smelting; (2) as sources of manganese and iron for spiegeleisen; (3) fluxes in the smelting of other ores, the lead and silver being recovered. Similar ores are produced at Neihart and Castle, Montana.

Among the more important deposits of manganese that seem to have been formed as precipitates in surface waters are the following described occurrences:

In the province of Kutais, Trans-Caucasia, occurs one of the world's greatest deposits of manganese. The manganese-bearing bed lies at the base of Lower Eocene sandstone near the surface of a plateau. The deposit is on the average about 7 ft. in thickness, within which are 5 to 12 manganiferous layers of varying thickness, alternating with beds of marl, some of which are also impregnated with ore. The ore consists of oolitic pyrolusite in a matrix or fine-grained, earthy manganese ore. The deposits are said to extend over an area of some 22 square miles. They contain from 40 to 50% manganese. The production from the area has been large, totaling 600,000 tons in some years.

The deposits near Nikopol, south Russia, are similar to those of the Kutais district. The ores are in beds of sandy clay 3½ ft. thick with nodules of pyrolusite and psilomelane, having a concentric or cellular structure. The ores lie only a few feet above crystalline rock from which they are believed to have been derived.

To this class probably belong the deposits of the Coquimbo, and Carrizal districts in Chile, which up to 1900 had furnished several hundred thousand tons of ore, but have produced little since. The deposits form fairly extensive beds in Jurassic-Cretaceous sandstones, slates, limestones and gypsum beds, resting upon igneous rock. The ores are chiefly oxides and silicates with barite, calcite and quartz. The manganese-content averaged 50%.

Of geological interest, but of small economic importance, are the occurrences of manganese that have formed in open fissures or other cavities in rocks. The distribution of payable manganese lodes is limited to a few districts in Germany, France, and Japan.

Closely allied to the manganese lodes are the metasomatic manganese deposits, and like the lodes they are relatively of small economic importance. A number of the iron-manganese deposits of this type are of considerable local importance, such as those at Lindener Mark, Germany.

Of manganese deposits of the contact type those of Langban, Sweden, are best known. The ores occur in dolomite and contain large flat lenses of hematite, and lenticular and clump-like masses of hausmannite and braunite. A large part of them are iron ores, a part iron-manganese ores, and a much smaller portion manganese ores. The ores are particularly interesting for the great variety of minerals found with them.

At Franklin Furnace, New Jersey, occurs a valuable ore of zinc and manganese in pre-Cambrian crystalline limestone in contact with gneiss of igneous origin. The ore is in a layer 12 to 100 ft. thick of metamorphosed limestone occupying a pitching synclinal trough. The ore-mineral of manganese is chiefly franklinite, and is used principally in the production of spiegeleisen after the removal of the zinc by roasting.

MANGANESE mines of Cuba are producing over 5000 tons monthly, the ore running from 43 to 46% manganese. More extensive operations are said to be retarded by shortage of labor.

Geology of the Cedar Range

By G. R. Stevens

The Cedar range lies about half in Mineral county and half in Nye county, Nevada. It has an east-west direction with a length of 14 miles and a maximum width of six miles. It is typical of this arid region, rising abruptly out of the plains.

The topographical features are a rugged core with a maximum elevation of 8000 ft., rolling foot-hills scarred by an occasional bold fault-scarp, and flat valleys. The oldest formation exposed is limestone of early Paleozoic age, but as far as I know no characteristic fossils have been found. It lies non-conformably beneath limestone of the middle Mesozoic. The few fossils I found in this indicated Jurassic age. Both of these limestones have been domed and intruded by grano-diorite and the whole again intruded by dikes of andesite and rhyolite, the flanks being covered by thick flows of lava during Tertiary times. These flows were in turn raised and broken, both by faults and by dikes of biotite-andesite, and tilted along an east-west axis. These last intrusions form the backbone of the range east and west of the older basement rocks exposed in the central core.

Four flows are shown—the oldest a thick andesite. This, wherever observed, is a blue, close-grained, highly-silicified rock. The next is a thick flow of rhyolite breccia showing inclusions, much kaolinized and probably fragments of the older andesite. The abundant large phenocrysts of quartz are the most noticeable feature of this rhyolite. Overlying, and separated from this formation by a stratum of tuff, is a flow, not more than 100 ft. thick, of soft green chloritic andesite. The last member of the series is a close-grained rhyolite weathering with a greenish stain and having much the appearance of the underlying andesite near contact with it. This contact has a thin layer of tuff in it also.

These flows must have followed closely upon each other, as I did not observe any signs of erosion or deposits of laterite where I examined the contacts on the surface or in mine-workings. Above the flows, in the valleys and lower hills, are extensive lake-bed deposits of late Tertiary or early Quaternary age, consisting of chemically-precipitated lime, a variety of alkaline salts, beds of tuff, and several strata of conglomerate, these last being composed of fragments of all the rocks found in the range.

In the Tertiary flows faulting has been extensive, the dominant fault being a thrust on the southern edge of the range and parallel to it. This has brought the underlying grano-diorite in juxtaposition with the flows. The uplift here probably was the cause of the subsidence on the opposite side as shown in the series of nearly parallel normal faults on the northern slope. In the fissures formed by this series of faults nearly all of the most promising veins were formed. Some ore, however, is found on the contacts between the flows. I made a study of one that started in a fissure at right angles to

the bedding-planes of the flows, and turned off flatly on a nearly horizontal fault-plane, and in the lower workings occupied the contact between an andesite and a rhyolite flow. This contact showed the effect of movement and is undoubtedly the plane of some minor faulting. The veins have been disturbed by post-mineral faulting nearly parallel with the original fissures, and a series of faults at right angles to the original system. Vein formation was contemporaneous with this last faulting, as indicated in places by a little ore (not 'drag,' but deposited) in the fractures connecting the dislocated segments of a vein. Most of the ore is a replacement and enrichment of original calcite veins. In places considerable calcite is left, making lean spots.

The structural details of a large part of the range are obscured by the lake-bed deposits, the strata of which are flat and unbroken for miles, so that much of interest will remain unsolved until future mine workings give the geologist a chance to study them underground.

The Hornsilver Mine

In 1916 the Hornsilver mine, at Frisco, Utah, paid two dividends, aggregating \$40,000. The present owners of this famous old mine have now received a total of \$5,962,000. Last year the lessees built a large milling plant to treat the dumps. The mine is at present a producer of lead, silver, and zinc. It was discovered many years ago and a large amount of high-grade ore was shipped. The orebody gave evidence of pinching out and it was sold at a good price to R. C. Chambers, of Salt Lake, who began a vigorous campaign of development, and soon had discovered a second orebody below the first and later found a third. In 1811 the mine produced 8171 tons of base bullion, and in 1882 the output was increased to 16,002 tons. The mine produced at that time 47,232 tons of ore at a cost of \$4.44 per ton; smelting at Francklyn cost \$14.73, and refining at Chicago \$9.05. The ore carried 37.8% lead and 34.2 oz. silver per ton, the smelting loss being 9.71% of the lead and 2.10% of the silver. The average of the grade of bullion was about 93 oz. per ton. In 1882 the dividends amounted to \$1,200,000, the net receipts for lead being \$1,326,664, thus indicating that the silver paid for nearly the entire cost of mining, smelting, administration, and marketing.

In 1884 the mine produced about 15,000 tons of lead, but the orebodies were rapidly being exhausted and on April 1, 1885, the mine was shut-down and the property remained idle for many years.

Several years ago the mine was re-opened, and under the improved modern methods of mining and metallurgy it has again become an important and profitable property.

MICA amounting to 20 tons daily is produced as a by-product in treating 150 to 300 tons of cassiterite and wolfram ores at the Hill City Tungsten Production Co.'s mill in South Dakota.

Copper Producers of North and South America in 1916

The following figures have been collected by the *Boston News Bureau*, and include all the mines that produced over 1,000,000 lb. of copper during the past year. No account is taken of refinery production, only mine or smelter operations being considered. The yields in pounds were:

Chemical and Mineral Prices at New York

The following table gives wholesale prices in the second week of January, according to *Metallurgical and Chemical Engineering*:

Chemical and unit	Price	
Acid, acetic, 28%, 100 lb.....	\$3.25	\$3.75
Acid, hydrochloric, commercial, 18°, per lb..	0.015	0.0175
Acid, nitric, 36°, per lb.....	0.0475	0.05
Acid, sulphuric, 60°, per ton.....	20.00	21.00
Ammonia, 26°, per lb.....	0.055	0.0575
Barium sulphate, powder, per lb.....	0.04	0.045
Borax crystals, per lb.....	0.0775	0.08
Carbon bi-sulphide, per lb.....	0.055	0.06
Caustic potash, 88-92%, per lb.....	0.84	0.86
Caustic soda, 76%, per lb.....	0.0425	0.043
Copper sulphate, 99%, crystals, per lb.....	0.1225	0.125
Iodine, re-sublimed, per lb.....	4.00	4.25
Lead acetate, per lb.....	0.13	0.135
Litharge, domestic, per lb.....	0.0825	0.09
Manganese dioxide, per lb.....	0.66	0.70
Potassium carbonate, 80-85%, per lb.....	0.34	0.36
Potassium cyanide, 98-99%, per lb.....	2.35	2.50
Potassium nitrate, per lb.....	0.27	0.30
Potassium permanganate, per lb.....	2.65	3.00
Silver nitrate, per oz.....	0.47
Soda ash, 58%, per lb.....	0.29	0.35
Sodium bicarbonate, domestic, per 100 lb...	1.60	1.70
Sodium cyanide, per lb.....	1.80	1.90
Sodium nitrate, per 100 lb.....	3.27	3.32
Sodium sulphide, 30% crystals, per lb.....	0.022	0.023
Strontium nitrate, per lb.....	0.40	0.50
Sulphur, crude, per ton.....	35.00
Zinc dust, per lb.....	0.22	0.26
Cresylic acid, refined No. 5, per lb.....	0.19	0.22
Pine oil, steam distilled, per gal.....	0.58
Pine oil, destructively distilled, per gal....	0.46
Pine-tar oil, per gal.....	0.19
Pine tar, thin, per gal.....	0.18
Turpentine, crude, per gal.....	0.38
Creosote, coal tar, neutral, per gal.....	0.155
Creosote, coal tar, acid, per gal.....	0.215
Coal tar, thin, per gal.....	0.11
Barytes, white, per ton.....	25.00	35.00
Feldspar, per ton.....	8.00	12.00
Talc, American, white, per ton.....	10.00	13.00
Chrome brick, per ton.....	120.00	130.00
Magnesite, Grecian, dead burned, per ton..	85.00	90.00
Ferro-manganese, per ton.....	175.00
Ferro-molybdenum, per lb.....	4.00
Ferro-tungsten, per lb.....	2.75

RECENT PATENTS

1,204,231. AMALGAMATOR. Willson Percival Alderson, Timmins, Ontario, Canada. Filed Feb. 19, 1916. Serial No. 79,329.

1. An amalgamator comprising a horizontally disposed conical drum rotatably mounted on suitable bearings and having a pulp inlet orifice at one end and a pulp discharge orifice at the opposite end, of means for feeding the mercury into the large end of the drum and carrying it gradually forward toward the small end, and means for discharging the amalgam from the small end of the drum.

1,204,069. AGITATOR FOR ORE TREATMENT. Cyrus Robinson, Mount Vernon, N. Y., assignor to Metallurgical Engineering & Process Corporation, a Corporation of New York. Filed Oct. 1, 1910, Serial No. 584,868. Renewed Mar. 30, 1916. Serial No. 87,850.

1. In a device of the class described, the combination of a receptacle, a baffle plate, means for projecting separated minute sub-masses of a mixture of ore and solvent solution from the receptacle violently against the said plate, and a second receptacle for receiving the mixture deflected from the said plate, substantially as set forth.

1,201,899. HYDROMETALLURGY OF COPPER. Edward Ray Weidlein, Thompson, Nev., assignor to Metals Research Company, New York, N. Y., a Corporation of Maine. Filed Aug. 31, 1915. Serial No. 48,150.

1. The method of precipitating copper from copper sulfate solutions by means of sulfur dioxide, which comprises circulating such solution, together with the sulfur dioxide, in a continuous manner through a precipitating apparatus and heat-

ing the same therein to a sufficient temperature and pressure to effect precipitation of the copper and form a residual leach liquor of relatively low percentage in copper as compared with its original copper content, drawing off such leach liquor in a continuous manner, and circulating the same and the ingoing solution in heat interchanging relation with each other, and thereby cooling the hot leach liquor and preheating the ingoing solution; substantially as described.

1,201,386. CYANIDING-TOWER. Albert F. Tanner, Greenfield, Wis., assignor to Ideal Continuous Cyaniding Process Company, Davenport, Iowa, a Corporation of Iowa. Filed July 14, 1915. Serial No. 39,735.

1. A cyanid plant, comprising a series of inclined pans each arranged above the preceding pan in the series with its higher end above the lower end of the said preceding pan, and elevating means adjustably mounted at the lower end of each pan for lifting material therefrom into the upper end of the succeeding pan in the series.

1,201,934. APPARATUS FOR CONCENTRATING ORES. John M. Callow, Salt Lake City, Utah, assignor to Metals Recovery Company, Augusta, Me., a Corporation of Maine. Filed Mar. 4, 1916. Serial No. 82,185.

1. The combination with a plurality of porous bottom, gaseous-bubble separatory tanks, the initial tank having a tailings chamber with a normally slightly open outlet for coarse sands, of a connection between said tanks having one end communicating with said tailings chamber above but proximate to the tailings outlet and having the other end leading into the head end of another tank, said connection having such capacity and discharging in such proximity to the pulp level in the initial tank as to maintain a classifying current in the tailings chamber.

1,203,372. SEPARATION OF METALLIC SULFID ORES. Fleury James Lyster, Broken Hill, New South Wales, Australia, assignor, by mesne assignments, to Minerals Separation American Syndicate (1913) Limited, London, England. Filed May 8, 1913. Serial No. 766,346.

1. A process for the separation of lead sulfid from zinc sulfid in ores containing mixed lead and zinc sulfids, which consists in subjecting the said ores to a flotation separation treatment by agitating them with a frothing agent in a non-acid solution of the mineral acid salts of metals which form basic hydroxids, and thereby separating the lead sulfid from the zinc sulfid.

No. 1,203,373, 1,203,374, and 1,203,375, entitled 'Concentration of Ores,' were also granted to the above patentee for flotation improvements.

1,203,901. CRUSHING-ROLL. Ray C. Newhouse, Milwaukee, Wis., assignor to Allis-Chalmers Manufacturing Company, Milwaukee Wis., a Corporation of Delaware. Filed July 18, 1914. Serial No. 852,116.

1. In a crushing roll, a roll core, a plurality of lug plates forming a shell for said core, a plurality of lugs projecting from each of said plates, each of said plates having a longitudinal recess therein adjacent the leading ends of the lugs thereon, and a wearing plate secured to the leading end of each of said lugs and having a portion extending into the adjacent recess.

1,202,534. PRODUCTION OF METALLIC TUNGSTEN. Frederick G. Keyes and Robert B. Brownlee, East Orange, N. J., assignors to Cooper Hewitt Electric Company, Hoboken, N. J., a Corporation of New Jersey. Filed July 6, 1914. Serial No. 849,137.

1. The method of producing pure tungsten which consists in bringing an oxid of tungsten to a fluid condition in an inert environment, maintaining the said condition by Joule heat.

and separating the tungsten from the electrolyzing bath by an electrolytic process.

2. The method of separating metallic tungsten which consists in subjecting tungsten trioxid to a temperature of approximately 2000 degrees centigrade, thereby producing a lower oxid or mixture of oxids conductive of electricity and also thereby bringing the resultant substance to a fluid condition, maintaining such a condition and passing an electric current therethrough.

3. An electrolytic apparatus comprising a bath of fluid oxid of tungsten, a rotating tungsten cathode and a highly refractory anode.

4. In a fused electrolyzing bath, a cathode of pure tungsten and an anode consisting of a sintered rod of pure tungsten.

1,202,278. APPARATUS FOR DISINTEGRATING ORES AND OTHER MATERIALS. Arthur Feust, New York, N. Y. Filed July 6, 1914. Serial No. 849,200. Renewed Sept. 2, 1916. Serial No. 118,253.

1. In an apparatus for disintegrating ores and other material, the combination of a rotating shell having inlet and outlet openings, formed at its interior to a continuous and unobstructed surface from one opening to the other, the curvature of the shell adjacent one opening being substantially hemispherical and the curvature of the shell adjacent the other opening being substantially paraboloidal or semi-ellipsoidal, and a plurality of differently sized freely movable crushing bodies within the shell co-acting with the said varyingly curved surfaces at the interior of the shell, adjusting themselves according to size, and to the curvature of the interior of the shell.

1,204,843. PROCESS OF EXTRACTING METALS FROM THEIR ORES. Sidney E. Bretherton and Frank L. Wilson, Berkeley, Cal. Filed Dec. 23, 1912. Serial No. 738,126.

1. The process of removing zinc from zinc sulfid ores, which consists in pulverizing the ore, roasting it to convert the zinc content into basic sulfates, then subjecting the roasted ore to the action under pressure of a solution containing ammonia and carbon dioxid which dissolves the zinc content, then heating the solution to precipitate the zinc as a basic carbonate and removing the precipitate from the solution.

1,204,926. PROCESS FOR TREATING COPPER. Frank L. Antisell, Perth Amboy, N. J. Filed Feb. 16, 1911. Serial No. 608,935.

1. The process of refining copper, which consists in melting the copper and then subjecting the molten copper to the action of a purifying agent and then conducting it under a blanket.

2. The process of refining copper, which consists in melting the copper and then subjecting the molten copper to the purifying action of a blanket or cover of a non-metallic salt.

3. The process of refining copper, which consists in melting the copper and conducting the molten copper under a blanket or cover of boron trioxid.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

STATISTICAL REVIEW OF 1916.—SILVER DISCOVERIES.

An output of 455,729 tons of ore, with a gross value of \$16,169,558 in 1916, gave the Leadville district a new record, with the possible exception of the total in the early 80's when, it is stated, over \$17,000,000 was extracted from the mines of Lake county. It is, however, not known upon what system early-day data was compiled, so there is some doubt about this previous record.

Although the quantity of ore shipped from Leadville mines during 1916 is not as large as that in 1915, the value is an increase of \$274,328. The average value of ore marketed in 1915 was \$29.80 per ton; last year the average was \$35.50, an increase of \$5.70. This remarkable advance was mainly due to an increase of 16c. per ounce in the price of silver. The strong silver market that prevailed during the third and fourth quarters of the year caused unusual development in the silver-producing mines, with the result that the silver output for 1916 shows an advance over the previous year of 367,736 oz. The copper output shows an increase of 671,012 lb. over 1915. This metal, 10 cents higher than in 1915, was the other large factor in the increase in the average value. The 2-cent advance in lead was also important, and it is interesting to note that the output last year was greater by 5,238,433 lb. Spelter, on the other hand, registered a drop, the output being lower than in 1915 by 899,182 lb., in spite of the fact that the tonnage of zinc-bearing ore extracted in 1916 was materially greater. The loss in value of the spelter output was \$966,493. Gold also showed a decrease, the difference being \$603,315. This loss proved to be a surprise, but it must be recalled that during the past year there was a marked falling-off in the extraction of high-grade ore from the gold mines. The Ibez and the St. Louis tunnel, which in 1915 enjoyed a most prosperous year, produced but three small lots of rich ore in the last 12 months. Estimates made early in the year that the 1916 total would be above \$18,000,000 proved excessive, but if the zinc-content of the zinc-bearing ores had been maintained to the percentage of the previous year this figure would undoubtedly have been exceeded.

1915 output:	Quantity	Market value	Total value
Gold, ounces	115,121	\$20.670	\$2,379,551
Silver, ounces	2,733,646	0.498	1,361,356
Lead, pounds	18,534,052	0.046	865,540
Copper, pounds	2,254,268	0.171	387,058
Spelter, pounds	74,208,015	0.130	10,276,725
Manganese, tons	6,250	100.000	625,000
Total value			\$15,895,230

1916 output:	Quantity	Market value	Total value
Gold	85,933	\$20.670	\$1,776,235
Silver	3,101,376	0.656	2,037,015
Lead	23,772,485	0.068	1,624,849
Copper	2,925,280	0.272	796,437
Spelter	73,308,833	0.128	9,310,222
Manganese	11,360	55.000	624,800

Total value\$16,169,558

The gain over 1915 was..... \$274,328

Aside from the great value of the production in 1916, other

works of importance to the future development of the district were commenced during the period. The entrance of several large companies bent on undertaking extensive mining enterprises brought about a change, and it is now apparent that the change is one that was greatly needed. These concerns have grouped together and concentrated into individual projects several large areas of valuable ground that previously were in the hands of numerous small leasing companies, or idle. Development in these tracts in the past has been continued on an essentially inexpensive basis. Mining has been done in a rather slipshod manner, with little attention being given to anything save economy and tonnage and, as a rule, the economy was costly. Under big company control, an entirely different policy is being carried out. Every preparation has been made to operate on a broad and highly efficient basis. Expensive and powerful modern plants have been installed. The finest electric pumps available have been secured for draining, and underground development has been outlined on a larger scale than has yet been undertaken here. The much needed capital necessary to make big mines at Leadville finally has been obtained, and these mines are now in the making. As progress of the Down Town Mines Co., Empire Zinc Co., U. S. S. R. & E. Co., Iron Silver Mining Co., and Yak Mining, Milling & Tunnel Co. was chronicled in the *PRESS* during 1916 there is no need to repeat it in this review.

The Prince of Wales Leasing Co., operating the old Bartlett tunnel on Sugar Loaf, has just discovered the richest silver vein that has been opened in the district for years. Where cut, the shoot is 8 ft. wide with 2½ ft. of high-grade silver ore on either wall, and 3½ ft. of talc carrying 41 oz. running through the centre. The entire face averages \$200 per ton. The side streaks that show wire and ruby silver throughout will average \$1000 per ton. The strike was made by work carried on from the bottom of a 700-ft. winze near the 1700-ft. point in the tunnel. An electric hoist will be installed immediately, and a large quantity of the rich ore extracted.

The old Griffin mine at St. Kevin, reported to be the foundation of the fortune made by the late T. F. Walsh, who operated the property during the early days of the district, is again looming up as one of the richest silver producers in Lake county. A new vein 12 ft. wide, showing a lot of wire silver, has been opened, and preparations are being made to make a large output. The Griffin is 3 miles from the nearest siding, making it necessary to haul the ore that distance by team. New stables are being erected at the siding where 40 horses will be kept. A large boarding-house is under construction at the mine, it being planned to increase the force to 50 men as soon as possible. The property will produce at the rate of 60 tons daily. The Griffin is owned by Lucien W. Smith, manager of the Mt. Champion mine.

OATMAN, ARIZONA

LATEST DEVELOPMENTS BRIEFLY DESCRIBED.

The Gold Road mine has opened a good shoot in the north branch of the main vein 4000 ft. north-east of the old glory-hole. The main vein splits near the Billy Bryan shaft, and work hitherto has been confined to the south branch. Recently a cross-cut was driven to the north branch, a distance of 160 ft. Four feet of ore was cut, then some waste, behind which was seven feet of ore, making a total of 11 ft., which

is of excellent milling grade. Another cross-cut has been started 300 ft. back toward the junction of the two branches. The company is also doing considerable work in the Billy Bryan shaft, which, in the early days of the mine, produced 110 tons of ore that yielded \$110,000. The mine was bought four years ago by the United States Smelting, Refining & Mining Co. It has a 300-ton cyanide mill that has been idle since July.

A. C. Werden, manager of the Gold Ore, which lies north-east of the Gold Road mine, announces that the company will soon start construction of a 30 or 50-ton cyanide mill. H. Irving Jones of Denver has been employed to design the mill, and is here to look over the ground. The company sent 2000 tons of \$14.50 ore to the Gold Road mill in four months last year. One lot of 26½ tons assayed \$480 per ton. A winze from the 530-ft. level was sunk 33 ft. in 5 ft. of ore that averaged \$40 per ton.

The Gold Road Bonanza is cross-cutting at a depth of 525 ft. for a 4-ft. vein that dipped through the shaft a few feet below the 500-ft. level. The average of 60 samples taken from this vein was \$30 per ton. It is thought to be a branch or spur from the main vein, and will be followed by a drift.

have been hindered by a heavy flow of water, and new station and electrically driven sinking-pumps have been installed. A 900-ft. Sullivan compressor was received last week for use at this shaft.

Shaft-sinking is in progress at the Big Jim mine. The shaft has been sunk 55 ft. from the 485-ft. level. A station will be cut at 600 ft. and a cross-cut driven to the vein, about 90 ft. Of this work, Horace V. Winchell, who examined and sampled the mine in December last, said in his report: "A level at the depth of 600 ft. will in all probability double the value of the estimated ore, and is likely to encounter some of the bonanza shoots for which the district is famous." The company is working on plans for a 400-ton cyanide mill.

JOPLIN, MISSOURI

REVIEW OF THE MISSOURI-KANSAS-OKLAHOMA ZINC-LEAD REGION IN 1916.

Again the Missouri-Kansas-Oklahoma region has made new records in production and value of its zinc and lead products. The year 1916 yielded the greatest quantity on record; namely,

VIEW OF OATMAN DISTRICT, ARIZONA.

On the right is the Aztec shaft of the Tom Reed company; Big Jim shaft behind. On the left, behind knoll, is the Gray Eagle shaft of the Tom Reed; behind this is main shaft and mill. In centre background is Oatman. On knoll in background to right of town is No. 2 shaft and mill of United Eastern.

On the 400-ft. level, the Adams Mining Co. has drilled into the hanging wall of the vein. The holes released much water and will not be shot until a bulkhead is put in. The Adams is in the Black Range section of the district, and has a good surface showing.

There is much discussion of a strike of high-grade ore in the United Eastern mine. The company refuses to divulge information concerning it. Local reports are that a streak of rich ore on the hanging wall has been opened on the 300, 445, 565, and 665-ft. levels, which varies from 4 in. to 6 ft. in width. Some rich specimens have been seen. The new mill is reported to be working satisfactorily treating 200 tons per day. According to official reports made last summer, the average throughout the mine is \$25 per ton.

Extensive development continues in the south-east of the Tom Reed. The Aztec shaft is down 460 ft. having cut the vein at 430 ft., and it is expected to get through the vein at 480 ft. The better ore appears to be on the foot-wall side, an average grab sample taken recently assaying \$57. Operations

349,690 tons of blende, 28,779 tons of calamine, and 53,326 tons of lead ores. No previous year approached this great quantity, the nearest being 1915 when the output was 56,317 tons less of blende, 8210 tons of calamine, and 7281 tons of lead. The blende concentrate was valued at \$29,693,214, which was double the value of previous normal years, and \$6,814,819 greater than the previous record output of 1915. The value of calamine totaled \$1,773,118, a record for this ore, and \$682,597 greater in value than in 1915. The value of lead ore was \$4,488,986, more than double the value of previous normal years, and \$1,974,673 ahead of the output of 1915. With such figures it is no wonder that the Joplin district last year was a hive of industry and experienced the greatest prosperity it has ever known.

PRICES. While the total value of the ores was more in 1916 than in 1915, one record was not greater; namely, the price of \$135 per ton for zinc concentrate (60% metal) during one week in 1915 was not reached in 1916. However, the average price paid for blende, \$84.91, for 1916, was \$6.93 above the

average of 1915. Taken as a whole therefore, the market prices for zinc ore in 1916 was higher and more steady. In January the price opened strong, showing an average of \$99.82 during the month for all grades. February saw a distinct stiffening of the market, which rose to \$125 for some lots of high-grade ore, these being the highest prices paid during the year. The average of the month was \$108.90 on all grades. The market sagged a little in March, but no slump was noticeable, the average being maintained at \$99.10. April saw extremely heavy buying, and under the stimulus of this great demand prices again advanced to the \$125 level, and sufficient quantity was sold to show an average of \$106.45 for the month. This was one of the best months of the year, 43,747 tons of blende and 4080 tons of calamine being marketed. Then the market began to weaken under the stress of less demand and by August prices had dropped until the average was \$56.60. Thenceforward there was a gradual advance for zinc until the first three weeks of December, when the base price again went over the \$100 mark. The peace rumors flattened out the zinc market, there being a drop from a maximum of \$115 to a minimum of \$70. The average for the entire month was \$87.26.

The prices of calamine opened as firmly as blende in January, and while the shipment was small, the average for the month was \$74.15. The market held uniformly firm until April, when prices leaped upward along with blende, and calamine registered its high mark of \$81.62 on an average for the month. The market went down from then on until the end of October, that month registering only \$39.68 as an average for the month's shipments. November and December showed improvements in demand, practically one-fourth of the entire year's shipments being made in those two months. Under the stimulus of this demand prices again rose above the \$50 mark for monthly averages.

PRODUCTION AND SURPLUS STOCKS. Production was marked off into three periods in 1916. The first four months of the year were the periods of heavy demand and high prices, and while production was fair, the winter conditions were such as to hinder maximum production. The stimulative action of high prices, however, was making itself felt, and the next four months showed the results of this stimulation by the extra activity at the mines and mills that had been put into the production column under the promise of the prices paid the first four months of the year. From an output of 7500 tons per week in January, this rose to 10,000 tons in June and July. At this period prices were growing lower, and the extremely severe drought was having its effect in curtailing production. This heavy production resulted also in raising the surplus stock of 4000 tons in January to 32,250 tons by the end of July. This was the largest quantity of surplus stock that has ever been accumulated in the Joplin district, and was long considered as a serious factor in depressing the local zinc-ore market. Owing to the accumulation of the surplus stocks and the lowered prices, coupled with the drought and the lack of electric power, production again ebbed, and when the heavier demand began to make itself felt in November and the earlier part of December, when the shipments approximated 10,000 tons per week, the surplus began to dwindle, and by the end of the year had reached approximately 1500 tons, the lowest point for the whole of 1916. The tide is gradually rising again and the output is now close to 8000 to 9000 tons per week. Were fuel and power conditions normal, the output would be nearer 10,000 tons.

What has been said of production and surplus stocks of blende applies in the same proportion to lead, the same ebb and flow of production and surplus being noticed, and practically for the same reasons. The year opened with 1435 tons of surplus. By the end of April it was down to 750 tons, after the heavy buying of that month at record price. With the decline in value there was also an increase in the surplus, and by the end of July 2680 tons had been accumulated and reason-

ably heavy shipments were made also. Thenceforward, the surplus dropped quickly, and at the end of October practically every bin was empty. By the end of December the stock-pile had accumulated to 400 tons.

The following tables gives the blende, calamine, and lead ore shipments, prices, value, and surplus stocks for each month of 1916:

ZINC-BLENDE SHIPMENTS, PRICES, VALUE, AND SURPLUS STOCKS FOR 1916:

Month	Tons	Average prices	Value	Surplus stock at end of month
January	26,126	\$99.82	\$2,608,002	4,000
February	27,465	108.90	2,991,309	3,000
March	24,924	99.10	2,470,298	10,465
April	43,747	106.45	4,658,014	8,200
May	26,840	90.14	2,419,382	17,190
June	26,077	74.26	1,936,485	23,650
July	26,947	67.72	1,825,050	32,250
August	16,147	59.11	954,477	32,230
September	31,074	56.60	1,758,711	18,820

Total	53,326	\$84.18	\$4,488,986

While lead ore was longer in reaching its maximum height, this year's levels were the best ever known here. At least two months (April and December) of the year showed base offerings above \$100 for 80% lead-content. The market opened between \$70 and \$80, and gradually rose to the high record in April when the average for the entire month was \$100.44. At these prices shipments were over 6000 tons, the greatest of any month of the year. The market then went down by gradations

until August, when the trend started again in the upward direction. December showed an average for all grades of \$91.70.

NEW DEVELOPMENTS. All of the main centres of the region have shown increased production, but to the Oklahoma districts must be handed the banner for the largest increase in output and the most important developments during the past year. While the Oklahoma centres have shown remarkable growth from the moment of their inception, it took the unusual prices of the past two years to bring out their merits and call the attention of mine operators who had become fixed in the older camps of the field. This year, week by week, has noted the gradual increase of the production of the Oklahoma districts up to May. From then on production bounded up until for many weeks they led the entire region, and promise to be the most important producers here for some time to come. From a single area at Commerce the district has now expanded to four others. Besides Commerce, there is Cardin, Century, Picher, and Quapaw. From a little group of mills at Commerce there are now these five main groups, together with many connecting mines between. Nor does the development stop with the State line, the new prospecting and development work has been carried across into Kansas, and now stretches northward to a point north-west of Baxter Springs, Kansas.

MILL BUILDING IN THE NEW FIELD. At no time and in no

CHARACTER OF THE NEW DISCOVERIES. The earlier discoveries of zinc and lead ores at or near Miami in the old Commerce district were at shallow levels, and the ores contained large amounts of pyrite and bitumen. Both of these ingredients brought down the grade of the ore and seriously interfered with concentration. This place later developed ores at lower levels that were free from these deleterious substances. The new discoveries have been principally around 160 to 220 ft. in depth, and these generally have been free from the bitumen or pyrite. The faces are usually high, and the ore carries from 5 to 25% lead and zinc. The ore concentrates to a 60% blende concentrate or even better, while the lead will concentrate to 80% concentrate or over. Owing to the high value of the ores the capacity of the mills is not as good as the same class of plants in the sheet-ground district. Mining conditions have been rather difficult owing to the large flow of water which always prevails in any new centre, and which in this district has proved not only heavy but of more or less artesian character. For this reason it has taken a great deal of pumping to reduce the pressure, and even then the drainage is within limited areas, making it necessary for any new group of mines or new mine outside of the drained area to fight the heavy water from the start. This has made shaft-sinking expensive, and it has necessitated comparatively slow development. Other difficulties in the way of operating conditions lie in the absence

of rock roads and a main-line railroad directly through the district. Practically all developments lie two to four miles from the main line of the Frisco and M. O. & G. lines. A small branch road comes out from Miami through the Commerce, Picher, and Cardin districts now, but this is entirely inadequate for the needs of these places. Much of the heavy machinery has been hauled by motor-trucks and teams, and with bad weather and soft roads this soon brings a condition of practical impassability in some places. Road conditions, however, are being improved rapidly. A fairly good rock road has been completed all the way through from Miami to Joplin, and with the completion of side roads it will not be long until this feature of operations will become normal. The building of bridges over streams at Tar creek and its branches that ramify through the new centres will also improve conditions in

other district has there ever been such a large number of mills constructed within so short a period of time. Fully 40 mills have been constructed in the Oklahoma section during 1916, the period of mill construction has not ceased. It is now at its height, and the first six months of 1917 will probably be as great a period for mill construction, and may perhaps be greater than the past half-year.

DRILL PROSPECTING. Another peculiar feature of development in this new Oklahoma and Kansas field is the amount and character of the prospect drilling carried on. In this field there have been from 150 to 250 drill-rigs at work throughout the year. One could stand in one spot on the prairie and count from 65 to 100 rigs. In this respect the field resembled more an oil-field than it did the ordinary zinc-field of the older portions of the region. The results of this drilling campaign have been remarkable. Not only have these prospectors opened new ground, but the deposits discovered have been the richest so far found in this region. With so many strikes made of such uniform richness there has naturally been attracted to the field not only a large number of new prospectors, but among them has gone practically every important zinc-producing company in the United States. It is not often that a single district commands the mining resources of an entire industry, but the new Oklahoma and Kansas field has been fortunate in this regard.

that field and will greatly facilitate operations.

TREND OF NEW DEVELOPMENTS. Most of the new development in Oklahoma has extended from a point two miles north of Miami in a north-easterly direction. This trend has continued north-east across the State line into Kansas, and a connecting line of drills now runs from a point one mile north and west of Baxter Springs, south-west to Commerce. Along this line there are points where development has been wider than others, but whether the trend is caused purely by the locations of the development or whether the deposits simply lie in this direction remains yet to be proved by more extensive prospecting. There are some indications, however, that there are some cross-trends of ore-channels bearing off from this main developed trend. This seems to be shown by the work running from Cardin south-east through Century to Quapaw, and from Cardin north-west a distance of four miles. It is also apparent from recent discoveries that there is an area south-west of Columbus, Kansas, which may be connected up with the main developments near Picher, through discoveries of ore near Melrose, Kansas. This means an extension of the field westward a distance of 10 to 14 miles, and opens possibilities of new territory of amazing extent. Acting on the working hypothesis that the main trend of ore so far discovered and running from Commerce to the Baxter field will eventually connect up with the developments around the Badger-Peacock and Lawton dis-

tricts, there have been a number of operators taking up leases along this line, who have even extended their operations north-east of Badger-Peacock and Lawton as far as Waco, Kansas, and Asbury, Missouri.

Whether this theory be true or not there have been some excellent strikes made near Waco, Kansas. These have been of the same character as those west and south-west of Baxter Springs, and in Oklahoma. Drills penetrate the usual thickness of Pennsylvanian shales and sandstones, then pass into Mississippian limestones and chert and catch the ore deposits at 160 to 220 ft. It would appear from the way leases are now being taken, and the way drill prospecting is being located, that the major portion of the next year's new development will lie in the territory stretching from Waco, Kansas, south-west past Baxter Springs. This will add a long strip of country to the western portion of the district, and will greatly increase the importance of Kansas as a zinc-producing State.

MISSOURI DEVELOPMENTS. Owing to the unusual excitement regarding the Oklahoma and Kansas discoveries there has not been the usual attention given to new developments on the Missouri side of the zinc district. This does not mean that there have been no new developments, but that their number is small compared to those already mentioned. Results in Missouri have been more in the way of ordinary extension within the limits of the old centres. At Duenweg there have been important additions to ore reserves through the drill prospecting carried on by Molloy and Cameron on the Hall land. Here some of the best sheet-ground discovered for years has been tested and proved. Throughout Duenweg there has been stimulated by this discovery renewed activity which has resulted in building of several mills, and the addition of considerable tonnage to the weekly output.

Joplin men—L. C. Church and J. H. Wright—are heading the Tri-State Mining Co., recently formed with a capital of \$500,000 to operate from Century and Picher to Baxter Springs, Kansas. Drilling is to cost \$100,000 on the 2000 acres held. The Butte & Superior company is drilling in adjoining ground.

In a building 90 by 110 ft. the Oronogo Mutual Mining Co. is to install an Allis-Chalmers engine, General Electric 1200-kw. generator, and 2600-cu. ft. air-compressor, costing in all \$70,000. Two water-tube boilers of 400 and 350-hp. will supply steam.

The old Aurora district has been the scene of considerable prospecting and development. Among the new mines brought out by the prospecting which have shown remarkable records was the Red Wasp. This property has developed into one of the richest producers of the entire region. Other properties which have been revived have been the United Zinc Co. tracts and their sub-lessees. Still farther east at Springfield there have been a number of new properties opened at the junction of Pierson creek with the James river. There has also been a revival of mining operations at Ash Grove and Greenfield. The operations have not been of large extent nor importance.

ARKANSAS DEVELOPMENTS. Stimulated by high prices, many attempts have been made to revive operations in various parts of northern Arkansas. Most of the new activities however have been in the Rush district. Here a number of the old properties have been re-opened, and in some cases new deposits discovered and developed. Among the better producers of the year have been the Edith, Red Cloud, Yellow Rose, and Silver Hollow. Practically every little place in north Arkansas has received attention. Properties around Yellville, Harrison, Dodge City, Mountain Home, Ponca City, Jasper, and St. Joe, have been the scene of considerable new prospecting, which has resulted in some discoveries of ore. The production for the year will be materially larger than for many years. The only producer of exceptional merit developed during the year in the Arkansas field was the Edith mine in the Rush district. There was also more or less prospecting in south-western Arkansas near Vandervoort and Gilham and across into Oklahoma, but this has not resulted in any workable deposits of ore so far.

TORONTO, ONTARIO

GOLD MINING IN 1916.—PORCUPINE NOTES.—STEEL OUTPUT.

The past year has been characterized by a remarkable expansion of gold mining at Porcupine and the newer gold districts, and increased interest and confidence on the part of investors as to the future. Numerous prospects have been developed to the producing stage or are rapidly approaching it, and there is every likelihood that before the end of 1917 Porcupine will have at least 20 producing mines. Great advances have also been made in the Boston Creek, Kirkland Lake, and Munro Township areas, and large sums of American capital are being attracted.

During December the Dome Mines produced \$183,300 from 39,000 tons of ore of the value of \$4.70 per ton. The working cost was \$2.77 per ton, a reduction of 11c., which is an excellent showing considering the high cost of materials. A rich strike recently made at the 700-ft. level is stated to assay \$14 per ton across a wide vein.—The 4-weekly statement of the Hollinger Consolidated for the period ended December 1, shows gross profits of \$240,075 from the treatment of 50,304 tons of \$8.78 ore. The working cost was \$3.74 per ton. The mill ran 90.5% of the possible running time. The construction work now in progress resulted in a deficit of \$238,703.—At a meeting held in Toronto on December 28 the shareholders of the McIntyre ratified the arrangements for a merger with the McIntyre Extension and Jupiter companies and authorized an increase in the capital from \$3,000,000 to \$4,000,000. The company has taken an option for one year on the Plenaurum, adjoining the Jupiter, and agrees to spend \$53,000 in its development.—The Schumacher is diamond-drilling in the 300-ft. level to pick up the high-grade vein found on the 100-ft. level south of the main workings. Gold-content of the ore sent to the mill from the upper level is better.—A rich strike is reported on the Gold Reefs property in a narrow vein encountered on the 50-ft. level.—At the Davidson a raise has been made from the 100-ft. level to the surface, and an intermediate level at 50 ft. will be driven to prove the main orebody. On the 300-ft. level the vein is showing satisfactorily and a substantial tonnage of high-grade ore has been exposed.

The power-line to Kirkland Lake is approaching completion and is expected to be in operation about February 1, when active development will be at once undertaken on several properties.—La Belle Kirkland has opened a vein system to a depth of 350 ft., and blocked-out a large orebody, and has gone down 100 ft. on another vein. Diamond-drilling is being undertaken to prove both bodies at depth.—The Minaker claims have been acquired by Rochester capitalists, and surface exploration is being carried on.—The Hunton-Kirkland property, comprising 40 acres, has passed into the control of H. Cecil and associates of New York.

At Boston Creek, the Boston Creek property, comprising over 100 acres, is being developed on an extensive scale with J. R. Rutherford, a graduate of McGill University in charge. About \$250,000 has already been spent and the value of ore blocked out is estimated at \$1,500,000. The vein has widened from 4 ft. at the surface to 12 ft. on the 200-ft. level, and the gold-content is reported to be high. Power is obtained from the Northern Ontario Power Co.'s line.—The O'Donald group of claims adjoining the Boston Creek, and embracing 190 acres, have been taken over on option by the Crown Reserve of Cobalt. Camp buildings are under construction and surface work has been commenced preparatory to development.

An official statement of the output of the Dominion Steel Corporation of Sydney, Nova Scotia, for 1916 shows that the past year has broken all records owing to the enormous demand for steel for the manufacture of munitions. The production of pig iron was 348,000 tons, being 12½% in excess of the previous year's output, and steel ingots were produced to the amount of 376,000 tons, an increase of 8%.

The news of the week as told by our special correspondents and compiled from the local press.

MIAMI. At the coarse-crushing plant of the Inspiration Consolidated, No. 4 section has recently been fitted with the necessary equipment for screening-out fine material that it is unnecessary to send to the secondary crusher. Heretofore in this section all the product from the gyratory-crushers was fed to the Symons disc-crusher, the fine material thus occupying uselessly valuable space within the crushing area of the machine. By screening-out the fine and passing it around the Symons

Appeal of the Miami from the decision of the United States Court in Delaware in the flotation suit will be heard this month, arguments to be heard January 29 at Philadelphia.

During the past 18 months the Arizona State Bureau of Mines has issued 50 bulletins on various subjects of interest to the people of the State. It is the aim of the Bureau to have eventually a bulletin that will cover practically every inquiry that comes to the office, although it will be some time, of course, before this is realized. The Bureau has recognized the difficulty of giving, in individual letters, as complete information as is often desired, and considers that a bulletin, even a short one, will prove much more satisfactory. Nearly 100,000 bulletins have been sent from the office during the past year and a half, so the demand for this information is evident.

CALIFORNIA

KESWICK. The Mountain Copper Co.'s 250-ton flotation plant is being doubled in capacity. A leaching plant is to be erected. Ore and concentrate are sent to the company's smelter at Martinez on San Francisco bay.

MARYSVILLE. In the suit of the Yuba Investment Co. v. the Yuba Consolidated Gold Fields Co. to quiet title to 1639 acres of land at Hammonton, in the Court since last May, Judge E. P. McDaniel decided in favor of the defendant. The land is valued at \$350,000 for dredging purposes.

(Special Correspondence.)—A sale that means much to Sierra City has been consummated within the past 10 days. The Recorder's office at Downieville discloses the information that John C. Mansfield, an old resident of Sierra county, has bonded his Shamrock quartz claims to John V. Powers, the Amador attorney, and that the latter has made the initial payment of \$5000 on a total price of \$100,000. It is understood that a group of capitalists headed by W. C. H. Dibblee, the well-known banker of San Luis Obispo, will take over the property from Mr. Powers, and begin extensive exploration as soon as weather conditions permit. The Shamrock property adjoins the Sierra Buttes mine, which in the past years has sent to the Mint over \$16,000,000 in gold, and is within a short distance of some of the State's past best producers. The Shamrock has never been systematically developed, but has what is considered to be one of the best surface showings in Sierra county. The property comprises 14 claims and water-rights sufficient for all power purposes.

Sierra City, January 18.

(Special Correspondence.)—Results of prospecting with a Keystone drill by the Springfield Tunnel & Development Co. have been exceedingly satisfactory so far. This week rich gravel was encountered in what is known as the Fox channel. It is stated that operations will be resumed in the long drainage adit as soon as the depth of the main channels has been determined. It is estimated that another year's work will be required to complete the adit, whose cost will be approximately \$100,000.

An option for the purchase of the Rawhide No. 2, adjoining the well-known Rawhide mine, has been given by the Hobart estate to H. H. Stambaugh and R. C. Steese, of Youngstown, Ohio. It is stated that in the closing of the deal a good sum changed hands. Stambaugh and Steese have also purchased the surface rights to 30 acres adjacent on the east from the heirs of the late Matthew Arnold. It is understood that work will commence immediately.

A vein on the F. Cavallero ranch, in the outskirts of Sonora, is being prospected under the direction of C. E. Reeves. The vein, which is supposed to be the same as the Gerrymander, a mine that was worked to a considerable extent a number of years ago, has been exposed in several places by shallow shafts and open-cuts, and the showing has been most gratifying. The sinking of a permanent working shaft is contemplated.

The drift at the 160-ft. level in the Chilano mine, near Tuttletown, has been driven into a body of rich ore, a streak of the vein being liberally speckled with gold. The property, owned by Gillis, Booker and Harkinson, of this county, was recently bonded to F. W. Bernard, of Beverly, Massachusetts, with whom it is understood other men of the East have become associated. Only a few men have been employed, but it is thought the strike just made will induce the bond-holders to undertake operations on a larger scale.

Sonora, January 12.

(Special Correspondence.)—A new pump has been installed at the 1400-ft. level of the Old Eureka shaft, and excellent headway is being made in lowering the water as well as in re-timbering the shaft below that point. The new head-frame is almost completed, and will be ready to operate as soon as the

electric equipment is complete. Men have been engaged in placing the large hoist on its foundations, and getting everything ready for making connections as soon as the motors can be installed. No attempt will be made to fill in the low ground around the shaft-collar to the level of the engine-room until the hoist is in operation, when the waste from the mine will be used for this purpose.

At the Central Eureka mine sinking for a sump below the proposed 3350-ft. level is in progress. As soon as the necessary room is provided for sump and shaft chutes, a station will be cut and driving started both north and south on the ore developed in the course of sinking, at a point 150 ft. below the present lowest level, 3200 feet.

Contrary to expectations, sinking the Bunker Hill shaft an additional 600 ft. has been delayed owing to the necessity for straightening a bend in the shaft that occurred in previous sinking operations. In the last 100 ft., the shaft veered about 4 ft. to the south. Men are now engaged in adjusting this by cutting into the north wall of the shaft and moving the timbers into line. Some weeks' time may yet be required before this adjustment is completed, after which the proposed new work will be started.

The Argonaut company has almost completed the new mill west of the shaft, 20 heavy new stamps having been installed. As soon as these are ready to drop, 20 at a time will be removed from the old mill to the new and the remaining stamps kept in operation, so no unnecessary time will be lost. When the last battery of the old mill is removed to its new place, the Argonaut will be equipped with a modern 60-stamp mill. M. Latham and J. Simonds of Melones, Calaveras county, have secured an option on the tailing stored below the old mill, and they contemplate treating this by a 150-ton cyanide plant. Over 200,000 tons has been stored in this dam, which, according to recent tests, assay from \$1.75 to \$2.50 per ton. As these men have successfully treated tailing dumps in Calaveras county, their operations here will be watched with interest. From the new mill, the tailing will flow by gravity to the Eastwood dam erected during the past year.

An electric hoist is being installed at the North Star shaft of the South Keystone property, and it is expected that the actual work of unwatering the shaft will begin about the middle of January. Engine-room, compressor-house, and other mine buildings have been erected.

Suit has been commenced in the Superior Court of this county by the Original Amador Consolidated Co. against James E. Bastian, the company having filed complaint in ejectment, alleging that defendant entered upon the Last Chance Lode claim, part of the Little Amador group, and unlawfully ousted plaintiff from a portion of said premises. The mining company demands not only possession of the disputed ground, but \$5000 damages and costs of suit. A similar suit for \$5000 damages is pending against Frank Gallardo on complaint filed by the same company.

Rumors are afloat to the effect that a strong syndicate is about to bond the South Jackson and the Moore mine near Jackson. The last company operating the South Jackson had to abandon its work for lack of capital, at a time when prospects of the early development of pay ore seemed excellent. A three-compartment vertical shaft was sunk to a depth of 577 ft., and levels opened at 210, 345, and 500 ft., from each of which considerable prospecting was done, with the result that three veins were developed, the west, middle, and Zeila. The mine is equipped with electric hoist, compressor, motors, and a 50-ft. head-frame. Maurice and Jeffrey Schweitzer of San Francisco, J. E. Davis of Melones, and F. W. Ruhser, Adam Huberty, and C. P. Vicini of Jackson, are heavily interested in the South Jackson property, while the Moore mine is owned by the Patterson estate of Fresno. The latter has been idle for many years and the workings are caved, but it is only about two years since the South Jackson mine was in operation.

Sutter Creek, January 19.

WEAVERVILLE. Conditions at the Lagrange hydraulic mine are anything but favorable. On the 19th the machine-shops were destroyed by fire; a landslide broke a good deal of flume; and cold has frozen many things.

YREKA. Charles H. Hawkins has brought suit against George A. Milne for \$20,000 damages. He alleges that Milne dumped rocks and tailing to a depth of 20 ft. and 200 ft. long on his mine. During the trial Milne introduced mining location notices to show that Hawkins does not own the land upon which the debris was dumped.

GEORGIA

DAHLONEGA. The past year is considered by the *Echo* to have been a busy one in this gold district, especially in metallurgical improvements at the Crown Mountain and Toledo mines. Several placer mines had a good season. Prospecting continues for other minerals.

IDAHO

LENIA. The Idaho Gold & Ruby Mining Co., operating a placer property at this place in Boundary county, has bought in San Francisco 3000 ft. of pipe and 6 giants, costing over \$12,000. The head will be 420 ft. The sluicing plant is to have a daily capacity of 25,000 cubic yards.

MISSOURI

JOPLIN. Prices for blende ranged from \$60 to \$75 per ton last week. The output of the region was 7341 tons of blende, 142 tons of calamine, and 892 tons of lead, averaging \$70, \$40, and \$87 per ton, respectively. The total value was \$597,864.

MONTANA

BUTTE. On the 2400-ft. level of the Davis-Daly there is 11 ft. of ore assaying 35% copper and 32 oz. silver per ton. The minerals are bornite and glance. For 115 ft. driven on this level, 85 ft. assays 12%.

HELENA. The Scratch Gravel Mining Co. has bought a large building, erected some time ago for the treatment of zinc ore, and will install machinery to treat its ore. Development of high-grade gold ore continues to a depth of 400 feet.

NEVADA

ELY. In its last quarterly statement for the county assessor, the U. S. Tungsten Corporation announces that 457 tons of ore treated yielded \$298,742. The profit was \$125,762, and tax on 80% net \$1573. The plant did not work in the December quarter, but may resume in the spring.

A shortage of coal is curtailing operations of the Nevada Consolidated. The weather is extremely cold.

LOVELOCK. The St. Anthony tungsten mines and mill near Toy have been closed indefinitely.

TONOPAH. Last week's production from 9 mines totaled 9409 tons, valued at \$169,362. During December the Belmont yielded a profit of \$114,836 from 10,204 tons; and the Jim Butler \$22,508 from 2601 tons.

VIRGINIA CITY. In sending out an assessment (10c. per share) notice, the Mexican company gave the following information:

"The work of lowering the water from the 2700 to the 2900-ft. level of the north-end mines was commenced a short time ago, the pumps being lowered in the winze sunk many years ago on the south line of the Mexican mine. Most satisfactory progress has been made, the water having been lowered nearly 100 ft. at this writing (January 9), the lowest point it has stood in the Comstock mines for 32 years. Owing to the fact that the winze has to be changed with depth from one of three small compartments to one of two large compartments, progress is slower, but the ability of the electric pumps to handle the water is amply demonstrated. Beginning with January 1

has been commenced the installation of a new and more powerful electric hoist at the Union shaft, the old one proving too weak for the work since the shaft was opened to the 2700-ft. level. It is now the deepest shaft in Nevada, but there is no doubt that the new hoist will easily cope with the work. This is of course done jointly by the Mexican, Union, and Sierra Nevada companies, the owners of the shaft, each company paying one-third. The equipment has been maintained in first-class condition. There are mining supplies and cyanide on hand all paid for worth upwards of \$30,000 and the mill is ready to start at a day's notice on Mexican ore when developed, or on ore from the neighboring mines. In this connection shareholders will do well to remember that there will shortly be entered country that is absolutely unexplored. The management has never doubted the fertility of the Comstock in depth, and with modern methods, both heat and water can easily be mastered if the funds are supplied. With silver going up and water going down the company fails to see why any shareholder should feel anything but encouragement."

NEW MEXICO

(Special Correspondence.)—The United States Copper Co., owner of the Philadelphia mine at Hanover, has recently acquired the Hardscrabble group of copper and silver properties in the Pinos Altos district, 1½ miles north of Pinos Altos and 9 miles north-west of Silver City. The capital of this company has been increased \$500,000 to \$1,500,000. The president, J. W. McAlpine, recently arrived from the East, and plans for extensive development are now under way. Work has already been started at both Hanover and Pinos Altos. At the latter place two vertical shafts, 4 by 8 ft. in the clear, have been started and will be sunk 200 ft. Orders for hoists, air-compressors, drills, etc., have been placed, and the company hopes to have machinery installed and operating by spring.—H. W. Kitson, representing Eastern and Western capitalists, has been in the district for the past two weeks, acquiring 90-day options on 50 claims for examination. The holdings taken over by the U. S. Copper Co. and those under option to Mr. Kitson, are in a new district, partly developed, but showing good indications.

It is said that the flotation plant being installed by the Empire Zinc Co. at the Cleaveland mine will not be completed until next summer. The new engine, the second, is being installed, and with this additional power the mill will be operated three shifts. It is estimated that with flotation machines the mill will have a capacity of 35 tons an hour.

The El Paso Mining Co., which took over the Stauder and Wright mill and the lease and bond on the Savanna holdings, is increasing the capacity of the mill from 35 tons to 100 tons per day, adding flotation. This mill operates the only Huff electro-static separator in this district.

The Kept Woman, a patented mining claim belonging to A. Espelen, and the Jupiter claim owned by L. A. McCarty, the latter joining the former on the south, were purchased on January 10, by Oliver Krull and J. C. Rumball. The Kept Woman has two shafts down about 100 ft. each, connected by a drift, and shows good ore. A small mill was erected some time ago, but was not a success. The new owners are practical men as well as mining engineers, and announce that they will begin active development early in February. They also contemplate re-modeling the mill and adding a flotation annex, the mill to have a capacity of 25 tons per day to start with. Krull and Rumball are from old Mexico, Mr. Krull having been superintendent of the Rio Tinto mine at Terrazas, Chihuahua; and Mr. Rumball, who is a chemist, owning and mining property at Batopilas, Chihuahua.

The present local activity should make Pinos Altos a lively place this year.

Pinos Altos, January 9.

(Special Correspondence.)—On January 1 the Oaks company

paid its second dividend of 1% on preferred stock issued. Shipment of ore to custom mill from the Eberle mine continued during the week.—Campbell & Dempsey, owners of the Golden Bar group in the extreme north end of this district, have run a 248-ft. cross-cut, and are just getting into the vein, which shows high-grade ore on surface.—At the Last Chance mine, the Mogollon Mines Co. has installed timbers and track for skip to the 900-ft. level. The entire shaft will be completed some time in January, giving additional capacity for hoisting and development.—An assistant in the State Engineer's Office is making regular trips here, checking water readings on streams in the vicinity which have been appropriated by local interests with a view of installing hydro-electric power-plants in the early future.

Mogollon, January 9.

OREGON

In the October, 1916, 'Mineral Resources of Oregon,' published by the Oregon Bureau of Mines and Geology, G. M. Butler and G. J. Mitchell give a preliminary survey of the

PART OF OREGON, SHOWING CURRY COUNTY.

geology and mineral resources of Curry county. The text covers 132 pages, with 41 illustrations. Curry county lies in the south-western corner of Oregon, bounded on the west by the Pacific Ocean. Its length is 66 and width 36 miles. The area is mountainous. Gold deposits consist of veins, stream placers, and beach placers. There are occurrences of copper, iron, chrome, platinum in the placers, coal, borax, and quick-silver.

(Special Correspondence.)—Albert Geiser and partners have made one of the richest strikes of gold in Baker county in years at the old Connor Creek, as mentioned in the PRESS of January 6. After doing dead work for two years the vein was cut in the upper adit. It is 5 ft. wide, having a high-grade streak from 6 to 8 in. Some of it is so rich that it has been kept in the safe and is to be melted into bullion at the mine; for this purpose Mr. Geiser sent to Denver for a melting-furnace. The rest of the vein will average from \$30 to \$40 per ton. The ore is a white quartz containing no sulphide. The shoot has been driven on for 100 ft. and a raise started. Two lower adits are being driven to cut the ore at depth. A 10-stamp mill is crushing the ore. This mine is one of the oldest in the State, being first worked in 1876, and is credited by some with a production of over \$3,000,000. The present owners are not working the old vein, but cross-cut to another that from surface indications was thought to exist in this ground.

In the Greenhorn district, E. E. Petty and Henry Abel have a good showing on their Red Bird claim, extracting and mill-

ing some high-grade gold ore. Across Olive creek from the Red Bird, Harvey Abel and Abe Abel are driving an adit in good ore on the same vein.

The Rainbow mine of the Commercial Mining Co. is keeping up a steady production from good ore. Thos. Borman has recently been appointed mill superintendent.

The Cornucopia district is attracting a great deal of attention due to the fine record of the Baker Mines and the Cornucopia Mines companies, which have the best gold mines in the State. The Queen of the West started operations again last summer. F. S. Baillie, former manager of the Columbia mine, is now manager of the Baker; Robert Betts is manager of the Cornucopia. Stages run to Cornucopia from Baker and Robinette.

The Iron Dyke mine near Homestead, now a large copper producer, had a good year and is at present employing a large crew.

M. F. Wyatt of Cottage Grove reports fine results on his claims in the Bohemia district, out from Cottage Grove. Samples of copper-zinc ore from two veins that were cut in the upper adit assay well. The veins are parallel, 20 ft. apart, and each is 5 ft. wide.

Victor Chapman of Eugene has completed work on the Highland group and reports satisfactory results. He and others are working on a porphyry dike that pans well in free gold, and gives good assays. The Highland is on the north fork of the Willamette river, out from Oakridge.

Eugene, January 12.

UTAH

ALTA. About 800 tons of ore was shipped out of the district last week, between 35 and 40 teams being occupied in this work in Little Cottonwood canyon.

AMERICAN FORK. According to J. H. Weber, well-known at Salt Lake City, who returned from an inspection of various properties in the district, it is his opinion that the American Fork Canyon region will be heard from in a few months as one of the big producing sections of the State, as it is even now one of the most active in the development of proved ground and the prospecting of territory that is accounted favorable for development.

GOLD HILL. The new Deep Creek railway is expected to reach this place early in February. The Pole Star copper mine has shipped the first car of ore over the road, auto-trucks carrying the ore to the first siding.

NEPHI. In Juab county two drill-rigs are boring for oil on the eastern anticline. Several years ago two wells were put down 2000 ft., but results were never made known. Mt. Nebo No. 2 well struck oil and gas of high gravity. The Utah Petroleum Co. of Delaware is doing the new drilling.

PARK CITY. Early in February the Judge Mining & Smelting Co. expects to have its zinc-plant at work.

WASHINGTON

NORTHPORT. To connect its lead mine with the Great Northern line at Northport or Boundary, a distance of 15 miles, the Electric Point Mining Co. may construct a railway costing \$200,000. The monthly haulage of 2500 tons costs \$5 per ton. Conditions at the mine are good. Roy Young is general manager.

TACOMA. Additions to the A. S. & R. smelter here include a 600-ft. stack, 51 ft. diam. at the base and 30 ft. at the top. The Denny Renton Clay & Coal Co. of Seattle secured the contract for over 2,500,000 acid-resisting vitrified brick for the chimney.

The tide-flat plant of the Bilroze Alloys Co. is to spend \$100,000 in additions, including four furnaces. The present plant consists of crusher, rolls, jigs, tables, and 3 electric furnaces, producing ferro-manganese, also concentrating and cleaning tungsten ores.

CANADA

BRITISH COLUMBIA

SILVERTON. The 100-ton mill of the Galena Farm mill has operated a year, according to the manager, P. W. Clark. The mill superintendent, G. A. King, states that the plant is saving 90% of the lead on the tables and 80% of the zinc by flotation. The lead concentrate has a content of 70% and 80 oz. of silver per ton, the zinc concentrate 47% of that metal and 20 oz. of silver. By installing more tables and flotation machines the capacity is to be raised to 125 or 150 tons daily. Crushing is done by rolls and Huntington mills. On account of water shortage treatment has been suspended until March. The feed delivered to the mill contains 12% lead and 18% zinc, according to John Bresnahan, the mine superintendent. These contents are fairly representative of the body which has an average width of 8 to 9 ft. The shoot has been followed by drift for 30 ft. at a depth of 100 ft. It is being mined through a tunnel that attains a depth of about 250 ft., where connection is made with the shaft.

ONTARIO

COBALT. During December the Nipissing company produced silver worth \$259,836 from 80 tons of rich ore and 6162 tons of low-grade ore. The refinery shipped 396,879 oz., partly custom metal. Development generally was favorable.

PORCUPINE. Enlarged and more economical operation will follow consolidation of the McIntyre, McIntyre Extension, and Jupiter mines, in charge of R. J. Ennis. The new aerial tram across Pearl lake is ready for ore at the rate of over 500 tons daily. A central hoisting shaft is to be arranged. On the 1000-ft. level the ore-shoot is from 20 to 40 ft. wide, assaying \$20 per ton. This has been opened for 550 feet.

MEXICO

In his annual address to shareholders of the Santa Gertrudis company in London, the chairman, F. W. Baker, said:

"It is a matter of the utmost regret to the directors to realize that, so far from conditions in Mexico having improved during 1916, the reverse is actually the case. The labor supply is not only insufficient, it is inefficient in quality—a fact that has not deterred the more turbulent members from a ceaseless agitation for higher pay, until we are now paying a higher wage than was the case previous to the present revolutionary period. The political outlook is still most uncertain, and even if such a discussion could be regarded as wise, or politic, I doubt if it is possible for any of us to attempt to forecast the future. With the exception of certain delays incidental to the irregular running of the railways, and of the difficulties above mentioned in connection with the labor supply, all of which we share in common with other concerns in Mexico, we have been free from many trials and troubles experienced by some other companies. For this the thanks of the shareholders are due, to a great extent, to the manager and his staff for tactful and able handling of many difficult situations."

HIDALGO

PACHUCA. The Santa Gertrudis company reports as follows for the year ended June 30, 1916:

The disturbed political situation continued to affect adversely the regularity and scale of operations. Work was confined to development and ore production. No important equipment was required. Labor and supplies were scarce and inadequate, but improved compared with the previous year. The currency situation required close attention to avoid losses, owing to the extreme and rapid fluctuations in the value of the peso. Development amounted to 14,865 ft. Water pumped averaged 875 gal. per minute. Reserves amount to 1,214,000 tons, containing 74,405 oz. gold and 14,881,090 oz. silver. Operation in 1916 varied from 20 to 79%, an average of 56.6%. The new mill treated 227,616 tons of ore, assaying \$8 per ton, with 92.85% recovery. A dividend of 24c. per share absorbed \$360,000.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

A. W. ALLEN is at New York.

W. H. LANAGAN was in New York recently.

WALTER STRACHE has returned to New York from Chile.

W. R. FELDTMANN has returned to London from West Africa.

EDGAR A. COLLINS is visiting the copper districts of Arizona.

R. P. LAWRENCE, manager for the Austral Bolivia tin mines, in Bolivia, is here.

ALBERT BURCH has returned from Butte and will proceed shortly to Colorado.

W. SHELLSHEAR, formerly at Broken Hill, has joined the staff of the Burma Corporation.

A. W. FREEMAN, of Sydney, Australia, was in San Francisco and is now on his way to New York.

W. C. ROBOTHAM has been appointed superintendent of the Banner mine, near Oroville, California.

ALGERNON DEL MAR passed through San Francisco on his way from eastern Oregon to Los Angeles.

H. W. GEPP, of the Amalgamated Zinc, Broken Hill, has arrived in Australia from the United States.

F. P. BURRALL of New York, who has been at Dawson during the past season, is wintering in the United States.

R. CLYDE CAMERON is general superintendent of the Primos Exploration Co.'s Copeland mine, near Boulder, Colorado.

G. G. THOMAS, former manager of the Dome Lake and Hudson Bay mines, in Ontario, has opened an office at Toronto.

SIDNEY J. JENNINGS was injured, fortunately not seriously, in a railway accident near Durango, Colorado, on January 21.

HUGH ROSE, manager of the Santa Gertrudis mine, Pachuca, Mexico, is in San Francisco, and is likely to make it his headquarters.

F. L. STACK, until recently with the Morochocha Mining Co., Peru, has changed his address to Fomento, province of Santa Clara, Cuba.

JAMES IRVING, of the Los Angeles firm of assayers bearing his name, has removed his laboratory to 702 South Spring street, Los Angeles.

WILLIAM MOTHERWELL has opened an office as consulting flotation engineer at Nelson, B. C., and at present is at the Blue Bell mine at Riondel.

CHARLES E. VAN BARNEVELD, supervising mining engineer and metallurgist to the U. S. Bureau of Mines, was here on his way from Salt Lake City to Tucson.

CARL J. TRAUERMAN, of Butte, Montana, is on a trip to Chicago, Pittsburg, and New York. He can be reached by addressing the A. I. M. E. headquarters, New York City.

MYRON L. FULLER, of the Associated Geological Engineers, read a paper entitled 'The Appalachian Oil Fields' at the meeting of the Geological Society of America of December 27-29.

G. S. RICE, of the U. S. Bureau of Mines, has been investigating the Crow's Nest Pass Coal Co.'s troubles in British Columbia, with W. FLEET ROBERTSON and THOMAS GRAHAM of the Provincial Department of Mines.

ELISHA W. SLATER, who for years, in the earlier days, had been a prominent mine manager and operator in Butte county, California, died at Oroville January 19 in his 89th year. His mining activities were mostly river and hydraulic work.

Forty-five men have enrolled in the 20th annual three-months' mining session at the College of Mines, UNIVERSITY OF WASHINGTON, Seattle. Their ages vary from 21 to 56 years, averaging 32 years. All but ten of the men have had mining experience. They register from all parts of the Pacific Coast, from Arizona to Alaska. Quartz miners are in the majority, but several placer miners are present, also a few coal men.

THE METAL MARKET

METAL PRICES

San Francisco, January 23.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	35
Pig lead, cents per pound.....	7.75—8.75
Platinum, soft and hard metal, per ounce.....	\$85—91
Quicksilver, per flask of 75 lb.....	\$80
Spelter, cents per pound.....	13
Tin, cents per pound.....	44
Zinc-dust, cents per pound.....	18

ORE PRICES

San Francisco, January 23.

Antimony, 50% metal, per unit.....	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	15.00
Magnesite, crude, per ton.....	6.50—9.00
Manganese, 50% (under 35% metal not desired).....	16.00
Tungsten, 60% WO ₃ , per unit.....	18.00—20.00

Magnesite is in moderate demand, there being inquiries for the high-grade iron-free mineral, and also for the iron-bearing mineral. These two varieties are used for wholly different purposes, and magnesite suitable for one use may be wholly unfitted for other uses.

Bulletin 111 of the U. S. Bureau of Mines, entitled 'Molybdenum: Its Ores and Their Concentration,' with a discussion on markets, prices, and uses, by Frederick W. Horton, should be secured by miners interested. Its price is 30 cents.

The concentrating plant at Renfrew, Ontario, is paying \$1.90 per lb. for concentrate containing 80% MoS₂. Penalties are imposed for copper and bismuth. Ore carrying from 2 to 3% MoS₂ receives \$14 per unit.

In time of peace Germany was the largest consumer of tungsten ore, and it is probable that when peace succeeds war Germany will again require a large amount of the ore. Although Great Britain has taken steps to reduce tungsten ores at home, she is unable to get the desired ore supply to keep the works employed, and the present outlook is that not only will the present price be maintained, but it is thought likely that it may be somewhat higher.

New York, January 19.

Antimony: This ore is scarce. For early delivery \$1.50 per unit has been offered but without success. Chinese and Japanese grades are firm at 14.25 to 14.50c., duty paid.

Tungsten: While it is stated that \$17 has been paid in this market, it is known that Eastern consumers have obtained ore for \$16 in the past few days. Both foreign and domestic consumers have bought.

EASTERN METAL MARKET

(By wire from New York.)

January 23.—Copper is firm but quiet. Lead is strong. Spelter remains quiet.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.	Average week ending
Jan. 17.....	75.00

PLATINUM

Price of platinum, New York, is \$90 per ounce for soft metal and \$96 for hard.

Eastern Metal Market

New York, January 17.

The metals presented a ragged aspect just prior to the appearance of the Entente Allies' reply to Germany, but the publication of the note relegating peace to the uncertain future stiffened all prices, caused concessions to be withdrawn, and put a stop to short selling.

The trade is in the dark with regard to what is going on at London because of the extent to which cables are delayed. None was received yesterday. The last information received indicated that copper and spelter were lower.

On January 9 and 10 a metal-selling house alleged to have German affiliations sold over 500 tons of January, February, and March spelter on the floor of the New York Metal Exchange at concessions, doing so openly, and inviting the presence of those who might buy. This may have been done because of a sincere belief that peace was near at hand, although it is suggested that the real purpose may have been the psychological effect on the trade at large, which seems a little far-fetched. Having sold the metal referred to, the seller made no further offerings. The exports of zinc are below what they should be to absorb their share of production.

Prompt lead is scarce and higher.

Tin has advanced, and is none too plentiful for early delivery.

Antimony is firm, and aluminum lower.

The iron and steel markets show a quieter tendency as to new business, although specifications against contracts are as heavy as ever. There is an enormous demand for standard low-phosphorus and Bessemer pig-iron, for both export and domestic consumption, the buyers being willing to contract for deliveries into 1918. Consumers of foundry-iron, on the other hand, are unwilling to contract into the last half at present prices. The railroad congestion appears to be a little relieved in the East, although unimproved in the Middle West. Canada is looming up as a large purchaser of steel products, as well as of machinery. She has about reached the limit of her steel-producing capacity. The Imperial Munitions Commission has placed an order for ten 8-ton Heroult electric furnaces for a plant to be built at Toronto. The Commission is building an arsenal at Lindsay, Ontario, which will consist of 60 buildings, on the construction of which 1400 men are now at work.

Deliveries of metal-working machinery are somewhat easier, especially those not classed as strictly standard.

COPPER

Prior to the publishing of the Entente Allies' reply to the German peace note the market sagged to an extent which was a cause of worry, but following the reply, which seemed to make peace more remote than ever, the market took a turn upward, and in the past two or three days it has been growing stronger. On Monday and Tuesday of this week (January 15 and 16) the market was a puzzle, inasmuch as bids were declined, sellers refused to make prices, and with it all there was no great desire to buy. Under the circumstances, all prices were rather nominal than otherwise. It was reported January 10 that some large foreign business was under negotiation, but the majority of the trade did not take the rumour seriously, knowing that it came from sources close to Wall Street, and probably represented an attempt to bolster up the stock market. At the same time, it was admitted that there might be some ground for the story. On that day March, April, and May electrolytic was offered at 26c., but failed to attract buyers. Even a large munitions maker, known to be looking for copper, could not be interested, as he believed that he could do better by waiting. Then came the Allies' note strengthen-

ing the entire market, and the quotations for the months referred to jumped to 27 to 27.25c., delivered in Naugatuck valley. The views of the munitions maker referred to underwent a change and he asked a renewal of the offer at 26c. But the views of sellers had changed also, and the munitions maker did not get the copper. Yesterday spot electrolytic was quoted at 29c., and some special Lake sold at 29.50c. Second quarter electrolytic was quoted yesterday at 27.50 to 28c. But little is available for the first quarter, and not a great deal for the second. Selling short has entirely ceased, and second-hands have withdrawn their concessions. The London market is difficult to understand, likewise the attitude of the British government. The quotations cabled on January 12 did not reach New York until January 15, and yesterday (January 16) no cables were received on any of the metals. They are undoubtedly being held up by the censor. The last cable received put electrolytic at £141, against £143 a week ago. The exports during the period from January 1 to 17 totaled 11,591 tons, which is not large.

ZINC

Unusual influences appear to have been at work in this metal. As stated a week ago, 120 tons, including January, February, and March deliveries, were sold on the Exchange, January 9, at a concession from the market price. On the following day 360 tons more was sold for the same deliveries, 120 tons of each, at prices representing a decline of $\frac{1}{4}$ c. from those of the preceding day. All of this selling was done openly by a house with alleged German affiliations. Delayed cables disclosed that the London market was weak on the day of sale under pressure to sell. No cable was received yesterday, but the last information to arrive put spot zinc at London at £45 10s., against £50 5s. a week previous. Altogether it seems certain that a world-wide effort to lower metal prices has been made. Following the Allies' note the market stiffened, with the result that spot prime Western was quoted yesterday at 10c., New York, and 9.75c., St. Louis. February was around 9.62 $\frac{1}{2}$ c., St. Louis, and March around 9.37 $\frac{1}{2}$ c. Second quarter was near 9c., St. Louis. The exports were light, amounting January 1 to 17, to 3133 tons. Authorities point out that the exports should be between 17,000 and 18,000 tons per month, if the large production is to be absorbed. Hopes of big buying by the Entente Allies, commensurate with their purchases of copper, continue to be entertained. A fair domestic business was done last Friday and Saturday, and Monday of this week, but yesterday (January 16) the market was quieter. Sheet zinc is unchanged at 21c., carload lots, f.o.b. mill, 8% off for cash.

LEAD

Transportation difficulties have been the cause of manufacturers running short of lead, and they have entered the market for spot supplies, only to encounter what appears to be a *bona fide* shortage. This, and the strength imparted by the more remote prospects of peace, have caused prices to advance. For January delivery, 7.65c., New York, and 7.50c., St. Louis, was asked by independent interests yesterday (January 16). The quotation of the leading interest, nominal inasmuch as it is only used as a basis for establishing an average price, was 7.50c., New York. Early last week the market was weak, substantial concessions being made on prompt. At this writing there is no pressure to sell, holders expecting a stronger market, while consumers are wary of buying because they have in mind the recent slumps that the market has endured. The exports, January 1 to 17, total only 330 tons. No cable was received yesterday, but the last price received from London left spot unchanged at £30 10s.

Manganese in 1916

Preliminary estimates by D. F. Hewett, of the U. S. Geological Survey, show that the production of manganese ore in 1916 was about 27,000 tons, the greatest since 1888 and nearly three times that in 1915, which was 9709 tons. The estimate does not include manganiferous-iron ores that contain less than 40% of manganese, but it is probable that the production of ores of this class also was much greater than in 1915. This output has come largely from seven States, and the order in production will probably prove to be as follows: California, Arkansas, Arizona, Georgia, Virginia, Utah, Colorado. This order is interesting, because this is the first year in which a Western State remote from the steel-producing centres has contributed the largest amount of manganese ore. The activity among manganese mines in California is due largely to the market for ores provided by the Noble Electric Steel Co. at Heroult. It is not yet possible to state the production of high-grade ores adapted for use in dry batteries, but reports indicate that it will exceed 2500 tons and therefore be five times that in 1915. Ores of this class are now produced in Arizona, California, Utah, Colorado, and Virginia, but the amount produced is still scarcely one-tenth the normal demand.

The prices paid for manganese ore adapted to the manufacture of ferro-manganese rose from a maximum of \$22.50 for 50% ore in 1915 to \$32.50 in March, 1916. Except for minor fluctuations, which depended on temporary variations in demand, prices were nearly constant until the last month of the year, when sales at prices as high as \$39 for 50% Indian ore were reported. There were rumors that a contract for the delivery of 200,000 tons of Brazilian ore during 1917 was placed at \$23 per ton f.o.b. Brazilian port, from which the freight rate to Baltimore is \$12 per ton. Ore adapted to the manufacture of dry batteries (containing 80% of manganese di-oxide and less than 1% of iron) continues to sell for about \$85 per ton.

Imports of manganese ore for the first ten months of 1916 amounted to 495,299 tons, of which 401,177 tons came from Brazil. For the same period of 1915 Brazil supplied 181,258 tons out of the total of 192,286 tons. There is a prospect, therefore, that the imports for the entire year will prove to have been almost double those of 1915—320,778 tons. Considering the small part of the demand that was supplied by Brazil during the eight years prior to 1914, it is re-assuring to know that the deposits of that country can be made to yield such enormous quantities of ore. Imports from India, Cuba, Panama, and Japan were also greater than in 1915.

Imports of ferro-manganese for the first 11 months of 1916 were 73,435 tons, which is nearly 50% more than for the corresponding period in 1915, though bearing a smaller ratio to the domestic production. Prices reached the highest figures ever recorded in the United States in April, 1916, when, it is reported, \$400 per ton was paid for a small lot for immediate delivery. For the remainder of the year the price declined steadily to \$160 per ton in October, then rose to \$175 again in December. The price of spiegeleisen carrying 20% of manganese ranged from a maximum of \$52 in July to \$40 in December.

An important consequence of the prevailing high prices of manganese alloys is the attempt on the part of steel-makers to use substitutes. The extent to which substitutes for manganese in steel may be used has not been determined, but experiments by several steel works show that an alloy of iron, carbon, and titanium may be satisfactorily used to replace a part of the ferro-manganese commonly added.

Although a number of mines in Virginia, Georgia, and Arkansas were re-opened during 1916, the greatest activity is reported among mines in California, Arizona, Utah, New Mexico, and other Western States. This is due in part to the operation of electric reduction plants in California and Washington, but

more largely to the low percentage of iron in some of the Western ores. Few Eastern mines that operate residual deposits can produce at a profit in large quantities ore that contains less than 1% of iron, and therefore most of the Eastern mines ship their product to Eastern furnaces to be reduced to ferro-manganese. The inaccessibility of most Western deposits makes it unprofitable to ship ore to Eastern makers of ferro-manganese, even at the high prices they are offering for manganese ore. On the other hand, many Western deposits are known and more have been discovered during recent years, which are capable of producing manganese ore with less than 1% of iron. At prevailing prices for such ores, they may be profitably shipped as far east as New York. There is a prospect at present that several Western mines may be able to ship high-grade ores to Eastern markets even when prices recede to the level of years prior to 1914.

Sulphuric Acid in 1916

The production of sulphuric acid in the United States in 1916 was much greater than in 1915. The estimated production of sulphuric acid of strengths of 50°, 60°, and 66° in 1916, expressed in terms of 50° acid, is 4,475,000 tons, an estimated increase over the production in 1915 of 600,000 tons, or more than 15%. The increase was distributed about equally between acids of strengths of 50° and 60°, as there was a small decrease in the production of acid of strength of 66°. The most notable feature in the sulphuric acid industry was the enormous increase in the production of acids of strengths greater than 66°. The estimate shows a production of these stronger acids of over 1,000,000 tons as against a production of less than 200,000 tons in 1915. It is not feasible to express the amount of these higher acids in terms of 50° acid; therefore the total given for them is in addition to the total given for acids of strengths of 66° or less. The estimated output of acids of strengths of 60° and 66° includes by-product acid produced at copper and zinc smelters. The output of acid so produced in 1916, expressed as 60° acid, amounted to nearly 950,000 tons, or practically the same as in 1915. However, over 110,000 tons of acid of higher strengths was produced at these smelters, a quantity nearly double that produced in 1915.

The market conditions throughout the country are reported to have been on the whole better than in 1915, and the value of the product will probably be somewhat higher than it was even during that year of high prices.

The estimates are based on returns received by Philip S. Smith.

The U. S. Bureau of Mines, has just issued Bulletin 111, 'Molybdenum, Its Ores and Their Concentration, with a Discussion of Markets, Prices, and Uses.' The author is Frederick W. Horton. The Bureau has been obliged to affix a price of 30 cents on this useful publication.

PIG-IRON PRODUCTION of Canada during 1916 is estimated at 1,046,185 tons. The steel output was 1,270,969 tons. These are increases of 28% and 42%, respectively. Electric furnaces made 39,098 tons of steel castings and ingots, against 61 tons in 1915.

CHROMIC-IRON ORE production of the United States in 1916 was over 35,000 tons, against 3281 tons in 1915. Most of this was from California—Oregon, Maryland, and Wyoming contributing. Imported ore averaged \$12.66 per ton.

COAL PRODUCTION of the United States in 1916 was 597,500,000 tons, an increase of 14%.

COKE MADE in the United States in 1916 was 54,300,000 tons, an increase of 30%.

EDITORIAL

T. A. RICKARD, Editor

WE are glad to say that the Randall rider to the Post-Office Appropriation Bill was defeated in the House of Representatives. This rider provided for a change in postal rates under a zone system like the one now applying to parcel-post matter. We discussed it in our last issue.

ON another page we publish an interesting letter on Chinese antimony, by Mr. K. C. Li, of the Wah Chang Mining & Smelting Co., the well-known dealers in Chinese antimony. We understand that the Canadian munition-makers have purchased a good deal of antimony on the New York market, and that the shortage of stock is favorable to the producer.

NO excuse, except improvidence, exists for the fact that the precious-metal mining industry should be crippled by the scarcity of cyanide. Why should we depend upon Germany or Glasgow for our supply of this necessary chemical when it can be made in unlimited quantity in the United States? We are paying \$1.10 per pound while the mines in South Africa get all the cyanide they require for 18 cents per pound. We have ample water-power, a supply of potash salts exists in the Searles and Owens lakes, and plenty of sodium can be obtained from the waters of Salt Lake, not to mention the salt measures of New York and Michigan. Another example of unpreparedness.

FROM time to time we receive letters or calls from investigators of metallurgical processes, notably flotation. It is remarkable how many of them go to work enthusiastically and energetically to discover something new without having taken the pains to acquaint themselves with what has been done already in the particular branch of research to which they are devoting themselves. All sorts of men are playing with flotation without having read the technology of the subject and without any notion of the extent to which their ideas may have been anticipated by others, as recorded both in the technical press and in the records of the patent-office. Such procedure is not only unscientific, but unprofitable.

IN the *Daily Metal Reporter* we find timely advice and warning to the metal-producing industry in this country. Our contemporary lays stress on the fact that the Allied governments are unwilling to enter into new commitments on terms increasingly onerous, so that the purchase of metals is being curtailed. Moreover, the contraction of cargo-space and of facilities for shipping

is decreasing deliveries to a serious degree. These are some of the reasons for stimulating the hope of peace. "Peace is very speedily becoming a bull argument," says the *Metal Reporter*. It looks as if the United States had obtained most of the prosperity incidental to the War and as if the humanitarian argument might now be strengthened by the enlightened selfishness prompted by economic facts.

WHAT comment is made on mining in the columns of the San Francisco press is usually sophomoric in style and substance. We read that a certain discovery of ore, quite fabulous, is "certainly of vast importance as bearing upon the truth, so often expressed in these columns, that the mineral wealth of California is as varied as it is unlimited, and that, despite the enormous quantities of ore already developed, we have as yet but scratched the surface of our metallic resources." These bromidic remarks will do nothing to enhance California's reputation as a mineral region, but we are willing to believe that they, and others like them, have often appeared in the columns of the *Morning Howl*.

THIS is not a political paper, it is a technical periodical, yet it is hard not to say something occasionally about the greater affairs of life. The suggestion is made in the *New Republic*—and it is a suggestion that many of us have discussed before now—to ask Congress to appropriate at least a hundred million dollars for the relief of non-combatants in the countries devastated by the war in Europe. At the same time an American commission should be created to strengthen the hands of the Americans doing the work of relief in Belgium, France, and elsewhere, thereby giving them some official standing. For this nation to give \$100,000,000 for such a purpose would not be too much—nothing like too much—having regard to our wonderful gain in wealth since the War began. Moreover, such an act would strengthen the President's position as a peace-maker.

PUBLIC improvement in the Central American republics is generally undertaken and financed by American, English, German, or French capital, but occasionally the wealthy native engages in these enterprises on his own account. It is interesting therefore to note, in the December bulletin of the Pan-American Union, that a number of capitalists at Juticalpa, which is the metropolis of the Department of Olancha, Honduras, have organized a company to dredge the Patuca river, with a view to making it navigable for ocean-going

vessels. This is the largest river in Honduras and rises among high mountains near the centre of the country. The streams that unite to form the Patuca—notably the Guayape—have long been credited with a fabulous production of gold and they flow through great forests of valuable timber, including mahogany, rubber, and Spanish cedar, but unfortunately the river is not navigable for sea-going craft, nor can it ever be made so. It is full of dangerous snags, the current is swift, and the difference between the low stage of water and that of flood-time is not less than 25 feet. The scheme is impracticable, and this may explain why foreign capital is not interested in the proposed improvement. If the interior of Honduras could be reached easily—by a railroad, for instance—it would do much to bring into prominence the mineral resources of the region; these are not without promise, but under existing conditions they have no economic value.

ON another page we publish a short description of the Bunker Hill smelter, now in course of erection at Kellogg, Idaho. To Mr. Jules Labarthe, the designer, we are indebted for this sketch of the plant. It will be noted that the double-roasting system is to be applied on a part of the charge. Pre-roasting is necessary only on material high in sulphur, to obviate the formation of too much lead matte. The ore of the Bunker Hill & Sullivan mines contains only a trace of copper and is comparatively low in sulphur on account of the iron content being in the form of a carbonate, instead of a sulphide. At the Northport smelter the copper that formerly was lost is now being recovered by re-concentrating the copper in the lead matte until the proportion rises to 18 or 20%. The copper-lead matte is roasted, to be melted subsequently with silicious ore so as to make a lead bullion and a copper matte, the latter containing less than 8% lead, while the copper averages 40%. Of the lead in this matte about 60 to 70% is recovered as dust and sublimate in a bag-house or a Cottrell plant. In lead smelting it is essential to separate the by-products in marketable form. We note that in the Bunker Hill smelter the softening-furnaces serve to remove the copper, as dross, from the lead bullion; this dross is returned to the blast-furnace, where the lead is recovered as bullion and the copper as matte.

Cyanide

This chemical product is becoming more scarce every day. In small quantity it has been bought recently for \$1.10 to \$1.15 per pound, but only odd lots are available. Before the War the supply of cyanide required by American mills came mainly from Germany or Glasgow. The one source is sealed by the blockade and 4000 tons is said to be held at sundry European ports. The Scottish output has been commandeered for British use in South Africa, India, and Australia. Most of the cyanide consumed in this country used to be imported, the importation of the raw and the finished product respectively depending upon the incidence of the duty, as

changed from time to time. Formerly the one American manufacturer, Roessler & Hasslacher, made cyanide on a scale nearly proportioned to the consumption in the United States, but their capacity to manufacture was not expanded sufficiently to keep pace with the increasing demand. This was due largely to the expectation in 1912, and before, that the tariff on cyanide would be lifted—as became a fact in 1913, when cyanide was put on the free list. Thereafter the idea of enlarging the domestic plant was set aside, it having become possible, on account of the cost of labor, to import the material more cheaply from Europe than to make it in the United States. However, even after cyanide went on the free list, the American manufactory of Roessler & Hasslacher, at Perth Amboy, continued to make some cyanide, but not much, until the conditions created by the War—the blockade of German ports—caused a scarcity; whereupon an earnest effort was made to augment the domestic output. This would have sufficed to meet the new conditions if unfortunately, last year, the Canadian government had not placed an embargo on the use of hydro-electric power generated on the Canadian side of Niagara Falls—a step taken because the firm of Roessler & Hasslacher was put on the British 'black list.' Since then the firm has hastened to enlarge its factory at Perth Amboy and to start a new plant for the manufacture of sodium in Virginia. The cyanide now in general use in the United States has sodium as a base; this used to come from Niagara Falls. Metallic sodium is used with cyanamide, which is made by fixation of atmospheric nitrogen electrically or from coke-oven and gas-oven by-products—anything that contains ammonia. Incidentally, the use of sodium sulphide for the sulphidation of oxidized copper ores, preparatory to flotation, is likely to make further demands on the sodium output of the country. It is also necessary to mention the fact that the citrus belt of southern California annually consumes 1800 tons of cyanide for the fumigation of the orange groves, to kill an insect pest, and any failure to do so would be likely to injure the orange crop for five years.

Evidently the position is serious. Some relief is promised next September or October, when the new manufactories of cyanide will begin to produce, but the shortage is already so acute as to compel the closing of many mills, treating gold and silver ores, and to cause great loss to an important industry. Our readers are urged to bring the matter to the notice of their representatives in Congress. The bill recently passed at Washington to authorize the power-plants at Niagara to draw more water from the falls, and so to facilitate the manufacture of more sodium, was hastened through pressure brought to bear by Western mine-operators. Another obvious action is to try and obtain immediate relief by persuading the Administration to secure the release of the 4000 tons of cyanide now held in Europe. As an act of war, it is reasonable for the British government to prevent the shipment from escaping, but the injury done to the German manufacturer is much less than that done to the American consumer and an arrangement could be

made whereby the purchase price was paid to, and held by, the American government until the close of the War. Immediate action is imperative.

Teachers and Wild-Cats

Somebody has sent us a copy of *The Arizona Teacher*, a magazine published by the Arizona State Teachers Association and circulating therefore chiefly among those that instruct the young idea how to shoot otherwise than with a 'gun.' In this magazine we find an article on 'Mining Investments,' written by Mr. G. M. Butler, Dean of the School of Mines in the University of Arizona. The circumstances provoke our interest. Here is a professor of mining giving advice to people whom we, for instance, do not reach, and yet they are just the kind of seriously minded people that are likely to be drawn by the lure of the wild-cat. Of course, the word 'investments' in the title is used in the ordinary and incorrect sense. Mr. Butler speaks of advertisements offering cheap mining stock and of those "tempted to invest hard-earned savings in such ventures." The word 'invest' is wholly out of place in such a context unless we assume that the intent governs the meaning of the term and that if a school-teacher puts \$100 into one of George Graham Rice's humbugs, believing it to be gilt-edged, it becomes an 'investment' to him—to the school-teacher. To Rice, of course, it is an 'investment.' However, Mr. Butler does not proceed far with his admonitions before he also discriminates between 'speculation' and 'investment,' the gist of his useful advice being the need for distinguishing between the use of spare cash in a mining speculation and the risking of a worker's wages in a gamble. As he says, it is well to distrust anyone that offers an "absolutely safe investment" in mining stocks. In times of boom the old phrases re-appear like the rub-bish that a big storm flings high on the beach. The use of such terms as 'manufacturing proposition,' 'industrial enterprise,' 'gilt-edged investment,' and the like, when applied to a prospective mine, commonly indicates either the intention to swindle or else gross ignorance, for those that know anything about mining know well enough that risk is essential to a business in which great gain is promised—and often won. Mr. Butler tells the teacher that the purchase of mining stock about which he knows nothing may enable him, "to make more money than from years of work," but he warns him that he must have his eyes open and realize the essential risk—in short, he might as well put his money on the red or black, on the little horses, or on the turn of a card. School-teachers are not supposed to do that, because those addicted to such excitements are unfit for the serious work of instructing youth. However, on another page of the same magazine we find an advertisement offering stock in the Arizona Ray, and an appeal is made expressly to the dominies, for it is stated that "a certain teacher in Prescott has cleaned up enough money on Little Daisy to take his family and has been studying a year at Columbia University in New York. Another

teacher in Jerome has cleaned up about \$30,000.00 this year in copper stocks and is getting an income of about \$300.00 per month. We know of dozens of cases of a similar nature." This is signed—by whom would you suppose—by the "Editor." At the bottom of the page it is written: "Support the Advertisers Who Support Us." Here's a pretty kettle of fish! Who is the 'Editor'? He wields English clumsily, if one is to judge from the first sentence in the note and he employs ciphers recklessly, for the .00 after the two sums mentioned serves only to magnify the amount deceptively. Is this 'Editor' the editor of *The Arizona Teacher*? If he is, then his diction is as faulty as his judgment, for the sensible article by Mr. Butler on one page does not harmonize with the flamboyant advertisement of a 'wild-cat' on another page. Whether this particular 'wild-cat' be a comparatively domesticated specimen of the genus or a fierce and bewhiskered member of an omnivorous—not carnivorous—tribe, we do not know. The quotation reproduced from a report by an E. M. is not convincing, to put it mildly, for the kind of orebodies exploited in the Ray district cannot be described correctly as "ore beds" and the contiguity to the Ray Consolidated mine is an argument that an experienced mining engineer would be slow to use, having regard to the fact that all this outlying ground must have been carefully valued by the neighboring companies. It may be a reasonable risk and a sensible venture, but it is exactly the sort of thing that Mr. Butler warns the teachers not to touch except as a straight gamble. "Buy Arizona Ray at 30c. per share before big advance" says the advertisement. Nothing is said about the capitalization; 30c. may represent a valuation for this prospect that even the finding of rich ore will not justify. The 'editor' would be better employed in ascertaining and explaining such essential items of information than in retailing stories about venturesome teachers who played a game that they did not understand. The advertisers of Arizona Ray ought to have taken care to ensure that their efforts to reach the pockets of the school-teachers were not marred by the coincident publication of such a warning as Mr. Butler's. Returning to that article, we find that he advises his readers not to consider any property "unless a competent mining engineer has reported favorably upon it." Again he makes a mistaken use of the term "small investor," meaning petty speculator. He refers to reports by pseudo-engineers, who write about "dikes of limestone" and "flows of chert." But school-teachers are unlikely to know a good report from a bad one, so he gives the excellent advice that teachers should ask a mining engineer to pass upon the prospectus or report before they make a purchase of stock. That advice is good for others besides school-teachers. It is remarkable how rarely the public avails itself of this simple precaution. The advice may well be taken by bankers and merchants also, many of whom will use large sums of money without even taking this preliminary measure of caution. As a conclusion to his remarks Mr. Butler suggests that the teachers should either grubstake prospectors or form

a small syndicate to acquire promising prospects. He suggests subscriptions of \$25 to \$50 per month as sufficient for the purpose and refers to a small group of Missouri Valley teachers that cleared \$200,000 in a few years at a cost of \$10 per month and to a group of Denver lawyers that "made millions in this way through operations in Creede and Cripple Creek." The lawyers can take care of themselves, but the teachers cannot. We fear that the article, which starts by warning simple-minded and earnest persons against wild-cats, ends by advising them to go 'wild-catting,' using this term in its less opprobrious sense of a risky venture in undeveloped claims. We can write an article on the participation of school-teachers in mining speculation in one word: Don't.

The Miami Appeal

On another page we reproduce part of the brief for the Miami Copper Company before the U. S. Circuit Court of Appeals at Philadelphia against the judgment given in favor of Minerals Separation Ltd. by the District Court of Delaware on September 30, 1916. It will be seen, as we anticipated, that counsel uses the Supreme Court's decision in the Hyde case as an argument against the charge that the process of patent 835,120 is being infringed by the Miami. The Supreme Court's severe definition of the so-called agitation-froth process of Minerals Separation enables counsel to show that the pneumatic or Callow method is of a different kind. Beyond economy in the use of oil, as practised by every millman, there is not much in common. And in regard to the so-called critical proportion of oil—less than 1%—we repeat here that the supposition of Minerals Separation that more than 1% of oil prevented flotation was based upon experiments on Broken Hill ore with the use of a heavy oil—oleic acid. If too much of that particular oil—not now used in the United States—was employed, it tended to coagulate the metallic particles into granules, which sank to the bottom of the cell, spoiling the operation. Again, the particularly coherent, persistent, and otherwise remarkable froth, to which the Minerals Separation people made claim, was due undoubtedly to the thick kind of oil that they used as a modifying agent. We know now that the character and quantity of the froth are readily affected by the choice of the contaminant that lowers the surface tension of the water so as to make the bubbles sufficiently long-lived to perform their metallurgic function of buoying the mineral particles and carrying them over the lip of the flotation-cell. Agitation also is a factor, insofar as it determines the quantity of air admitted into the pulp and the degree of emulsification. The Supreme Court decision lays stress on the proportion of oil, the stability of the froth, and the character of the agitation, no one of which, we believe, is essential to the success of the flotation process generally, however necessary to the method described in patent 835,120.

Another interesting feature of the brief is the discus-

sion of the soluble frothing agent of patent No. 962,678. It will be remembered that the lower court decided that Miami had infringed this patent also, by reason of using cresol with pine-oil. During the trial of the case it was acknowledged by Minerals Separation that the methods described in 835,120 and 962,678 were alike; it was also conceded that the claims of both patents call for vigorous agitation, which the Supreme Court has interpreted to mean such agitation as will beat the necessary air into the pulp. It is argued now that the use of tar and tar-products as specified in No. 793,808, the perforated-coil patent, invalidates No. 962,678. Moreover, it is a matter of record that Haynes, in his patent of 1860, mentions the use of coal-tar from gas-works and refers separately to insoluble substances such as "oleaginous matters." Coal-tar is soluble to the extent of about 20%, and indeed all the flotation-oils are variously soluble. The grant of a patent for a soluble frothing-agent shows to what an absurdity patents can be reduced. Cattermole, Sulman, and Picard described the use of phenol and cresol, two soluble agents, in patent No. 788,247. Neither in that patent nor in 962,678 is the proportion of the frothing agent specified, and it has been admitted by the Minerals Separation experts that any amount of the soluble modifying agent is effective to produce the desired result. In the light of the Supreme Court's decision on patent 835,120 and the emphasis placed therein upon a 'critical' proportion of oil, it may be that the vagueness of patent 962,678 will prove a final bar to validity. We hope it may, for immunity from patent monopoly will stimulate the many efforts now being made to use modifying agents other than oil and to develop the flotation process to further efficiency. If any one company, particularly the one that has tried persistently to prevent the spread of technical information on the subject, is to control productive research, it is unlikely that fruitful investigations will be multiplied. The flotation process is the product of the work done by a hundred men, not two or three industrious patentees. Any accurate apportioning of credit and of reward is impracticable, and it remains for all to do their work in the scientific spirit, which aims to achieve results, not to tax the application of them.

The Minerals Separation people are following the bad example of the cyanide patentees, in standing astride the mining industry with a club. Those who recall the first applications of cyanidation on the Rand will remember that the principal mining companies, led by the management of the Robinson mine, were ready to pay something like 2½% royalty on the gold extracted by cyanidation, but the patentees wanted 7%. Against this exaction the mining companies decided to fight, and they fought successfully, so that the South African mines never paid any tax on the use of the cyanide process.

By the way, we shall be glad to give equal space and publicity to the brief of Minerals Separation in the appeal at Philadelphia if a copy of the text is sent to us either by the company or by one of its friends.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

A Flotation Testing-Machine

The Editor:

Sir—You showed an illustration of a Callow testing-cylinder in an article some time ago. I enclose a sketch

of a method I have used for making the bottom of such a cylinder.

ALFRED T. FRY.

Broken Hill, N. S. W., November 25.

The Prevention of Misfires

The Editor:

Sir—The kindly criticism on my recent article by Mr. Edward Higgins and Mr. W. S. Weeks is duly appreciated. As I differ somewhat from the above gentlemen, and to some extent with the quotations cited by them from U. S. Bureau of Mines, also as one or two of my suggestions seem to have been misunderstood, I deem it only proper to make my position clear, prefacing my remarks by saying that the suggestions in this and my original article are based upon close observation and practical experience covering many years, and at many times having a direct financial interest in the results obtained from the use of explosives. As to the danger of a misfire through bending of fuse, as Mr. Higgins says, more than 40°, or in any event over 180°, as is the case in the method mentioned, it would seem that the diameter of the bend should be taken into consideration, as it is bent

360° in the original coil without injury, and with good fuse, in proper condition, it may be tied in knots, and will not crack or miss.

The method I prefer in making primers is to punch a diagonal hole in the powder near the end of the cartridge, insert the cap, and bend the fuse across the end of the powder, and insert in the hole, cap-end first. This leaves a chance to press the powder firmly into the drill-hole without disturbing the cap. While a wooden punch is desirable, and should be employed, it is seldom that it is used, it being an almost universal custom to use the pointed end of a candlestick for the purpose and while this looks careless, I do not remember ever having heard of an accident from this cause.

As to tying paper around the fuse with a string, as suggested, it is quite likely that in most instances it would be neglected, though quite necessary, if primers are to be made in the manner suggested by Mr. Higgins. When made after my method there is no need of tying. Another advantage of this method is that when loading 'uppers,' as in a raise or stope, the powder may be pressed firmly, so as to fill the hole, thus holding it in place. Another stick of powder is placed on top of the primer and pressed so as to fill the hole, completing the operation. As to the use of tamping in 'uppers,' even if it were desirable, it is generally out of the question, as there is seldom at hand any suitable material for the purpose, although sometimes a small piece of wet burlap is used to assist in keeping the powder in the hole.

As to Mr. Weeks's suggestion that in case sufficient resistance were offered by the air, 'bulldozing' would be a most efficient method, I submit that under the conditions to which this method of blasting is adapted, it is quite efficient. I can hardly believe Mr. Weeks would suggest bulldozing in the face of a drift, when the rock had no chance to break, except toward the powder. This method is quite efficient when applied to detached rock, or boulders, and its efficiency is due to the resistance offered by the air to the explosion. It requires the use of more powder than when holes are drilled, for the reason that the energy of the powder is exerted against the rock in one direction only, whereas when confined in a hole its force is exerted in all directions.

In this method there is generally much more powder used than is required. I have seen men on construction work, and on highways, etc., in order to remove a stump, dig a hole under it and then use a 50-lb. box of powder. Needless to say, the stump was removed. It is also true that less than one-fourth the amount of powder would have accomplished the same result.

In the quotation from the Bureau of Mines publication, while stating that the use of the most efficient stemming materials may increase the useful energy of the shot 93%, it is not stated that this refers to nitro-explosives, though such is inferred. If so, it is quite contrary to my experience; anyway, it is likely that the experiments were conducted under conditions quite different from those encountered in actual mining practice, and even though the useful energy should be somewhat increased, this advantage would be more than offset by the chance of having a miss from causes I have mentioned.

Lastly, contrary to Mr. Weeks's impression, I do not favor placing the primer in the bottom of the hole, neither do I place it in the top, but, as stated, in the second stick from the top and cap-end *down*, as it is not desirable to have the cap too near the collar of the hole, thus increasing the chances of its being pulled out by tearing away of a portion of the hole by another shot, or of the fuse being caught by a flying piece of rock.

As to misfires being caused by bending the fuse while cold, or using damp fuse, this is readily admitted, though the blame for using damp fuse is on the management for not having it stored in a suitable place. A miner has no choice but to use what is furnished him.

E. F. BROOKS.

El Dorado, California, January 10.

The Editor:

Sir—Just an additional word on this important subject. I have found that there is a decided advantage in placing cartridges of nitro-powder in drill-holes if the paper envelope be slit in two or three places with a knife longitudinally of the cartridge before inserting it in the hole. This permits the soft yielding powder to spread out, completely filling the cross-section of the hole when the charge is pressed firmly forward with the tamping stick—not the iron spoon—and the powder then remains where it has been placed. This scheme is particularly useful in charging 'uppers.' In some mines suitable material for tamping is not easily available underground, and miners usually take a can or box of loam, or clay, or some sort of earth, into the mine with them to be used in tamping holes, and particularly uppers. I note what Mr. E. F. Brooks has said concerning the charging of holes without tamping, and while I agree with him that tamping is not of vital importance, yet miners have become so accustomed to tamping all holes, that many of them look upon charging a hole without tamping as a foolish waste of time and material; so tamping will probably continue to be the fashion for some time to come.

Bulldozing is resorted to, both on the surface and underground, to break large boulders, and is generally done by sensible miners without any cover whatever, unless it be just enough soft dirt packed around the powder to keep it from rolling off the rock from a gust of wind, or from the concussion of another shot near-by, but of all the foolish and dangerous practices to which many miners resort the worst is that of piling on the powder a

lot of small rocks, from fine stuff to pieces as big as a man's first. When this is done the rocks fly in all directions and no one within a quarter of a mile is safe. I have knowledge of one instance where the manager of a large mine was hit on the leg by a piece of rock flying from a bulldozing shot, fired in a glory-hole, and that had been fixed in this insane manner. He was fully 600 ft. away at the time. He never completely recovered from the injury, and yet, the practice of covering bulldozing shots with loose rock continued at that mine.

Barstow, California, January 20.

MINER.

Effects of Faults

The Editor:

Sir—In the discussion columns of your issue of December 23, 1916, under the heading 'Effects of Faults on Richness of Ore,' Enquirer observes that in most instances under his notice where a vein or orebody is intersected by a fault, the continuation of the ore beneath the plane of dislocation is of lower value than that above the fault.

This is a condition which I have often observed, especially in veins carrying copper, gold, or silver. While it is dangerous to generalize too broadly in mining geology, I am convinced that in most of the deposits of this nature which I have studied the explanation lies in the fact that above the fault intersection the ore in the veins has undergone secondary enrichment by cold descending solutions. The mineral-bearing solutions upon encountering the fault would be diverted from the vein to the fault-zone, which is often more permeable than the vein itself. Thus, the process of secondary enrichment is confined to that portion of the vein above its intersection with the fault. This conclusion is supported by the frequent existence of sulphides and oxidized minerals above the fault, below which the ore changes abruptly in character, and consists of the primary minerals. I have observed this most commonly in copper deposits, but secondary enrichment also plays an important part in gold, silver, and zinc deposits. Galena veins are seldom enriched to any marked degree, most of the galena being primary.

The decided enrichment in the vein or orebody just above the fault-plane, noted by your correspondent, is a phenomenon which, I think, many of us have observed, and it may be explained by the fact that such an intersection of two fissures is an especially favorable place for ore deposition. The descending solutions from the upper part of the vein may be 'ponded' there temporarily, and in copper, gold, and silver deposits exceptional enrichment may result at such places. Moreover, these descending solutions may encounter other solutions ascending along the fault-zone, and precipitation of rich ore minerals may result.

Often secondary minerals are found in the portion of the vein below the fault intersection, but generally in smaller amount than above. In such cases they have usually been introduced before faulting occurred, and subsequent enrichment would be confined to the upper

portion of the vein above the fault. On the other hand, the existence of a fault across the vein does not necessarily imply a decrease in the value of the ore below the fault intersection, for it is not unusual for the value of the ore to continue unchanged, especially if conditions are unfavorable to secondary enrichment.

Every mine has its own peculiar geological problems, and I would not infer that the above explanation will cover every case, but I believe it will apply in many instances under the conditions stated.

Moscow, Idaho, January 10.

Some Pertinent Questions

The Editor:

Sir—In your issue of January 13 I notice a list of important questions under the heading of 'Some Pertinent Questions.' I must agree with the author that few superintendents can answer these questions off-hand, even in regard to the mine they are operating.

It is impossible to answer the first three questions without first taking into consideration the kind of rock you have to deal with. I have been in some mines where the rock varied to such a marked degree that what was considered a good shift's work in one place would not be considered so in another. I have in mind some of the mines in the Cripple Creek district and also in Leadville. The same will also apply to some of the mines on the Mother Lode here in California. There are places in the same mine where a good man working single-handed would not drill over four feet in an eight-hour shift, while in other places in the same mine a miner could drill nine to twelve feet and more, in the same time.

Answering the fourth question, it depends upon whether the rock breaks fine or coarse, for when it breaks moderately coarse and has sharp corners that catch and hang to the shovel, it is much slower to shovel than where it breaks fine. In shoveling from a rocky bottom, all one can use is the round-pointed shovel, whereas, if from a properly placed wooden plat, and very few of them are so placed, the shoveler can use a mine-scoop. I have found that while the steel plat costs more to install, it is by far the cheapest in the long run.

I should say that the steel plat with the square-pointed mine-scoop is 100% ahead of the rock-floor and the pointed shovel.

The seventh question cannot be answered without taking into consideration the nature of the ground through which you are driving. In many cases it is perfectly safe to drive 20 ft. or more ahead of the last set, while I have been in ground where I had a hard time holding it with 4-ft. sets and driving the lagging ahead. This is a question that has to be determined as the work progresses.

As to the best angle on which to drive an incline that is to be used to pass ore by gravity, my experience has shown me that the angle varies with the kind of rock. One ore will pass safely over one angle that will be either too flat or too steep for another ore. This is also a ques-

tion that has to be determined by actual experiment, on the ground.

As to the number of cubic feet of quartz in place required to weigh a ton, this will depend to a certain degree upon how well it is mineralized and also the amount of moisture in it. Some quartz it is safe to allow 17 ft. when broken, and others not over 13 or 14 feet.

I do not think any man should be required to spend over eight hours working underground. I have been in mines that worked eight hours and also those that worked ten hours, and my experience has shown me that the miners will do about as much in eight as they will in ten. I have found that the man that did not do a good shift's work in eight hours, did not do so in ten. I have found that a good miner is more efficient, month in and month out, if he works eight hours than he is if he has to work ten.

The bonus system is good for some kinds of work, such as drilling and shoveling. One has first to determine what a good shift's work is, then use that as a basis to work from, giving a bonus for all over that, as it acts as an incentive for the men to work harder and more intelligently, therefore accomplishing more at very little added expense.

I am not at all in favor of the contract system in any kind of mining, as I find that with efficient management, the men can be made to do just as much work on company time. There is a system in vogue in many mines of contracting the development work and I cannot see the economy of it when they keep the shift-bosses, foreman, and superintendent to look after the company work. If the contractor can get more out of his men, then I should be in favor of making him either foreman or superintendent of the mine and save the company's money. I have found that by far the greater part of the contractors have to be watched closely or they will slight the work in their favor, and it takes no more time to attend to the work on company time than it does to watch the contractors.

ARTHUR W. STEVENS.

Piedmont, California, January 15.

The Editor:

Sir—I have carefully studied the A B C questions stated in your issue of January 13, and am forced to admit that I pass—or rather—fail. I might have been able to answer some of them when I used to sign my name with the E.M. attachment, but I have even forgotten now whether I ever could have answered most of them. If you continue the list, please stop along about L M N, because there will surely be considerable embarrassment felt throughout the profession by that time—and as for the X Y Z, there would be no one left in the class, except possibly a few mining professors.

It may be that there are two classes of superintendents, one with hats larger and the other with hats smaller than 7. So that there may be hope for the majority; let me state that mine is under. The lack of available room may explain my ignorance, but it has always seemed to

me that the mind which contained numerous figures and other data was not a mind capable of invention or originality in meeting the numerous emergency problems that confront the mine superintendent, especially of a small property. "Necessity is the mother of invention"; therefore the man who doesn't have the figures in his head is under the necessity to produce the invention; and the constant exercise of invention, even in small ways, must develop greater originality. The result is that each problem is met by a solution which is especially applicable to it, and while an extra amount of time may be consumed in doing it, the ultimate efficiency more than compensates. In organizing a new mining property, in opening up a new stope, or in breaking-in green men, there is no benefit in knowing the costs attained elsewhere; the problem rather is to cut and fit the available forces to suit the unchangeable conditions. The best possible results in any particular case may be far below or perhaps far above the average recorded results elsewhere. Even after everything has apparently been considered and figured out, there will be frequent changes necessary, or else the whole system will revert to chaos. I would like to hear from some of the 'above 7's' as to whether they consider that their originality and invention is impaired by carrying around an unlimited number of facts and figures.

ALFRED STRONG LEWIS.

Phoenix, Arizona, January 15.

Chinese Antimony

The Editor:

Sir—It may interest you to know the conditions affecting the antimony market in China, which is, as you know, the chief source of supply for the world.

The sensational fall in the price of antimony which took place on the New York market during the summer months of this year and which was due to causes that I need not mention here, has had as an immediate effect the curtailing of the mining output, as well as of the smelting capacities of the works of the chief producers in China. This was followed by the gradual shutting-down of a great many small mines that were hastily opened up at the time of the boom in price, and the small smelting works that depended on the supply from such mines have naturally had to suspend operations. Moreover, the tremendous speculations that took place among the Chinese merchants have caused them tremendous losses and reduced some of them from a prospective millionaire condition to a state of bankruptcy. Of course, the large producers have been able to stand the test, for the reason that they have accumulated large profits and depend mostly for the supply of raw material on their own mines.

The situation at present seems, in my opinion, to have undergone a decided change for the better. In the first place the large stocks that existed during the early summer months in Shanghai, Hankow, and Changsha have gradually disappeared and so far as I know have not

been replenished. Some of the Chinese speculators have dropped out of the market entirely, either on account of having losses or through the difficulty in getting the metal from the small sources that sprang up during the time of the boom in price.

Looking to the present position, we have to reckon with two important factors that exercise a very strong effect on the antimony prices likely to rule for some time to come:

In the first place, there is a tremendous rise in freight both to Europe and America. Prior to the War the freight on antimony from China to New York was only 25s. per ton, whereas at the present time the freight is 90s. per ton, with every prospect of it being raised again as the shipping conditions become more and more acute.

In addition to this there is a tremendous war-risk premium on shipments from the Far East that was practically eliminated prior to the War.

In the second place, we have to reckon, and to a very great extent, with the abnormal rise in the price of silver. This rise, which is almost unprecedented, has already seriously affected exports from China and commodities that are unable to secure a higher price through competition from other quarters are lying idle in the godowns of Shanghai.

The Chinese smelter reckons his profit in Chinese currency, that is, in taels, and if the exchange for remitting money from abroad to China is unfavorable, he is bound to raise the price for his commodity, otherwise he might make a dead loss on the transaction.

It is evident, that the natural consequence of the above-mentioned factors is to crystallize itself into a rise of the price of antimony and I am inclined to believe that all the time that these factors exist and are likely to continue, we are going to see, if not higher limits, at least a continuation for some time to come of those prevailing at the present moment.

Of course, it cannot be overlooked that buyers take the view, on account of the peace rumors, that prices are likely to be adversely affected, but it does not seem to me that—considering the present stocks—this will be the case, whereas the possibility of a return to pre-war prices, while the conditions mentioned continue to prevail, does not appear probable.

It must also not be overlooked that there is a marked falling off in the Bolivian ore shipments, which have been unable to stand the stress of the falling prices, demonstrating once more the preponderating position of the Chinese mines.

New York, January 10.

GOVERNMENT MILLS are operated in Western Australia, South Australia, and Victoria. These treat gold and tin ores. Queensland has recently started its first public mill. This is at Bamford, about 25 miles inland from Cairns on the coast of the northern part of the State. The five 1000-lb. stamps, tables, jigs, and vanners will treat wolfram ore, also tin ore from small mine-owners. The plant is well situated for this work.

THE BUNKER HILL SMELTER IN PROCESS OF CONSTRUCTION.

The Bunker Hill Smelter

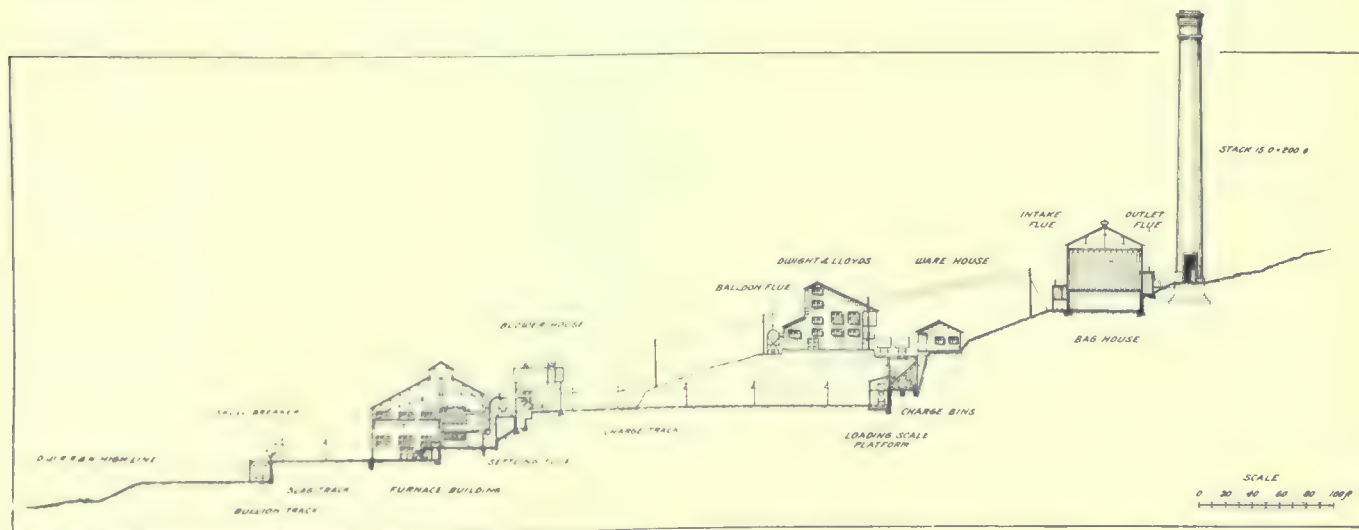

By Jules Labarthe

The site of the new Bunker Hill smelter and refinery is near Kellogg, in Idaho. The plant consists of a complete equipment for the sampling, roasting, sintering, smelting, and refining of gold, silver, and lead ores. The buildings will cover an area of 30 acres, and the equipment will consist of the following:

SAMPLING-MILL. The ore and concentrate will be received in standard-gauge railroad-cars and delivered to receiving-bins, from which the material will be removed by belt-conveyors to the crushing and sampling department. This department will have a capacity of 50 tons of ore per hour and will be equipped with a 10 by 20-in. Blake crusher, two sets of 36 by 14-in. rolls, also a set of 12 by 12 rolls, a 48 by 72-in. trommel, and four Vezin samplers. After crushing and sampling the material will be transferred by belt-conveyors to any one of eight large storage-bins. Each of these bins is provided with two apron-belt feeders by which the cor-

rect proportion from the bin can be fed to the belt-conveyor and delivered to the roasting-department.

ROASTING-DEPARTMENT. The roaster-building is of steel construction, 112 by 57 ft. in plan, and contains four 42-in. standard Dwight & Lloyd machines. These machines are to serve as a desulphurizing and sintering equipment. In addition to the Dwight & Lloyd machines there will be one multiple-deck Wedge roaster. This furnace will be used to give a pre-roast to lead matte or material carrying a high percentage of sulphur. The product of the Wedge furnace will be mixed afterward with the regular D. & L. charge for the purpose of further desulphurizing and sintering. The estimated capacity of each D. & L. machine is 100 tons per day. The capacity of the Wedge furnace is 50 tons per day. These furnaces are equipped with large storage-hoppers, which are filled by means of a belt-conveyor system that delivers the ore from the storage-bins. The sintered ma-

SECTIONAL ELEVATION OF BUNKER HILL SMELTER.

terial will fall from the D. & L. machines into standard-gauge hopper-bottom steel cars unloading into concrete storage-bins.

CHARGE-BINS. The blast-furnace will be fed from 24 bins of 3400 cu. ft. capacity each, divided as follows: eight bins for roasted and sintered material—these bins are constructed of reinforced concrete; eight bins of timber construction to be used for limestone, crude ore, slag, by-products, etc.; and eight timber bins for coke.

Each bin has two discharge-openings provided with arc-gates. Under each opening there is a four-ton capacity hopper-scale. The charge is accurately weighed from the bin to the hopper and held in the hoppers until delivered to the blast-furnace charge-cars. The hoppers and discharge-doors are so constructed that the material is delivered to the charge-car in a layer so that a bedding effect is obtained in the car itself.

In addition to the storage of approximately 400 tons of coke in the charge-bins there is a large coke-storage provided in the rear of the charge-bins where approximately 3000 tons of coke can be held and delivered from the storage to the charge-bins by means of a locomotive crane and clam-shell bucket.

BLAST-FURNACE DEPARTMENT. This building is of steel construction, 80 by 126 ft. The charges are conveyed in standard-gauge hopper-bottom special-design steel charge-cars from the charge-bins to the blast-furnace building. These cars are handled by four-ton electric locomotives. The cars discharge directly into the blast-furnaces. The charge-floor of the blast-furnaces is level with the bottom of the charge-bins.

The three steel-jacketed blast-furnaces are 42 by 180 in. at the tuyeres. The height of the furnaces from the centre of the tuyeres to the feed-floor is 20 ft. 9 in. Each furnace is provided with twenty 4-in. tuyeres. The estimated capacity of each furnace is 200 tons of ore per day. These furnaces are arranged with under-floor down-takes.

The furnace-building is provided with a 20-ton 4-motor traveling crane that serves the blast-furnaces and the refinery. The blast-furnace receivers or forehearth are made of cast-steel with trunnions, and can be lifted and changed by means of the electric crane.

The bullion will be delivered from the blast-furnaces to lead-pots. These pots in turn will be handled by the crane directly to the refining-department, which is under the same general roof as the blast-furnaces.

LEAD REFINERY. This building is an extension, 105 by 108 ft., of the steel blast-furnace building, and is served by the 20-ton crane, which also operates above the softening-furnace and desilverizing-kettles. There have been provided two 80-ton softening-furnaces and four 50-ton desilverizing-kettles. At an elevation of 10 ft. below this equipment there are two 80-ton refining-furnaces and four 50-ton merchant-kettles, namely those in which the refined lead is accumulated prior to casting in merchantable form.

The molten lead is removed by means of centrifugal

pumps from the merchant-kettles to the moulding-machines, which will be of the type designed by John F. Miller at Trail, B. C. These machines each have a capacity of approximately 15 tons of pig-lead per hour.

SILVER REFINERY. This building will be of brick construction, 60 by 82 ft., and contain eight large Faber du Faur furnaces, two cupelling-furnaces, one fine-silver furnace and a complete equipment for parting and precipitating silver. There will be crucible-furnaces for melting gold. The copper used in the precipitation of silver will be recovered in the form of copper sulphate. A complete plant for the crystallization of copper sulphate will be contained in a frame building adjoining the silver refinery.

POWER PLANT. The power-house is steel and brick construction, 35 by 40 ft. The electric power will be supplied by the Washington Water Power & Light Co. at a 2200-volt potential and the larger motors of the plant will be operated at that voltage.

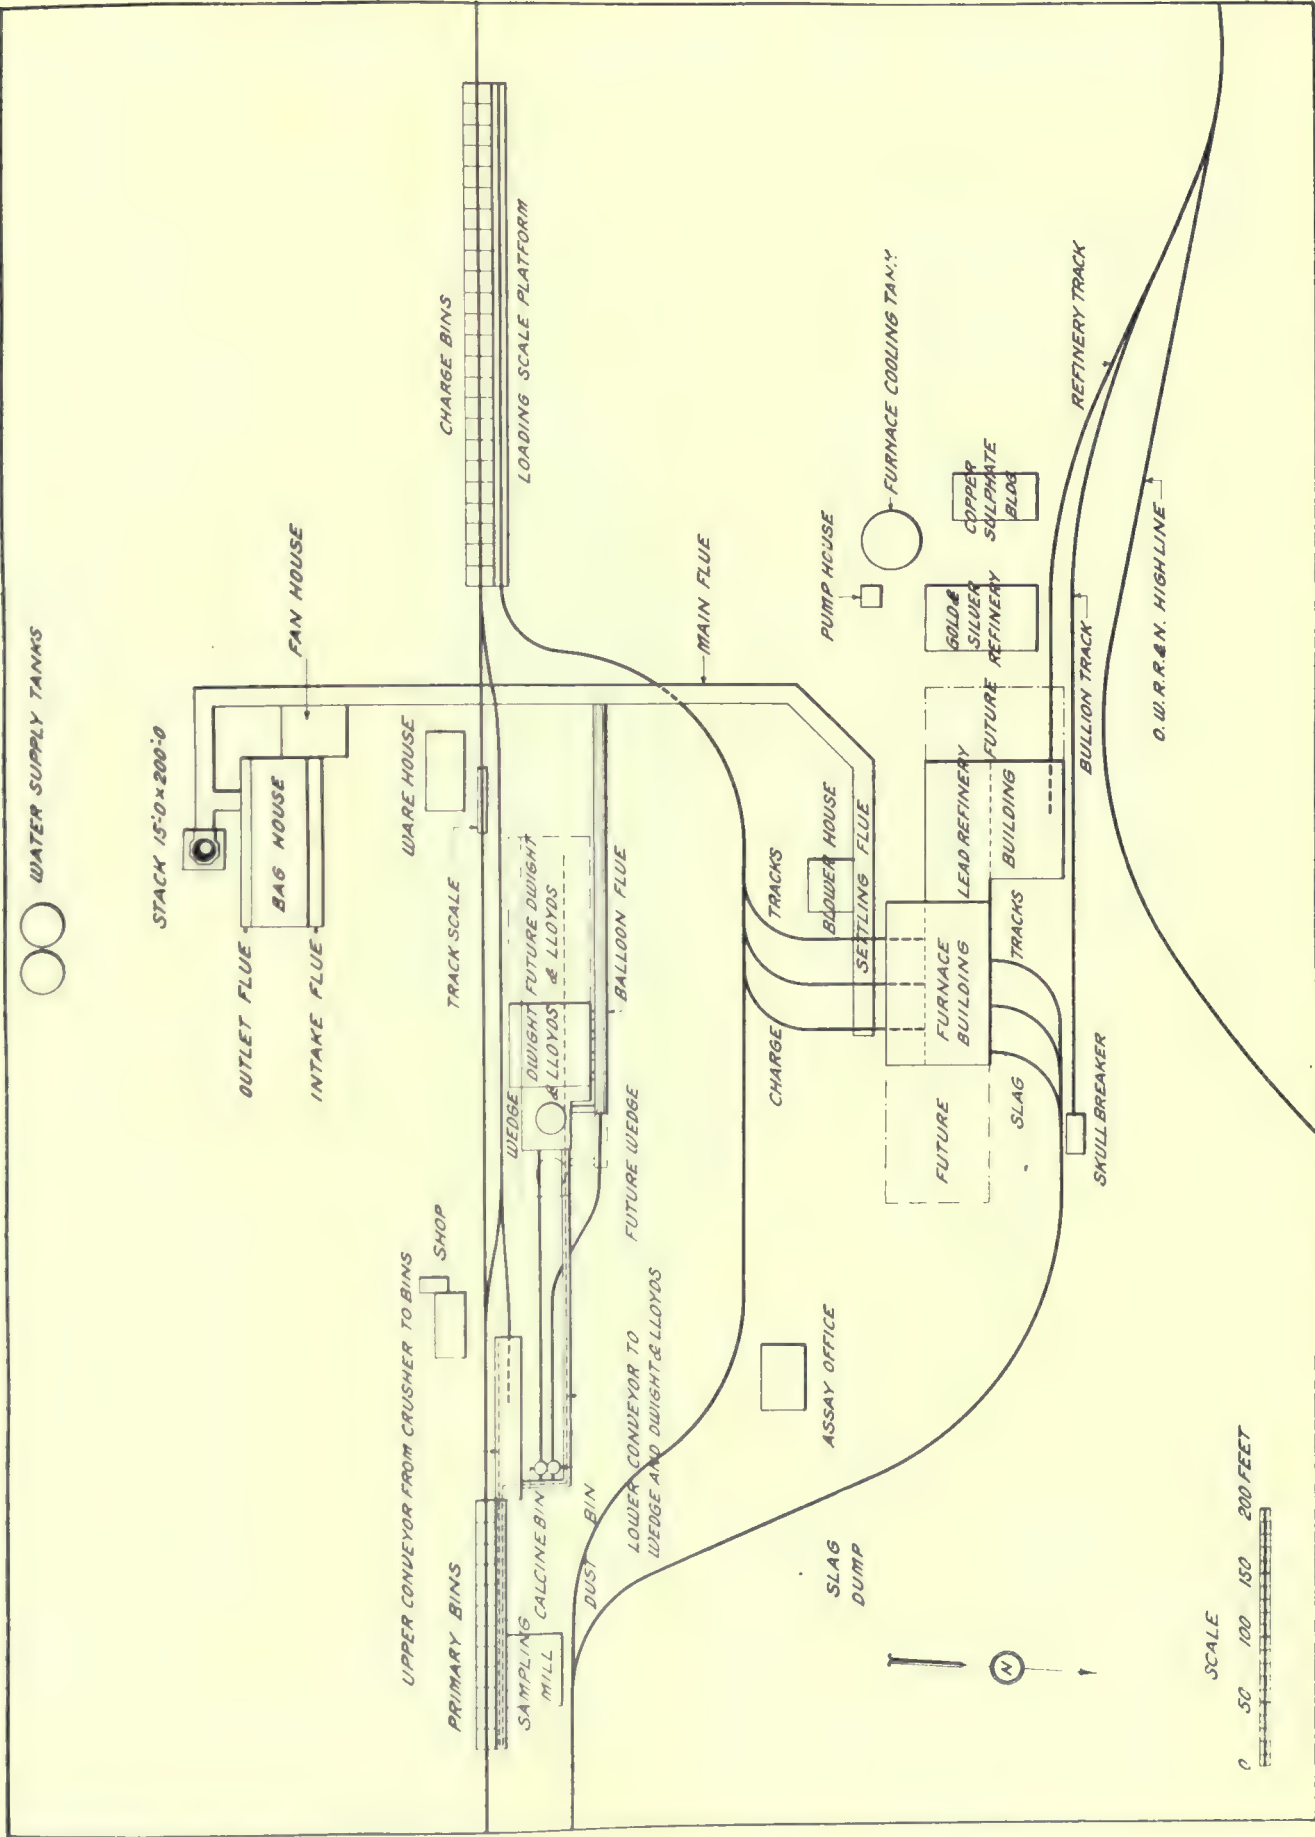

There are two Ingersoll-Rand turbo-blowers each with a capacity of 12,000 cu. ft. of air per minute at 48-oz. pressure. These blowers will be geared to two General Electric 200-hp. induction-motors. In addition, two 75-kw. motor-generator sets are provided, one to serve as an auxiliary unit. These sets are to supply direct current for trolley-locomotives and electric cranes.

FUME TREATMENT. The blast-furnace gases will be delivered to a bag-house through 600 ft. of brick dust-chamber. The bag-house is of brick and steel construction, 56 by 130 ft.; it is divided into three separate chambers above the thimble-floor. Each chamber contains 400 bags, or a total of 1200 bags. Below the thimble-floor there are 12 divisions to facilitate the removal of the collected fume. There have been provided two electrically driven fans of 60,000-cu. ft. capacity each, one fan to be held in reserve.

The gases from the Dwight Lloyd sintering-machines and Wedge roasting-furnaces are delivered through 400 ft. of steel balloon-flue to Cottrell tubes. The Cottrell apparatus has a capacity of 60,000 cu. ft. of gas per minute. The building is entirely of steel. All the gases, after passing through the bag-house and Cottrell tubes, are delivered to a Custodis brick chimney of 15-ft. internal diam., 200 ft. high.

GENERAL EQUIPMENT. The plant will be complete, with brick assay-office and laboratory building, 46 by 46 ft., warehouse, machine-shop, dry-house, and office. There will also be a high-pressure fire-system, complete electrical system, and sewerage.

COAL MINERS in Australia are apparently always making fresh demands on their employers. During November last the collieries were idle at Newcastle and other districts on account of the men demanding that their 8 hours should include from 'bank to bank,' that is, that work commence and end at the shaft collar. The strike was declared off when the board appointed to deal with the dispute ordered a resumption of work by conceding the men's demands.

Treatment of Manganese-Silver Ore

By Walter Neal

*Prior to the revolution in Mexico considerable interest was taken in the problem of treating the manganese-silver ore of the El Favor mine, in the Hostotipaquillo district, Jalisco. Since April 1914 the mine has been idle, but experiments have been continued in the United States by Mr. Neal and others. While the work is not complete, the progress detailed in this article is well worthy of record.

The insolubility in cyanide of the silver in several ores where it is accompanied by manganese oxides is well known. The problem is complicated by the fact that the exact nature of the rebellious mineral is not known—whether there is a definite chemical combination of the manganese and silver, or whether the manganese functions as an insoluble coating over the silver mineral is not yet established. Not all silver ores carrying manganese oxides are rebellious, and not all the silver in a given rebellious ore is insoluble. Generally, in an ore from a given orebody a definite amount of the silver is soluble and the rest quite insoluble. Furthermore, the ratio of soluble to insoluble silver does not vary with the manganese-content of the ore, nor does the total silver-content vary with the manganese-content. Only the manganese occurring as oxide interferes with the solubility of the silver in the ore, and silver occurring with rhodonite or rhodochrosite is usually quite soluble. For this reason it has been usual, where trouble with extractions has been traced to the presence of manganese, to seek more docile ore in depth, leaving the oxidized ore to be treated at some future date.

The El Favor lode is an almost vertical vein of quartz in andesite. The ore is highly silicious and darkened by manganese oxides. An analysis of a representative sample shows:

	%		%
Manganese	3.49	Copper	Trace
Sulphur	0.67	Silver, ounces per ton...	.20
Iron	0.70	Gold, ounces per ton...	0.075
Calcium	0.42		

Manganese is present in the form of oxide in the upper levels of the mine, although rhodonite and rhodochrosite also appear on the lower levels. Iron is present both as pyrite and as oxide. Silver in the higher-grade ore is often observed as a chloride, but direct observation of its rebellious form in the ore under discussion is lacking. A trace of copper appears in the concentrate, but the amount is so small that it is not found by assays of the ore. Gold generally occurs in a ratio of 3:1000 of silver. The gold is readily soluble in cyanide, and extractions of over 90% are consistently obtained in the mill. The ore

yields to milling 10% of its silver as a concentrate, assaying from 100 to 150 oz. per ton, and 40 to 45% as bullion from the cyanide plant.

F. B. Laney, microscopist of the U. S. Bureau of Mines' Experiment Station at Salt Lake City, considers that the predominating silver mineral both in the high-grade flotation concentrate and in the gravity concentrate from the same is proustite. It reacts for silver and arsenic. Bismuth and antimony are absent. Galena, sphalerite, chalcopyrite, and covellite are present in minute quantities. The manganese is present as a mixture of oxides, principally psilomelane, and possibly pyrolusite.

The first serious work done on the metallurgy of the ore was in 1911, when E. M. Hamilton was commissioned to make a study. After investigating various possible processes, he recommended the removal of the manganese by solution in sulphurous acid with cyanidation of the bleached tailing. This treatment promised an extraction of 90% of the silver, and, so far as could be determined by experiments on a laboratory scale, offered an acceptable process. In view of the expense of installing a test-plant on an adequate scale, it was decided to exhaust other possibilities first. Consequently, when Mr. Neal took charge in the following year, it was with Mr. Hamilton's excellent report before him, and with the determination to try any and every process that offered the slightest promise.

The first step in testing was to exhaust the possibilities of hydraulic concentration. Experiments made locally offered no promise along lines of wet concentration, and the vanners were finally scrapped, leaving only the Wilfleys in the concentration department. Other processes were investigated, among the first being that of the Huff Electrostatic Separator Co. Experiments were conducted at the Boston Institute of Technology under the direction of E. D. Bugbee. After preliminary tests with various processes, he recommended magnetic separation on Wetherill machines, followed by chloridizing-roasting and cyaniding of the product, and direct cyanidation of the Wetherill tailing. This process undoubtedly offered an improvement. One objection to adopting it at El Favor was that it involved dry crushing and it was hoped that a wet process could be developed that would be more easily adapted to the equipment at present installed at the mill. An elaborate series of tests was carried out by the Henry E. Wood Ore Testing Co. of Denver. After describing various tests in detail, they summarize: "The results of standard treatment by concentration and cyanidation are so thoroughly established that we consider it ill-advised to test further along those

*Abstract from *Journal of Chem. Met. and Min. Soc. of South Africa*, August, September, and October 1916.

lines. We do, however, have to advise that we tested by concentration, passing the tailing re-ground through a special bromo-cyanide treatment with no benefit." As chloridizing-roasting appeared to them to be the most promising lead, they made an elaborate series of tests, which they summarize as follows: "We conclude that you are justified in demanding a recovery by a 2% salt roast and cyaniding of 70%; plus concentration, 80.50%; and by exact chloridizing and cyanidation you should obtain 85%." The problem was next passed to the Wedge Mechanical Furnace Co. The preliminary tests indicated a volatilization of 12½% of the silver during roasting; this could probably be recovered in a scrubbing-tower, and promised an extraction of 76.7% of the silver by cyanidation following chloridizing, thus agreeing fairly well with the Denver opinion.

While on the subject of roasting, it may be mentioned that tests made by S. D. Kempton, roasting with 2% of salt and cyaniding the product for 64 hours with a 0.5% cyanide solution, gave a recovery of 82.3%, by assay of the tailing; also that work done in the laboratory of the El Favor Mining Co. confirmed the above results, and demonstrated that a short roast (less than 15 minutes) was quite sufficient for effective chloridizing. At the time the mine was abandoned, a small furnace of the Stetefeldt type was under construction to test the roasting idea on a larger scale.

In view of the tests above cited, there seems to be no doubt that an extraction of 80%, less volatilization losses, should be obtained by chloridizing-roasting followed by cyaniding. Experiments made at the El Favor mine, and checked at Salt Lake City, on reduction of the manganese by roasting in a reducing atmosphere, gave promising results. Elmer E. Carey reported an extraction of 25.6% by his process of electro-amalgamation. The Parks Electro-Cyanide Co. succeeded in extracting 40% of the silver in the form of amalgam in seven hours, with a consumption of 5.28 lb. cyanide per ton of ore. Concurrently with this work an active campaign was carried out at the mine by Mr. Neal and the mill superintendent, H. L. Wilson, both in the plant and in the laboratory. By the time-honored expedient of getting the tonnage up and the costs down and by improving the mechanics of the treatment, the business was made to show a profit, but the main problem remained unsolved, and they had to contend with a loss of 50% of the silver in the tailing.

All the work done on El Favor ore has indicated the necessity of completely decomposing the manganese in the ore before a satisfactory silver extraction can be obtained. A large number of tests were made with the result that sulphuric acid, with some chemical capable of taking up oxygen readily, proved to be the best and cheapest method of decomposing the manganese. The chemicals giving the best results were hyposulphite of soda, oxalic acid, sulphate of copper, and ferrous sulphate.

The last work done at the mine was to investigate the possibility of treating the concentrate at the mine. A

process that Mr. Neal was preparing to try on a large scale consisted of saturating the concentrate with gas-oil—crude oil might have served as well—and then giving a quick roast in a covered dish in a hot muffle. Three to five minutes in a hot muffle gave the best results. After roasting, the concentrate was re-ground to pass 200-mesh and treated in the usual way with a 0.5% solution of cyanide. Three or four agitations of 10 hours each proved satisfactory, and reduced the silver-content from 136 to 13.6 oz. per ton. Wet methods of treating the concentrate were not at all satisfactory, as the concentrate contained a large amount of black residue, rich in silver, that could not be decomposed by sulphuric acid and ferrous sulphate.

John D. Fields of Maxville, Montana, proposed to treat the ore in his electro-flotation cell, and for a time great hopes were entertained of this process. Results, however, were erratic, and occasional promising extractions were offset by the part failure of confirmatory experimenting.

Continuing the work of Messrs. Hamilton and Wilson, some hundreds of tests have been made on processes involving the removal of the manganese with sulphur dioxide. Attention was also turned to a double treatment involving the removal of the manganese with sulphur dioxide and ferrous sulphate, with cyaniding of the bleached tailing. A feature favorable to this process, when compared with the 'hypo' process lies in the fact that the ore contains a small quantity of gold, which is soluble in cyanide, but not in 'hypo.' It became evident at this stage that after complete dissolution of the manganese all the silver was soluble in cyanide solution.

In the meantime developments in the flotation of the silver have been so encouraging as to make Mr. Neal speculate whether that did not offer a solution of the problem. During the past winter, by courtesy of the U. S. Bureau of Mines, he had the freedom of the Experiment Station at the University of Utah, as also the advice and assistance of the metallurgists of the Bureau. Flotation of the raw ore gave unpromising results. As a matter of record it may be stated that flotation was attempted in solutions of lime, cyanide, 'hypo,' caustic potash, sodium carbonate, and sulphuric acid, with coal-tar creosotes, wood-creosotes, various pine and pine-tar oils, cedar-oils and others for frothing reagents. Three lots of concentrate totaled 29.9% recovery. Cyanide treatment of the tailing extracted a further 32.4% of the silver, making a total extraction of 62.3%. The concentrate, however, is too low-grade to be considered a commercial product. Flotation after sulphidization with various reagents was next tried. Sulphuretted hydrogen gas, sodium sulphide, and calcium polysulphide all are effective. Any one of these serves the purpose, but most of the work was done with sodium sulphide (fused, carrying 60% Na₂S) on account of its being available in a convenient form. At El Favor calcium polysulphide made locally would probably prove the least expensive.

It was learned early that the silver rebellious to cyanide was equally rebellious to flotation. That is to say,

flotation as developed up to the present time appears to have no effect on the rebellious silver, recovering only the silver mineral soluble in cyanide. This certainly is unfortunate; were it the other way the manganese-silver problem would be solved by flotation of the cyanide tailing or the reverse. A few tests, however, demonstrated that the flotation-concentrate yields its silver to cyanide, whereas the silver remaining after flotation is insoluble in cyanide. Furthermore, flotation after cyanidation fails to yield a silver-bearing concentrate. It would appear therefore that while the results of flotation experiments are especially interesting at this time on account of the scarcity and high price of cyanide and zinc, they do not offer a solution of the manganese-silver problem as such. The sodium sulphide used for sulphidizing the ore has a double action on the silver: The soluble silver is sulphidized and rendered floatable, and in addition a part of the rebellious silver is altered to a form soluble in cyanide. This recalls the Wood report to the effect that sodium sulphide reduces the manganese and frees the silver to cyanide. The observation as to its erratic behavior is also confirmed in that while a 10 to 20% additional extraction is consistently maintained, Mr. Neal has not been able so far, by a series of careful experiments, to better this result, even by the use of a large excess of the reagent.

Another interesting point is that by concentration of the tailing from flotation plus cyaniding, an additional 10% of the silver in the ore can be recovered in the form of a concentrate of commercial value. As high as 100 oz. silver per ton has been attained. That is to say, a sample that had been properly sulphidized and floated in the Janney machine, and the tailing from this cyanided, would yield a further 10% extraction by table concentration of the cyanide tailing. It is to be noted that this is just what is normally extracted on the Wilfley tables in the El Favor mill, and it seems likely that the operation of the Wilfleys in conjunction with a flotation unit would increase the recovery by that amount.

The sulphidization of the ore is accomplished by simply agitating in a weak solution of the alkaline sulphide. At the outset this was done in a bottle previous to flotation, but the time was gradually shortened to a point where the operation was carried out right in the flotation machine. The total extraction by flotation, plus cyanidation, plus concentration, is therefore 71.3% of the assay value.

SUMMARY. The processes investigated in this research fall naturally into two classes—those requiring dry crushing and those adapted to a wet pulp. Considered strictly on their merits as metallurgical processes, Mr. Neal prefers the former, and is of the opinion that either a chloridizing or a reducing roast, followed by cyaniding, offers an acceptable process for ores of this class. The El Favor mill, however, is arranged for wet crushing, so that under anything like equal efficiency a process adapted to wet crushing would have the preference. The chloridizing roast on these ores is not new. The reducing roast is, so far as Mr. Neal is aware, untried on a working

scale, but as the volatilization loss would be less than that expected in salt-roasting, and might easily be *nil*, the process has merits that deserve serious consideration. The low grade of the concentrate obtained by magnetic and electro-static processes, necessitating local treatment of the concentrate, is a serious disadvantage; and it is questionable whether the apparent advantages would not be off-set by the greater complexity of plant required. Almost certainly this would be the case in a small mill. The Hamilton process, modified by the use of additional reagents, appeals strongly on account of the high extractions obtained. It is the only process tried that can be said to offer a real solution of the trouble—the others are makeshifts. In the practical application of this process there seems to be no way of avoiding a double treatment, the first working in acid solution and the second in alkaline. A solvent for silver that would not be destroyed by acid, or that would be so inexpensive that a considerable loss could be allowed, would solve the problem, but none is known. The loss of sulphur in the process is an unknown factor, and until the result of commercial operation is made known, it is likely to remain so. The flotation process does not profess to solve the difficulty, but possesses many features that are attractive at the present time. Even if the Mexican would compose his affairs, it is a question whether the El Favor could count on securing a steady supply of cyanide. Further, at the present prices of cyanide and zinc, it appears that the cost of realizing the silver in a high-grade concentrate might well be less than the cost of producing silver bars at the mine by cyanidation. A flotation unit is a comparatively inexpensive machine, and could be put in at the El Favor mill without material alteration of the flow-sheet. The process could indeed be tried on a commercial scale at less expense than would be incurred by a similar test of any of the other processes proposed.

In the discussion of Mr. Neal's paper, H. A. White, vice-president of the Society, considered it obvious that some oxide of manganese is responsible, and then only when all the silver is not in the form of sulphide. This deduction is based on experiments. Probably no method that does not involve the destruction of MnO_2 can yield a high extraction. Research must therefore be made in this direction, one suggestion being to utilize the fact that carbon monoxide at low temperatures, even below red heat, has a powerful action upon manganese di-oxide. F. Wartenweiler gave results of tests made in 1907-8 on a silver-gold tailing and ore carrying pyrolusite in large quantity. The tailing, assaying 4.2 oz. of silver and 0.05 oz. of gold per ton, was leached with an 18% salt solution, which had been charged with chlorine electrolytically generated by passing through an absorption-tower. The recovery was 64.3% of the silver and 75% of the gold. The precious metals were precipitated on lead shavings. The partly oxidized silver-gold ore was roasted with 4% of salt, then leached with the salt solution (18% NaCl and 0.2% free Cl), giving an extraction of 90.7% of the silver and 75% of the gold.

FIG. 5. ANOTHER VIEW.

Zinc Oxide From Lead Slag

By H. B. Pulsifer and George Perlstein

INTRODUCTION. The noteworthy process that Hedges and Divine inaugurated at South Chicago last year for the recovery of zinc from lead blast-furnace slag is being used with such success that it is worth describing in some detail.

The material from which the zinc oxide is recovered is waste slag from the former lead-smelting and lead-refining operations of the once active National plant of the American Smelting & Refining Co. on the lake-front at South Chicago. The process consists in again putting this slag through a blast-furnace with excess of coke and some limestone. The zinc is expelled from the slag, partly by reduction and partly by replacement, the vapor burns to oxide in the stack and flues and is caught in bags after the gases have been sufficiently cooled.

After one year's operation under lease by Hedges and Divine the company failed to renew their lease and is now operating for itself under much greater pressure. A second furnace has been installed, extensive flues constructed, and a new bag-house to accommodate 1200 bags, each 20 in. by 30 ft. By crowding both the furnaces and the new facilities for cooling and bagging, the tonnage treated has been

greatly augmented, allowing a probably greater margin of profit. We shall not attempt to give any details of the most recent developments but hold ourselves to the

FIG. 1. THE REMODELED LEAD FURNACE.

operations of the year from April 1915 to April 1916, when the plant was under the control of B. F. Hedges and R. D. Divine.

CHEMISTRY OF THE PROCESS. Although the process itself is extremely simple, the chemistry is not as yet sharply defined. This is probably due to the lack of

knowledge as to the exact composition of the raw material. In the old slags the zinc is presumably present as oxide, silicate, and oxide dissolved in silicate. Messrs. Hedges and Divine first worked on the hypothesis that the zinc was present mainly as oxide; later they came to the conclusion that the silicate predominates.

What zinc is freed has to be reduced to the metallic state and have its vapor forced up through the charge column. With from 25 to 35% of coke on the charge the reduction is strong and the temperature high, as lead-furnaces go. Very likely the silicate of zinc, and much of the oxide dissolved in the silicate, resists even this strong reduction, for, as run during the first year, only about half of the contained zinc was recovered.

A particular balance of conditions was finally hit upon as best expressing the economics of the smelting. The slag contained some 2% of lead and if the temperature of the smelting-zone became too hot all of this lead would be driven off with the zinc vapor. Too gentle reduction failed to yield much zinc. Accordingly, it was found most satisfactory to maintain a condition which would let the lead run out as metal with the slag, thereby being recovered as bullion, while some 50% of the zinc was given off from the slag. Thus a low lead oxide was available for the market and a silver-lead bullion made an additional source of profit.

We are informed that the most recent operations are nearly a continuation of this practice; possibly less attention being given to recovering the lead in the first furnace, while the slag from the first furnace is re-smelted in the second with further recovery of the zinc. The oxide recovered is thus a mixture, and with such a high zinc extraction the lead is not unduly high after all.

During the first year of operations, when the only furnace was run much like an ordinary lead-furnace except for the excess coke and hot-top, considerable lead-bullion and antimonial-speiss were separated from the slag and amounted to a large part of the profit. During this period also the chemical end of the process finished immediately over the charge; with the burning of the mon-oxide and zinc vapor in the large brick stack of the furnace, directly after exit from the layers of charge, nothing further remained but to cool the gas and fume and collect the latter in suitable receptacles.

OUTLINE OF MECHANICAL OPERATIONS. Owing to the rather compact arrangement of slag, furnace, flues, and bag-house the mechanical operations are brief and direct to the point.

A Browning locomotive-crane raises the raw material from the old dumping-ground, be it slightly above or even below the level of the lake-water. A run of a few yards and the bucket is opened over the high hopper which feeds into buggies at the end of the furnace.

Men push or shovel the charge-mixture through the low opening onto the top of the charge-column. An illustration of the furnace-stack and the low feed-openings was given in an article on this same subject in *Metallurgical and Chemical Engineering* of November 1, 1915, by the senior author. A steel flue leads horizontally from

just above the feed-floor level through which the fume and gases pass toward the bag-house.

Fig. 1 shows the remodeled furnace as adapted to the new operations after its many years of smelting for lead. It is seen that the crucible was raised a foot above its former height and the well discontinued. This was to give elevation for the flow of slag through a small settler into the granulating-tank at the edge of the building.

Fig. 2 is taken from the edge of the tank and shows the slag flowing from the furnace through the settler. The slag is tapped at intervals and although rather short with lime is fluid enough to reach the water and granulate nicely. A bottom tap in the settler allows the bullion to be run into molds; the speiss (often mixed with matte) is broken away from the slag and piled until enough accumulates to make a shipment to some other lead-refinery. The granulated slag is raised by the crane and returned to a new pile near its original location.

Coke and limestone are received and delivered by the equipment remaining from the former smelting operations of the plant.

It is understood that the 1916 improvements have only slightly altered the arrangements, as would be necessary by the installation of the second furnace at the side of this No. 1 furnace.

The first year of operating the gases and fume traveled through a length of flue some 700 ft. long before reaching the fan, the bagging system, and passing into the main 150-ft. stack. This flue had various sizes and shapes of section and has been completely discarded this year.

Large and long steel flues have replaced the smaller ones of former days; the Prinz & Rau machines have given place to the huge bag-house seen in Fig. 3. For some time they used the outside levers to shake the bags as actually posed in Fig. 4. It is understood that this device did not prove satisfactory, for the levers are little used of late. Doubtless the bags are now shaken by hand inside and individually.

The general character of the steel flue is evident from Fig. 5, which shows it elevated to cross over the tracks just before connecting with the fan and thence to the bag-house. In this view the bag-house is still only partly finished.

When the Prinz & Rau machines were used the zinc oxide collected in the little bags was delivered directly into paper bags that were piled in cars for shipment. An attendant had merely to remove the bags as they became full and place an empty one. With the new methods and larger tonnage, other ways of handling and packing are of course used.

It is thus seen that this method of recovering zinc oxide is remarkably simple in principle and operation. The most approved recent practice does not allow large amounts of zinc in lead ores, as formerly, but lead refineries using the Parkes process do still discard great amounts of zinc from the desilverization to get ultimately into a blast-furnace slag. A more efficient zinc recovery is not yet generally accepted, although Divine worked

out a promising method* at this same plant before it was abandoned as a lead-refinery.

It was naturally inferred that if the new recovery would work on the old National dumps it could also be used to profit wherever a similar dump contained a suitable amount of zinc. Hedges & Divine some time ago leased the old dump at Aurora, Illinois, and soon will be recovering oxide from that plant's former operations. The American company also started the process on slag at the Omaha (Nebraska) plant, and, in a rather small

2400 lb.; coke, 600 lb.; limestone, 290 lb. Every 20 minutes one of these charges would be shoveled into the furnace by hand.

The old smelting-plant had two rectangular lead-furnaces, five water-jackets with five tuyeres on each side. One furnace was torn down at the dismantling of the plant but the one salvaged by Hedges & Divine was lengthened out to nine tuyeres on a side. The curb was raised a foot and the crucible filled to slope from the back to the single tap at the front. The cast-iron jackets are an inch thick and fitted with the tuyere-boxes as in Fig. 1. The remodeled furnace has thus a size of 46 by 156 in. at the tuyeres and a 12-ft. charge-column.

FIG. 2. RUNNING SLAG THROUGH THE SPOUT AND SETTLER TOWARD THE GRANULATING-TANK.

way, are doing the same thing there. The process is more than likely to extend to any suitable dump in the West where conditions for marketing the oxide may allow profitable work.

DETAILS OF THE BLAST-FURNACE. As the gist of the whole process lies in the blast-furnace work a few details as to how operations were carried out by Hedges & Divine will conclude our account.

The dump-slag analyses to average silica, 33%; lime, 20%; iron oxide, 18%; zinc, 12%; lead, 1.5%. The furnace was run under 12-oz. blast-pressure to smelt 65 tons of slag in 24 hours. Charges were made up of slag,

FIG. 4. OUTSIDE LEVER-SHAKING AT SOUTH CHICAGO.

The furnace is run with the top almost at a red heat; in fact, it is quite so just before a fresh charge is shoveled in. The charge decrepitates vigorously while the gases flicker with a greenish flame as the monoxide and zinc vapor burn at the inrush of air through the feed-doors.

Little chemical work was found necessary for smelting control because the slag had, of course, once flowed from a furnace and with the new replacement of zinc for lime would be even more fusible than at first.

The Iroquois Iron Works has recently purchased the eight or nine acres of the old National plant for \$107,000 and the American company will doubtless hasten to recover as much oxide as possible before the ground has to be turned over to its new owners.

*Trans. Am. Inst. Min. Engrs., XLIX; 814 (1915).

The Miami Appeal

INTERPRETATION OF THE FIRST PATENT IN SUIT BY THE SUPREME COURT

*The first finding of the Supreme Court relative to patent No. 835,120 is set forth in the following statement quoted from the court's opinion:

"It is clear that in the prior art, as it is developed in this record, it was well known that oil and oily substances had a selective affinity or attraction for, and would unite mechanically with, the minute particles of metal and metallic compounds found in crushed or powdered ores, but would not so unite with the quartz, or rocky non-metallic material, called 'gangue.' Haynes' British patent (1860), and United States patents, Everson (1885), Robson (1897) and Elmore (1901). It was also well known that this selective property of oils and oily substances was increased when applied to some ores by the addition of a small amount of acid to the ore and water used in process of concentration. United States patents, Everson (1885), Elmore (1901), and Cattermole (1904)."

The precise function performed by the "selective affinity" of oil and the reason that acid increases this selective affinity do not appear to be well understood, but the facts were, as stated by the court, known long before date of the first patent in suit.

The art antecedent to patent No. 835,120 is stated by the Supreme Court to be divided into two classes. The court states its views upon this point in the following passage quoted from its opinion:

"The processes, of this general character, described in the prior patents may be roughly divided into two classes. The process in the patents of the first class is called in the record the 'Surface Flotation Process' and it depends for its usefulness on the oil used being sufficient to collect and hold in mechanical suspension the small particles of metal and metalliferous compounds and by its buoyancy to carry them to the surface of the mixture of ore, water, and oil, thus making it possible, by methods familiar to persons skilled in the art, to float off the concentrate thus obtained into any desired receptacle. The waste material, or gangue, not being affected by the oil and being heavier than water, sinks to the bottom of the containing vessel and may be disposed of as desired.

"The process of the other class, called in the record the 'Metal Sinking Process,' reverses the action of the Surface Flotation Process and is illustrated by the Cattermole U. S. patent, No. 777,273, in which oil is used to the extent of 4% to 6% to 10% of the weight of the metalliferous mineral matter, depending on the char-

acter of the ore, for the purpose of agglomerating the oil-coated concentrate into granules heavier than water, so that they will sink to the bottom of the containing vessel, permitting the gangue to be carried away by an upward flowing stream of water."

After so classifying the prior art the Supreme Court defines the process of patent No. 835,120 as follows:

"The process of the patent in suit, as described and practiced, consists in the use of an amount of oil which is 'critical,' and minute as compared with the amount used in prior processes 'amounting to a fraction of one per cent on the ore,' and in so impregnating with air the mass of ore and water used by agitation—"by beating the air into the mass"—as to cause to rise to the surface of the mass or pulp, a froth, peculiarly coherent and persistent in character, which is composed of air bubbles with only a trace of oil in them, which carry in mechanical suspension a very high percentage of the metal and metalliferous particles of ore which were contained in the mass of crushed ore subjected to treatment. This froth can be removed and the metal recovered by processes with which the patent is not concerned."

It will be noted that in the passage above quoted the Supreme Court distinctly and explicitly defines the patented process as comprising all of the following named factors: (1) the use of a minute quantity of oil "amounting to a fraction of one per cent on the ore"; (2) impregnating the mass of ore and water with air "by agitation—"by beating the air into the mass"; and (3) so "as to cause to rise to the surface of the mass, or pulp, a froth, peculiarly coherent and persistent in character."

As will appear in the discussion of the process practiced by defendant, defendant does not introduce air "by agitation—by beating the air into the mass," and does not form a froth that is "peculiarly coherent and persistent in character," but, on the contrary, defendant's process results in the formation of bubbles so fragile and evanescent that they exist only while supported by the incoming current of air and which collapse instantly the air supply is terminated. The instrumentality for introducing air employed by defendant is different from that described and claimed in patent No. 835,120 and found by the Supreme Court to be characteristic of the patented process, and the resulting bubbles or froth are as transient as any material thing can be and still exist, and in this respect are diametrically opposite to the "peculiarly coherent and persistent" froth which the Supreme Court finds to be a distinguishing characteristic of the process described and claimed in patent No. 835,120.

*Abstract from brief presented by the defendants to U. S. Circuit Court of Appeals for the Third District, in suit with Minerals Separation, Ltd.

The process described and claimed in patent 835,120 is further defined by the Supreme Court as comprising the introduction of air into the mixture by agitation in the following passage from the opinion of the Supreme Court, in which passage the court states that the extent of agitation was increased as the amount of oil was progressively decreased.

"It was promptly recognized by the patentees that this froth was not due to the liberation of gas in the mass treated by the action of the dilute acid used, and its formation was at once attributed in large part to the presence of the air introduced into the mixture by the agitation which had been resorted to to mix the oil with the particles of crushed ore, which air, in bubbles, attached itself to the mineral particles, slightly coated as they were with what was necessarily an infinitesimal amount of oil, and floated them to the surface. The extent of the agitation of the mass had been increased as the experiments proceeded until the 'series of Gabbett mixers, fitted with the usual baffles, were speeded at from 1000 to 1100 revolutions per minute.'"

Following the passage above quoted the Supreme Court quotes a passage from the testimony of plaintiff's expert, Adolf Liebmann, stating that the court is convinced that this expert has not overstated the facts. The court, in effect, adopts the expert's statement as a statement of the court's finding. Following is the part of Dr. Liebmann's testimony quoted and adopted by the Supreme Court:

"The present invention differs essentially from all previous results. It is true that oil is one of the substances used, but it is used in quantities much smaller than was ever heard of, and it produces a result never obtained, before. The minerals are obtained in a froth of a peculiar character, consisting of air bubbles which in their covering film have the minerals embedded in such manner that they form a complete surface all over the bubbles. A remarkable fact with regard to this froth is that, although the very light and easily destructible air bubbles are covered with a heavy mineral, yet the froth is stable and utterly different from any froth known before, being so permanent in character that I have personally seen it stand for twenty-four hours without any change having taken place. The simplicity of the operation, as compared with prior attempts, is startling. All that has to be done is to add a minute quantity of oil to the pulp to which acid may or may not be added, agitate for from two and one-half to ten minutes and then after a few seconds collect from the surface the froth which will contain a large percentage of the minerals present in the ore."

In the passage above quoted the first characteristic of plaintiff's process dwelt upon is the use of a small amount of oil; the next characteristic referred to is the "froth of a peculiar character" resulting from the process; next is a reference to the fact that "the froth is stable and utterly different from any froth known before," after which it is stated that the froth is so per-

manent in character that it will stand for twenty-four hours without change; the last characteristic of the process referred to is the necessity of agitating the mixture for the purpose of producing the froth. Except for the fact that defendant uses the most economical quantity of oil possible in its operations there is absolutely nothing in common between defendant's process and that defined in the above quoted passage. The froth formed as a result of defendant's process has not the peculiar characteristics referred to, the mineral in the froth does not form a complete surface over the bubbles, the froth is not stable, the froth is not different from previous froths, but is identical with that formed by the use of antecedent processes, the froth formed by defendant is not so permanent as to remain unaltered for twenty-four hours or for twenty-four seconds, but collapses instantly upon cessation of the air supply through the porous bottom of the vessel; and, furthermore, defendant does not bring about the introduction of air and froth formation by agitation, but, as above stated, by causing air bubbles to percolate upwardly through the porous bottom of the vessel containing the mixture.

In the part of the opinion of the Supreme Court following the passage above quoted the court again defines the process of patent No. 835,120 in the following terms:

"It is not necessary for us to go into a detailed examination of the process in suit to distinguish it from the processes of the patents relied on as anticipations, convinced as we are that the small amount of oil used makes it clear that the lifting force which separates the metallic particles of the pulp from the other substances of it is not to be found principally in the buoyancy of the oil used, as was the case in prior processes, but that this force is to be found, chiefly, in the buoyancy of the air bubbles introduced into the mixture by an agitation greater than and different from that which had been resorted to before and that this advance on the prior art and the resulting froth concentrate so different from the product of other processes make of it a patentable discovery as new and original as it has proved useful and economical."

In the passage above quoted the Supreme Court, by implication, finds that the prior art processes depend upon the buoyancy of the oil to float the mineral, while the process of patent No. 835,120, using a small amount of oil, is found to depend upon the buoyancy of the air bubbles introduced into the mixture by agitation. The court goes farther and defines the agitation forming part of the process of patent No. 835,120 as "greater than and different from that which had been resorted to before," thus explicitly limiting patent No. 835,120 to the combination of the use of a small amount of oil not only with agitation, but with agitation of a peculiar character, namely, "agitation greater than and different from that which had been resorted to before." The court then states that the procedure so defined constitutes an "advance on the prior art," and the court finds

that "the resulting froth concentrates so different from the product of other processes make of it a patentable discovery." Language could not be framed more explicitly defining and limiting the process of patent No. 835,120 as deriving its novelty and patentability not from the small amount of oil merely, but from the combination of the use of such small quantity of oil with a greater and novel agitation giving rise to a new result, namely, froth concentrates different from the product of prior processes. In view of this explicit interpretation of patent No. 835,120, we maintain that the Supreme Court has excluded from the scope of patent No. 835,120 operations such as practiced by defendant, wherein there is no mechanical agitation whatever for the purpose of introducing air, wherein no mechanical agitation at all is necessary for any purpose, to say nothing of a peculiar and novel degree of agitation, and wherein the result is not the new result defined by the Supreme Court, but is the result attained in prior processes in which air was introduced into the mixture in precisely the manner practiced by defendant.

In reference made by the Supreme Court to decisions made by the British courts the Supreme Court again expresses its conclusion that one of the elements of novelty of the process of patent No. 835,120 is the floating of the mineral particles by the buoyancy of the air bubbles as distinguished from floating the particles by the buoyancy of oil. Nowhere in its opinion, however, does the Supreme Court, even by implication, suggest that patent No. 835,120 confers a monopoly for the flotation of mineral particles by the buoyancy of air except in combination with the other features of the patented process, namely, agitation of a peculiar character to beat air into the mixture and the resulting formation of a froth of concentrates different from the product of prior processes. The prior art contains many instances of the flotation of mineral particles by the buoyancy of air and other gases, thus rendering impossible the granting of any legal monopoly upon the bare and broad idea of concentration by utilizing the buoyancy of air. Furthermore, the Supreme Court has often ruled, in cases discussed at page — of this brief, that patents for principles or laws of nature, separate and apart from the means by which those principles or laws are utilized cannot be sustained.

In the concluding paragraph of the opinion of the Supreme Court reference is made to the decision of the District Court in the Hyde case, which decision the Supreme Court reverses to the extent of declaring claims 9, 10 and 11 invalid. Claims 9, 10 and 11 define the amount of oil as "a small quantity." The claims sustained by the Supreme Court limit the amount of oil to a fraction of 1% by weight relative to the ore. In this finding the Supreme Court imposes a further limitation upon patent No. 835,120, confining that patent not only to a greater degree of agitation and the novel form of froth referred to by the court, but further restricting the patent to the use of a fraction of 1% of oil relative to

the ore. In this connection the court makes the following statement:

"As we have pointed out in this opinion, there were many investigators at work in this field to which the process in suit relates when the patentees came into it, and it was while engaged in study of prior kindred processes that their discovery was made. While the evidence in the case makes it clear that they discovered the final step, which converted experiment into solution, 'turned failure into success' (*The Barbed Wire Patent*, 143 U. S., 275), yet the investigations preceding were so informing that this final step was not a long one and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions' 'amounting to a fraction of one per cent on the ore,' and therefore the decree of this court will be that the patent is valid as to claims No. 1, 2, 3, 5, 6, 7, and 12, and that the defendant infringed these claims, but that it is invalid as to claims 9, 10, and 11."

MINE-WATER usually contains minerals in solution, the most common being calcium carbonate and the sulphate of magnesium, aluminum, iron, and copper. Other minerals are often present, but usually in less amount than either of those mentioned. The water of many mines is used for drinking and other domestic purposes, but there is always danger in such use of mine-water, particularly that from operating mines, due to the presence of organic matter that is far more harmful than any mineral the water may hold in solution. Generally, if the mine-water is unfit for domestic use its disagreeable taste will be a sufficient warning. Water issuing from veins containing a large amount of sulphide mineral is often heavily charged with the salts of iron and sometimes of copper, and it also occasionally contains some free sulphuric acid. There is little danger of anyone taking more than a single swallow of water of this description, as it is strongly astringent and often bitter and most disagreeable. In the early days of the development of the mines of Western Australia, the only water available for any use was that from the mine shafts and this was so salt—due to the presence of sodium chloride—that it had to be distilled and condensed before it could be utilized for steam-making, or for any other purpose. The minerals, in solution in water flowing from springs, or from veins, indicate the presence of these minerals in the rocks, or in the vein from which the water flows, but only the base metals, which on oxidation produce soluble sulphates, are likely to be detected in solution in water; neither gold, silver, zinc, nor lead will be found in such water by ordinary methods of analysis.

IRON ORE reserves of Spain are stated to be 700,000,000 tons of 50% ore. The province credited with the largest deposits is Leon, where there is 150,000,000 tons. Teruel has 135,000,000 tons, and Viscaya, 70,000,000 tons. About 9,000,000 tons has been mined annually during the past ten years.

Mining in Utah

By L. O. Howard

Official statistics having been duly published, it is of little interest to dwell long on the figures that show the remarkable record of Utah in 1916. It is more to the point to consider some of the possibilities of the present year by aid of these statistics. Utah occupies a unique position among the Western mining states in that it depends upon the base metals almost exclusively for its importance. While reaping the benefit of high prices for these metals, it has not had to meet the unfortunate situation peculiar to a State depending solely upon the precious metals. Cyanide-plants are notably absent. The use of expensive and scarce chemicals, such as cyanide and zinc-dust, is at a minimum. Although the production of gold and silver attained a respectable total in 1916, it nearly all came as a by-product from the ores of lead, copper, and zinc.

As an indication of the opinion that may be held by the smelting companies as to the immediate future of the mining industry may be cited the many improvements started during the past year and now in course of construction. Arrangements have been made to double the capacity of the copper-plant of the Garfield Smelting Co., which operated four blast-furnaces and five reverberatories in 1916, treating 3500 tons per day of metal-bearing charge. The capacity of the American Smelting & Refining Co.'s lead-plant at Murray is also to be increased. Six blast-furnaces were operated last year on ore from Utah, Colorado, Idaho, Nevada, and more distant States. The International plant at Tooele had the satisfaction of seeing its copper department busy for the first time since its erection, for it had four out of five reverberatories at work, treating 1500 tons of ore daily, thus slightly exceeding the capacity of its five lead-furnaces, which treated about 100 tons less, each day. Separate Cottrell plants are now treating the gases from the Dwight-Lloyd sintering-plant and the converters.

Operations of the United States Smelting, Refining & Mining Co. at Midvale, besides its electro-static and wet-concentrating mills and its 5-furnace lead-plant, now include the regular production of arsenic, electrolytic cadmium, and a small amount of thallium.

A number of new industries are getting into their stride and should increase Utah's production of unusual materials. Potash has attracted the most attention. Valuable salts are obtained from alunite at Marysville and from the brine of Great Salt lake. Marysville, which is in Piute county, at the southern terminus of the Sevier & San Pete branch of the Denver & Rio Grande railroad, has rapidly taken a position as one of the State's important and interesting districts. The Min-

eral Products Co. is in a position to produce 40 to 50 tons of potassium sulphate daily. The experimental stage has been successfully passed, and attention is now centred on the by-products. The possibilities with respect to these are most promising, and more interesting perhaps than the winning of the various valuable prod-

SKETCH SHOWING RAILROAD NEARLY COMPLETED FROM WENDOVER TO GOLD HILL, UTAH, AND AREA TRIBUTARY THERETO.

ucts from the brines of the Western lakes, as the former bear more resemblance to other mining and metallurgical industries.

The alunite as mined will average 35 to 37% Al_2O_3 and 10 to 12% K_2O . Alunite contains also 13% water and about 38% SO_3 . By 'roasting,' or, more properly, calcining, all of the water and three-quarters of the sulphur tri-oxide may be eliminated, leaving a calcined product amounting to a little less than 60% of the initial charge, and assaying about 18% K_2O and 61%

Al_2O_3 . The potash, expressed as sulphate, amounts to about 32%. Lixiviation with water will remove 90 to 95% of the potassium sulphate, leaving nearly pure alumina, for which uses will soon be developed. In fact, it is expected that during the current year this material will be utilized either in the manufacture of 'refractories,' for which it is especially adapted, or as a source of aluminum. I have it on good authority that some of this residue has been treated at Niagara Falls for the production of aluminum at a cost that would insure a profit under normal market conditions. This residue would make an unusually pure and high-grade ore of aluminum, and cannot be disregarded as a potential factor in aluminum production. The Florence Mining & Milling Co. has under construction a plant that should begin operations in the early summer. It is planned, I believe, to ship calcined alunite East for treatment. It is also distinctly possible that a market will be found for the calcined alunite without further treatment. Transportation rates exercise a controlling influence over metallurgical developments.

This year will also bring about a great extension in the productive area at Marysvale. Large deposits of alunite of lower grade have been found on the side of the Sevier valley opposite the producing mines, and we may expect to see the usual experience repeated—the continued extension of a mineral district much beyond the boundaries generally accepted.

Shipments of potash salts are being made also by the Utah Chemical Co. and the Salt Lake Chemical Co. with plants near Saltair and Grants on the shore of the Great Salt lake. The waters of the lake are the source of the potash, the Utah company taking the concentrated brine from the evaporating ponds of the Inland Salt company.

Marysvale has other claims to prominence as the shipping-point for a fair output of 45 to 50% manganese ore, which was forwarded to Illinois and Pennsylvania. A mill for treating antimony ore was built near Marysvale and is said to be turning out six tons of 50% concentrate daily. This is the only antimony property now in operation in the State, although a few tons of crude ore was shipped from near Brigham City, in Box Elder county, while high prices prevailed last spring. The present state of the antimony business does not encourage an increase in production, development, or prospecting.

There is certain to be a noteworthy output of sulphuric acid in 1917. The Garfield Chemical & Manufacturing Corporation has a 100-ton plant which ran a few days in December on gas from two Herreshoff roasters at the plant of the Garfield Smelting Co., but had difficulties owing to the extreme cold. A daily production of at least 150 tons of acid may be expected confidently later in the year.

This year will also see the inauguration of a hydro-metallurgical process for copper on a large scale. The Utah Copper Co. expects to have its sulphuric-acid leaching-plant in operation by July. A production of 10 to 15 tons per day of electrolytic spelter may be an-

ticipated soon from Park City, where the Judge Mining & Smelting Co. has completed its plant and begun to warm up its furnaces. The results of experiments with cathodes is awaited with great interest by metallurgists. Incidentally, Park City should have a record production in 1917. The Silver King Coalition has enlarged its mill. The Silver King Consolidated has leased and started the old Grasselli mill. Both of the large tailing-plants, the Big Four Exploration and Broadwater mills, have increased or are about to increase their capacity and will go into operation again as soon as the weather moderates.

The first full-year of milling on the American Fork is in sight, the Fissures Exploration Co. having started a 50-ton plant. The completion of a power-line into the district should result in maximum activity in 1917. The Alta district should have a good year, having received more adequate transportation facilities too late for the effect to be felt in 1916. In Big Cottonwood also a feasible method of hauling has finally been found in the use of motor-trucks and trailers. At present, however, the Cardiff is shipping about 100 tons per day on sleds, which, owing to the unusual snowfall of Christmas week and since, can haul into the smelter-yards without re-loading—a necessity in other winters.

Since the smelters have met the increased mine production with enlargements of plants, the congestion of last summer is not likely to be repeated, and the small producer of copper ore, to mention only the worst sufferer in 1916, will be able to market his ore and continue development on a scale impossible of realization in the past.

For many years the Deep Creek district in Tooele county has struggled against inadequate transportation facilities. Numerous projects for building a railroad into the district have budded but never blossomed, until the Deep Creek railroad has become a by-word. This year brings the realization of the 20-year old dream, for a road is now under construction from Wendover on the Western Pacific railroad to Goodwin, or Gold Hill, in the heart of the district. With its completion early this year will come the beginning of shipments from the large deposits of base metals of low grade, and the culmination of a boom now incipient.

Shipments from other scattered districts in Beaver county, and at Ophir and Stockton, will probably maintain the healthy rate of increase noted in 1916. As to the newer zinc districts that became prominent last year, there is an element of doubt. Large developed mines comparable with the newer ones of Idaho are lacking, and while an excellent profit was made considering the small amount of capital invested, most of the new zinc mines are not yet out of the stage where an abnormal market is an essential to successful exploitation. The cream has been skimmed and slow, plodding, and expensive development is now necessary to maintain these properties on the profit side of the ledger. It is to be feared that many of them have had balances recently 'in the red.'

At Tintic and Bingham it is not to be expected that the ratio of increase to past production—high on account of the cumulative acceleration of prosperity—will be maintained. Prices have undoubtedly reached a maximum, and wages also. Although the outlook is excellent for an abnormally prosperous year, there is a limit to possible growth, and long-continued acquaintance will bring out the faults of even our best friend. Friend Prosperity is being analyzed for his faults. His principal one, high cost of living, is just now receiving more attention than his greatest virtue, generally considered to be high wages.

Operations of the Utah Copper Co. and other companies in the Bingham district have received their due share of publicity, so that recapitulation of their successes is unnecessary. Extraordinary performances have become commonplace, and one record is hardly pegged before a new one is made. The severity of the winter will hinder operations and reduce the output for the beginning of the new year.

Although the position of the new mines that are exploiting carbonate of zinc is not as enviable as formerly, there will, without doubt, be an increase in the production of concentrate from sulphide ores. This will come principally from the increased capacity of Park City plants, both crude-ore and tailing-plants; from the operations on the old dumps in other parts of the State, for instance the Caldo mill treating the Horn Silver dumps at Frisco, where 200 tons is to be added to the 650-ton capacity now operating; a new flotation-plant of 300 tons capacity, which commenced operations late in the year on old dumps of the Midvale mill of the United States Smelting Co., and from the additional capacity of the United States electro-static and wet mill at Midvale.

The operation of a cyanide-plant in the Mercur district, is, I believe, the sole exception to the statement that precious metals are not won by direct methods in this State. In the West Dip area, the West Mercur Mines Co. has been operating a mill on the Old Daisy, or Norma, property. A relatively large deposit of medium-grade ore has been the cause of intermittent attempts at treatment for many years past, but no profit had been made for any continuous period, chiefly through lack of the capital necessary to permit economies in operation. The property is now in the hands of strong people and it is distinctly among the possibilities that Mercur will again appear as an important contributor to the State's output of gold.

In the rare-metal industry conditions are likely to become more stabilized. While there is little activity in the carnotite fields, the resumption of operations in Colorado on a large scale and the reported quotation of \$100 per ton for ore containing 2% U_3O_8 , may presage the resumption of mining for radium in Utah. The position of tungsten is likewise uncertain, although the present market allows profitable operation in some cases. I understand that there has been some development of molybdenite properties under the stimulus of high prices, but the undetermined technique of its metallurgy

has so far deterred operators from attempting extensive exploitation.

Had the coal companies been on the 'leak list' of the weather man, their profits could have been greatly increased, but just now the same factors that have caused the excessive demand have operated to curtail output. The farmer's maxim could well be adapted to read, "Mine (and ship) coal while the sun shines."

Hydrocarbons have had a varied career, but profit is mostly among the things to be. Ozokerite received its due share of attention early in the year and one mill commenced treatment. Recently there has been more secrecy as to operations, and I am not informed as to progress. This may be only business policy, or may indicate that the industry has not been so satisfactory as may have been anticipated. One or two small companies have been organized to develop the oil-shale of north-eastern Utah, but details have not been made public. It is a fact recognized by the well-informed that the successful exploitation of this resource is only possible on a large scale. The amount of this shale is so large and the reported content of lighter constituents so great that its possible effect in ameliorating the scarcity of gasoline is a thing to be considered. The possibilities have been known for a long time, and it appears that the utilization of this source of oil is near at hand.

Gasoline Cautions

Gasoline should be kept and used only in small quantities, and used only by experienced employees who realize the danger in using this volatile fluid and know how to handle it safely, says the *Compressed Air Magazine*. Gasoline should be handled in small safety-cans, equipped with safety-gauze and safety-stopper. Gasoline is exceedingly volatile and will vaporize when exposed to the air at any temperature down to 15° below zero. This vapor is nearly three times as heavy as air, and when mixed with the proper quantity of air becomes violently explosive. The vapor will ignite from any open flame, even from a spark of static electricity from a human body, a spark from an emery wheel, or from a sufficiently heated surface. The gasoline vapor, being heavier than air, will naturally seek a lower level, and if confined where there is poor ventilation, will sometimes remain in an explosive condition for months.

TIN RECOVERED by the Tongkah Harbor company, operating at Puket, Siam, during the year ended September 30, 1916, amounted to 1077 tons of 73.1% metal-content. Five dredges dug a total of 3,363,750 cu. yd., equal to 107.65 yd. per hour each. The boats worked 72.35 to 83.86% of the total possible time. The ground yielded 0.717 lb. of tin oxide per cubic yard., equal to 16.4 cents. The cost of operation was 8.12 cents, and other charges 1.15 cents. From the year's profit and previous balance four dividends were paid totaling \$290,000.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

SEATTLE, WASHINGTON

PROCEEDINGS AT OPENING OF NEW EXPERIMENT STATION.

Recently there was opened on the campus of the University of Washington, by the U. S. Bureau of Mines, a Mining and Metallurgical Experiment Station, and to celebrate this event the College of Mines of the University held a smoker and open house on the evening of January 12. With this celebration was combined the annual social gathering to welcome the 'shorthorns,' namely the men taking the winter short-course, which is held every year for the particular benefit of prospectors, miners, and others desirous of attending this class of instruction and elementary practice in the laboratory and mill and mining machinery rooms of the College. There were 202

Ellis, Susitna; John D. Leedy, Nome; C. C. Mooers, Seward; H. L. Polson, Ketchikan; E. S. Robe, Knik; C. Simenstad, Valdez, and D. A. Winn, Juneau.

Among those from the United States, not already mentioned, were J. W. Bullock, manager Amador mine, California; F. R. Field, Denver, Colorado; Rufus Buck, Montana; J. T. Gregg, Portland, Oregon; Tom Brown, Sumas, Washington; and the following from Seattle and district—J. L. McPherson of the Alaska Bureau of the Seattle Chamber of Commerce; W. H. Whittier, Fellow of the Industrial Bureau; L. D. Jones, superintendent of Renton Mines; W. E. McMicken, of the Hyde Coal Co.; J. P. Fuller, editor of the *Pacific Builder and Engineer*; H. P. Fogh, Seattle, and many others. From Canada came C. E. Lewis, Dawson, Yukon territory;

MINES BUILDING, UNIVERSITY OF WASHINGTON, SEATTLE, MENTIONED IN THIS LETTER.

U. S. BUREAU OF MINES, PACIFIC NORTH-WEST STATION, UNIVERSITY OF WASHINGTON, SEATTLE.

in attendance, exclusive of 50 to 60 men who had been attending a press convention held at the University the same night, and who put in an appearance late in the evening. The following names, constituting about one-third of those present, will give an idea of the representative nature of the gathering:

U. S. Bureau of Mines local staff: Dorsey A. Lyon, superintendent of the Experiment Station; G. Watkin Evans, mining engineer; U. B. White, chief clerk; A. M. Felton, and J. J. Corey in charge of the Mine-Rescue Station established here by the U. S. Bureau of Mines in 1910.

University of Washington: Regents Miller Winlock, Seattle, and John A. Rea, Tacoma; president Henry Suzzallo; College of Mines: Milnor Roberts, dean; Joseph Daniels, professor of mining engineering; C. R. Corey, professor of metallurgy; J. L. McAllen, instructor in mining engineering; H. L. Glenn (of the U. S. Assay Office, Seattle) and F. Powell, lecturers. University Mining Society: Jesse Johnson, chairman, and H. G. Boulton, secretary.

A. I. M. E., Seattle Section: C. E. Bogardus, Mel C. Butler, Donald G. Campbell, Glenville A. Collins, Jas. A. Kelly, Chester F. Lee, H. L. Manley, Chas. A. Newhall, Carl H. Reeves, F. H. Richardson, Geo. Rockefeller, Amos Slater, and others.

Other engineers: J. E. Blackwell, Marcel Daly, Glen Dunbar, W. C. Dunbar, C. E. Hill, D. E. Hooker, L. G. Knight, E. A. Loew, J. R. Morrison, R. H. Ober, Capt. A. O. Powell, W. H. Tiedeman, A. L. Valentine, Percy Wright, and many more.

Alaska was represented by A. C. Baldwin, Valdez; M. A.

E. N. Dally, of the Flathead oil country in South-east Kootenay, B. C.; T. M. Daulton, manager of the Placer Mines Co., Atlin, B. C.; Nicol Thompson, president of the Board of Trade of Vancouver, B. C., and E. Jacobs, secretary of the Western Branch of the Canadian Mining Institute, Victoria, B. C.

After a student's orchestra had rendered instrumental selections, there were several addresses, as follows:

The president, Henry Suzzallo said: "On behalf of the University administration I desire to welcome the practical miners, and the friends of the mining industry, to this Mines' Experimental Station, established by the Federal Government in co-operation with the University of Washington. The occasion marks the return of practical men to the training class of the College of Mines, and the opening of an establishment devoted to that practical research work in which the true teacher of mining is ever interested. * * * We are glad to have this work in practical research as a Campus institution associated with our research work in mining and other engineering fields. We bid you welcome to this winter of study in the short courses. We trust that you will profit greatly and at the end return to the practical field of operation to make that fortune to which every world-trained and hard-working miner is entitled."

Dorsey A. Lyon gave information relative to the U. S. Bureau of Mines, its work, and the purposes for which its experiment stations have been established, saying:

"When the Bureau was organized it took over the work of the Technological Branch of the U. S. Geological Survey.

Under a subsequent Act, Congress specifically stated that the work of the Bureau should be (1) the preservation of the health and life of the miner, and (2) the prevention of mineral waste. All the work the Bureau does has either the one or the other of these objects in view. The work of the Bureau has gradually expanded since its organization. The first Bureau station was established at Pittsburg, Pa.; later on stations were established at, respectively, Urbana, Illinois; Denver, Colorado; San Francisco, California; and Salt Lake City, Utah. The work carried on at these several stations is as follows: Pittsburg: coal-testing, testing of explosives, studying mine explosions in the experimental mine, mine-rescue work, study of mine gases, etc. Urbana: study of coals with particular reference to their utilization for fuel and steaming purposes. Denver: study of the recovery of precious metals and their utilization. San Francisco: study of smelter-smoke gases with the purpose of preventing damage, and the recovery and utilization of the volatilized products contained in them. Salt Lake City: study of the low-grade and complex ores which are either too low-grade or too complex to be profitably worked at the present time and hence are liable to be wasted in the mining and treatment of ores that can be mined and treated at a profit. In 1915 Congress authorized the establishment of 10 additional Bureau of Mines' stations, no more than three of which should be established in any one year. In accordance with the provisions of that Act, Congress in 1916 made the money appropriations requisite for the establishment of three stations, the choice of positions for which was left to the Secretary of the Interior, who afterward decided that these stations should be respectively, at Tucson, Arizona; Fairbanks, Alaska, and Seattle, Washington.

"Work at Seattle Station"—The work it is proposed to do at the Mining and Metallurgical Experiment Station includes:

(1) Determining how far it may be profitable, and likewise feasible, to use electricity in the recovery of metals from their ores, by (a) electro-thermic processes and (b) electrolytic processes.

(2) Study of the coals of the North-west, and of the west and south-west coast of Alaska, for the purpose of (a) determining how they may be mined with the least possible waste, and (b) the beneficiation of low-grade coals so as to render them suitable for fuels for all purposes.

(3) Study of the problems connected with the ores of the North-west, and of the west and south-west coast of Alaska, in so far as such problems may differ from those now being studied at other stations of the Bureau."

E. Jacobs, of Victoria, B. C., brought greeting from the Western Branch of the Canadian Mining Institute, and expressed gratification at the inauguration, under Federal Government auspices, of an extension of the scope of the mining and metallurgical educational work so long and so zealously and effectively carried on by the College of Mines of the University of Washington. In passing he mentioned that the estimated approximate value of the mineral production of British Columbia in 1916 had been \$45,000,000, in the proportion of \$35,000,000 for metalliferous minerals, \$8,500,000 for coal and coke, and \$1,500,000 for miscellaneous products. This compared with \$32,440,000 in 1912, the year of previous highest record. The most striking feature of the year was the establishment of electrolytic refineries for copper and zinc, so that as a result of these and earlier achievements at Trail, B. C., the Consolidated Mining & Smelting Co. is now producing there five refined metals, namely, gold, silver, lead, copper, and zinc, a result stated to be unequaled in the world.

Geo. Watkin Evans gave an outline of the work it is proposed to do at the Experiment Station in connection with coal.

J. J. Corey, told of the opening of the Mine-Rescue Training Station on the University Campus nearly seven years ago, and of its useful work done during the intervening years to date. Approximately 900 had been trained in mine-rescue work and first-aid to the injured—401 in mine-rescue work

and about 500 in first-aid. With the exception of 75 to 80 trained by officials connected with Bureau Railway Car No. 5, stationed at Billings, Montana, which had made two trips in the State of Washington, all these had received their training at the local station. All University students taking the mining course are required to take the mine-rescue and first-aid training before graduating. Recently there had been added to the equipment of the station Mine-Rescue Truck No. 3, built by the White Motor Truck Co. of Cleveland, Ohio, with body of a special design of the Bureau of Mines. This motor is of 45 hp. and in an emergency the truck can travel at a speed up to 50 miles an hour, carrying a rescue-crew of five men, with all mine-rescue and first-aid equipment and reserve tanks of oxygen and all other necessary supplies.

DEADWOOD, SOUTH DAKOTA

METAL OUTPUT.—POWER EXTENSIONS.—ORO HONDO DEVELOPMENT.

The production of gold in the Black Hills of South Dakota during 1916, amounting to \$7,500,000, has been exceeded only once in the history of the region. Tungsten was second in value, namely, \$500,000, a record output. Silver, with 212,000 oz. valued at \$140,000, was also the largest in years. While 1916 was a highly prosperous year, much is planned for 1917, and it promises to be the banner year.

So far the biggest single undertaking announced, is the construction by the Homestake company of a second hydro-electric plant on the Spearfish river. Late last fall the company purchased the Cascade placer, covering 6 miles of the stream, and adjoining the upper end of the project which was successfully completed some years ago. Construction work on the new plant will start soon; in fact bids have been submitted for the tunnel work, and as soon as the contracts are signed ground will be broken. The water for the new plant will be carried in wood-stave pipe except for one mile, where the canyon cliffs are exceptionally rugged and a tunnel will be used as a conduit. In all the water will be carried five miles, delivered under a 600-ft. head and will develop 3000 hp. Endeavor will be made to complete this project within the year. New installation at the Homestake re-grinding plant is proceeding at a satisfactory rate. Here three 5 by 14-ft. tube-mills are being added to the three tubes and one Hardinge mill already in use. Two Dorr simplex classifiers and additional amalgamating tables are being put in place.

The recent purchase by John T. Milliken, of St. Louis, of the Montezuma and Whizzers property, comprising 150 acres, is taken to indicate that he is satisfied with results of exploration at the Oro Hondo, where he has spent \$250,000 during the past two years in exploiting the southerly extension of the Homestake ore formation. A policy of strict secrecy regarding developments in this property has been maintained ever since work was started, so that nothing definite is known regarding disclosures underground. It is known that the shaft is 2000 ft. deep, and that much lateral work and two miles of diamond-drilling have been done from it. Four diamond-drills have been constantly employed for months. It is also generally known that he contemplates sinking the shaft 1500 ft. deeper. This would call for an almost complete re-modeling and replacement of the surface plant. A new engine and head-frame would be required for such additional depth. It is argued that he would scarcely be justified in making these expenditures unless he had found ore, as it is believed that exploration has already penetrated ground where ore should be found, if it continues into the property. The Montezuma and Whizzers adjoins the Homestake on the east, and runs to the western city limits of Deadwood. It covers the locally-called 'big iron dike,' the strongest and most persistent vein outcrop in the Black Hills. It can be traced on the surface for over four miles across hills and gulches. On both the north and the south it is hidden beneath sedimentaries. This vein has never been prospected for more than a few feet below water-level.

JOHANNESBURG, TRANSVAAL

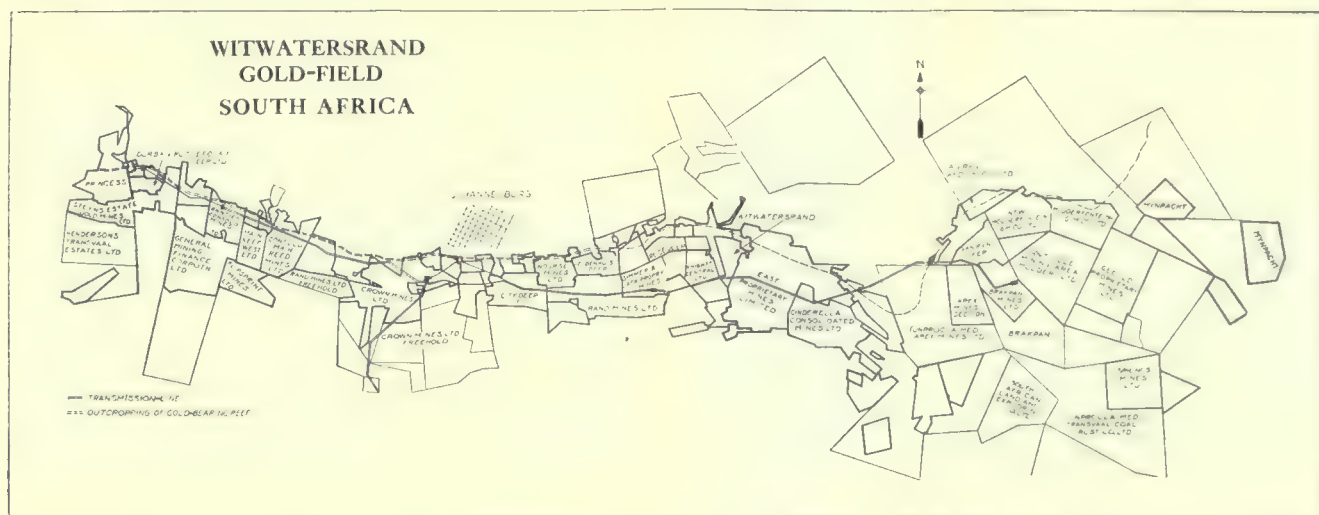

GOLD OUTPUT.—UNDERGROUND DIFFICULTIES.—RAPID SHAFT-SINKING.—FAR EAST RAND.—THE BIG COMPANIES.

It seems opportune at this season (December) of the year to reflect on the doings and achievements of 1916. The production of gold is estimated at 8,972,000 fine ounces, valued at £38,110,000. These figures indicate that the Rand will again pass the previous record which was 8,771,919 oz. worth £37,260,746 in 1915. The quantity sent to the mills is estimated at 28,652,000, against 28,355,175 tons in 1915. This indicates a slight improvement in the grade of ore treated, but as working costs were higher and considerable expense was incurred in connection with the War the estimated profits for the year are appreciably lower.

A feature of 1916 were the increasing difficulties in mining, encountered as greater depths were reached. Several mines on the Rand are now working from 4000 ft. to upward of 5000 ft., at which depths it becomes useless to depend on pillars for supporting the hanging wall, even though they be of larger dimensions. All kinds of packs have been tried,

This explains why several shafts sunk on the Far East Rand have encountered unpayable reef, and afterwards by driving along the contact have found milling ore. The Brakpan mine is a striking example of this. This discovery by Mr. Mellor shows that only one-half of the 90,000 claims on the Far East Rand can be regarded as profitable.

Several attempts were made to lease some of the mining ground owned by the Government. Its desire was to extract a large share of profits, while the lessees took all the risk. This prevented any business being done. However, in August, two properties were offered on lease with easier terms for those who tendered, and these were taken by the Central Mining & Investment Corporation, and the Consolidated Mines Selection Co. In both cases the successful tenderers control adjoining properties, with which it is intended to work the new areas. New mining legislation to empower the Government to deal with these Far East Rand properties was also under consideration by Parliament, when an agitation was raised in favor of the Government developing the region by means of State mines. The agitation spread until the Government deemed it expedient to appoint a Commission to enquire

even reinforced concrete supports, but these afford only temporary relief. The only effective support is to take out all of the pillars and completely fill the cavity with sand. Hence the practice of sand-filling is expanding on the Rand each year. During 1916 there were fewer earth tremors than formerly, and probably sand-filling may be credited with this change. The report on earth tremors by the Government Commission made its appearance during the year, the conclusion arrived at being that the shocks were entirely due to mining. Larger pillars and their quicker extraction were recommended, mining without leaving pillars was considered impracticable, and more extensive sand-filling was recommended. Seeing that preparations for mining at depths over 6000 ft. are being made, some method of mining without leaving pillars will have to be adopted in the future.

Another feature of 1916 was the sinking of the Crown Mines No. 14 circular shaft 252 ft. in one month. This was considered a world's record for rapid shaft-sinking. The diameter is 20 ft., and the shaft is being sunk for ventilation purposes.

The Far East Rand attracted more attention locally during 1916 than the remainder of the Rand. The discovery made by E. T. Mellor of the Geological Survey that the 'reef' on the Far East Rand occurs for the most part in elongated, parallel 'patches' or lenses, with the long axis running roughly south-south-east, attracted considerable attention at the time. Between these elongated patches occur areas frequently barren of profitable ore and sometimes the hanging and foot-walls come together. This occurrence is described as a 'barren contact.'

into and report on the matter. At present (early in December) the Commission is busily occupied taking evidence. During 1916 an attempt was made to induce American capital to come in to develop this territory, and visits were paid by Messrs. Mein and Hoffman on behalf of New York people, but nothing has come of the matter so far.

None of the great consolidated properties on the Rand met with the success expected during 1916. The Randfontein Central has at last got its 1000-stamp mill at work, but for some time has not been able to pay a dividend. The Crown Mines, with the object of making more profits, reduced the stoping widths with generally disastrous results, and has again resorted to the previous method. While these experiments were in full swing the Randfontein gold output exceeded that of the Crown, then the leading producer here. At the East Rand Proprietary Mines the western section of the property proved much broken below the water dike, current development became unsatisfactory, and it looks as though the property will become a 'white elephant.' It was decided to spend £200,000 to test the reef by cross-cutting and shaft-sinking at a depth of 6000 ft., but it cannot be said that the prospects of the reef becoming profitable at depth are encouraging. The Crown Mines has proved the Main Reef series south of the South Rand dike by boring, the results as far as can be ascertained by boring being satisfactory. The leading mines in the Barberton and Lydenburg districts have also done poorly during the year. Seven companies averaged a total of 52,000 tons for 28,000 oz., and a profit of \$120,000 per month.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU. On January 27 three large snowslides near Juneau killed two men, carried away power flumes and other mining property, and forced the Alaska Gastineau mine and mill to suspend work.

ARIZONA

In Bulletin No. 44, economic series No. 12, J. Preston Jones of the State Bureau of Mines, covers workmen's compensation. Part I deals with definitions, theories, development, constitutional obstacles, and brief digest of the compensation acts of the United States. Part II discusses the law as applied in Arizona, where it seems to compare favorably with those of most of the other States of the Union.

CHLORIDE. The Jesse Knight syndicate of Salt Lake City has purchased four claims and a fraction in the centre of this district, and will operate under the name of the Bullion Hill Mines Co. A shaft is to be sunk 800 ft., and machinery is to be purchased.

GLOBE. According to A. H. Buckingham of the Globe Commercial Copper Co. the manganese deposit opened by him and W. Wright has widened from 4 to 12 ft. Each miner can break 4 tons per day. The ore returns 38 to 40%. The company is financing operations, also the installation of a concentrator.

OATMAN. An examination of the Gold Ore mine for Moline, Illinois, people has been finished by H. Irving Jones. The reason of this was to determine the size of mill that the company proposed to build at once. Last year there was treated 2000 tons of ore at the Gold Road mill, and the same process as used there will be adopted.

The Fessenden Gold Mining Co. having sold treasury shares, will resume work at once. The property has a vein that parallels the United Eastern. A shaft was sunk 540 ft., and a cross-cut driven to the vein on the 500-ft. level.

The east drift on the 300-ft. level of the Murdock, which has cut several shoots of good ore, encountered soft ground and was turned into the hanging wall where it is proceeding in a silicified rhyolite, containing specks of hematite which pan well. The vein is on a rhyolite-granite contact, the only contact vein yet opened in the district, and was reached after cross-cutting 62 ft. of silicified rhyolite, which in places carries fair gold-content. The large producing mines of the district are found in a green-stained chloritic-andesite, but rhyolite predominates in the Black Range section, in which is the Murdock. J. Parke Channing is developing the Oatman Syndicate between the Murdock and the Nellie. The Nellie vein is wide, and contains considerable ore of milling grade on the 350-ft. level, where driving is in progress.

The Lucky Boy, south-east of the Aztec workings of the Tom Reed, is cutting a station at 400 ft. preparatory to cross-cutting to the main vein, which is 50 ft. wide on the surface.

The Adams, in the Black Range, is in the vein-casing in the cross-cut at the 400-ft. level and has cut 15 in. of talc in one of the characteristic slips. A steel bulkhead has been set in concrete as a provision against a heavy flow of water. The cross-cut was driven at a point between two ore-shoots that were developed on the surface, and some driving probably will be necessary to get into the ore.

The United Eastern mill has been in constant operation since it started on January 4, and will make the first clean-up in a few days.

PARKER. Extensive development is the order of the day in this district. The producers are shipping from 20 to 250 tons per day each, the Swansea being the largest. Results at the Revenue are encouraging, while across the river the Copper Basin is attracting much attention.

PRESCOTT. In the Big Bug district the Big Ledge Extension company is to do considerable work on its copper claims. A hoist of 1000-ft. capacity is to be installed.

ARKANSAS

According to J. H. Hand of Yellville, official recorder for the Arkansas Bureau of Mines, northern mines produced 34,086,500 lb. of calamine, 2,562,000 lb. of blende, and 321,000 lb. of lead during 1916. The total is an increase of 144% over that of 1915. The Rush district yielded over 50% of the total; Zinc contributed 15%.

CALIFORNIA

CARRVILLE. The Estabrook dredge at Trinity Center sprang a leak on the night of January 15 and sank in 30 minutes. Efforts will be made to raise the boat, the chances for doing so being considered good, as it was digging in shallow ground. The boat was built in 1911 by the Alta Bert Gold Dredging Co., and had been in commission just five years.

On the 23rd the dredge had been raised and work is being rushed to get it in working order again.

(Special Correspondence.)—The Indian Valley railroad has been completed to Crescent Mills, and the Engels Copper Co. is now shipping from this point instead of Keddie, saving a haul of 11 miles. The line is expected to reach the mine in a few weeks, and it is reported that a branch may be extended into the Genesee district, at present claiming much attention from prominent mining operators. At the Engels property much new work is going on, and plans have been prepared for a 2000-ton flotation plant, of which the first 500-ton unit is scheduled to go into service before July 1.

The International Smelting Co., operating the Walker mine near Portola, has taken under option the Green Ledge and Tutt properties. These mines were worked for their gold ores years ago, and the copper-bearing material neglected. Under the new management the promising copper deposits will be given most attention. Developments at the Walker mine continues satisfactory, despite deep snow. The flotation plant is treating 75 tons of ore daily, and concentrate is shipped to the Tooele smelter of the International company. V. S. Hart is manager.

The U. S. Smelting, Refining & Mining Co. has ordered a large compressor and machine-drills for the Five Bears property, lately taken under bond. The east cross-cut, from a point in the adit about 1300 ft. from the portal, has opened a 15-ft. vein of chalcopryrite. The company is also preparing for comprehensive work at the Iron Dyke, Eagle Hill, and other mines.

The Copper Mountain-Summit group of 36 claims is being developed by H. L. Huston and others of San Francisco. The ore so far opened is chalcocite, with some gold and silver. From the Copper Mountain ore was shipped to Swansea, Wales, in 1864. The Reward and Blue Bell groups, shippers during the Civil War, have been taken under bond by San Francisco people.

The building of the Indian Valley railroad has infused new life into the region, and many old mines have been re-opened,

and numerous prospects are being worked. While the copper deposits claim paramount interest, several gold claims are undergoing development.

Crescent Mills, January 24.

HIGHGRADE. This district in Modoc county attracted a good share of attention in 1912 in both California and Colorado. The district lies on both sides of the California-Oregon State line, and six to seven miles east of Goose Lake valley. The rocks of the region all are volcanic, the ore, which is gold-bearing, occurs in flow-rhyolite and in rhyolite-tuff. Some high-grade ore has been shipped and a large amount of low-grade ore has been developed in the numerous mines. Pyrite and arseno-pyrite are the principal sulphide minerals in the ore, and gold can occasionally be seen. Highgrade is a dis-

HESS MINE, MODOC COUNTY, CALIFORNIA.

trict possessing the elements of success, but by far the greater part of the ore must be treated in reduction plants built at the mines, or at least, in the district, as it is too low-grade for shipment to distant points. Wood and water are obtainable in sufficient amount for both mining and metallurgical purposes, but development has been slow, principally owing to a lack of sufficient capital properly to finance the concerns operating there.

(Special Correspondence.)—Central Eureka shareholders have just received the following report on December operations: Ore treated, 2890 tons, yielding \$3239 in bullion and \$5180 in 74 tons of concentrates. From sundry sources the company derived \$238 and there was collected during the month on account of assessment No. 39, \$4,708, making a total of \$13,365. The company spent \$15,204, of which mining and development work cost \$9653; shaft-sinking, \$2210; pumping, \$364; milling, \$1181, while salaries, insurance, attorneys' fees, and sundry expenses make up the remainder. In addition to the shaft work, the 1800-ft. west foot-wall cross-cut was advanced 30 ft., the face now being in mixed quartz and greenstone. Assessment No. 40 of 3c. per share has been levied to meet current expenses, including the installation of a new steel cable.

Sutter Creek, January 23.

COLORADO

ASPEN. This district is watching progress of the Hope tunnel, as it will benefit all in several ways. Mostly local money is in the work. In 1916 the adit was advanced 1200 ft. Indications at present point to ore being near.

BOULDER. The Nederland tungsten area is having a busy winter, with good production. The Primos, Wolf-Tongue, Vasco, Degge-Clark, and Boulder companies are all extracting ore.

CRIPPLE CREEK. It has been decided not to extend the Roosevelt drainage-tunnel to the Golden Cycle shaft, but end it near the shaft of the Portland, which is 1200 ft. ahead.

GEORGETOWN. Ore containing coarse gold has been opened by McCluskey & Convery in their lease in the Capital mine.

This is near the rich ore found in September by Hanson & Walthers. Other lessees are doing satisfactorily.

RICO. In the main lower adit of the Rico Argentine, which is in 800 ft., and a depth of 1000 ft., shows 12 ft. of ore assaying 4% copper, 15 to 20 oz. silver, and 15% lead. The zinc-content has disappeared. The shoot has been opened 75 ft., and daily shipments are 25 tons. In the spring an 800-ft. tram is to be constructed, and shipments will be increased to 100 tons.

TELLURIDE. The operating statement of the Colorado-Superior Mining Co., owner of the Black Bear mine, for the fiscal year ended September 30, 1916, shows total receipts from ore sales and boarding-house profit of \$259,324, while the total expenses amounted to \$191,664. The net operating profit was \$67,660. During the period 48,450 tons of dry ore was milled, out of which 3506 oz. of gold bullion, 1888 tons of lead concentrate, and 4660 tons of zinc concentrate were obtained. The total operating cost per ton of ore milled, including development and new construction, was \$3.956. Development amounted to 1467 feet.

IDAHO

KELLOGG. In the Pine Creek district the Hilarity and Pine Creek M. & M. companies have been consolidated. This arrangement is of importance, and will result in economic operations.

PORTRHILL. The Idaho-Continental mine, which is 26 miles from rail and 3700 ft. higher than the line, shipped 1875 tons of concentrate from August 15 to January 18. About \$31,000 net is expected from the sale. The mill is working well, flotation units are to be added, and 1000 tons of concentrate monthly is expected when running full time. Mining is done by caving.

WALLACE. For the sum of \$150,000 the transfer of the Frisco mill and concentrator from the Federal Mining & Smelting Co. to the Tamarack & Custer Consolidated Mining Co. was completed on January 16. Besides the concentrator, machinery, water-rights, flumes, penstocks, and right-of-way, the deed conveys approximately 40 acres of the surface ground of various lodes and millsites adjoining the concentrator. The Federal company reserves the ores and minerals beneath the surface and the right to mine and extract the same.

MICHIGAN

HOUGHTON. In spite of cold weather the copper mines in January should make nearly a record output. 'Baby' drills are proving a success in some of the mines, especially in the Ahmeek, which has 35, and the Copper Range mines, which have 135. Calumet & Hecla is trying an improved type of electric-haulage system. The Quincy has completed extracting one of the largest pieces of 'mass' copper ever mined in the district. On No. 70 level the metal was first found, and its length was 78 ft., ranging from 6 to 30 inches in width.

MISSOURI

JOPLIN. Prices for zinc ore rose \$11 per ton last week, the range being from \$70 to \$86. The weather is generally favorable for a steady output. The Missouri-Kansas-Oklahoma region produced 8472 tons of blende, 287 tons of calamine, and 1186 tons of lead, averaging \$76, \$44, and \$90 per ton, respectively. The total value was \$766,550.

MONTANA

BUTTE. It is reported at Boston that at a depth of 2300 ft. the Anaconda company has cut ore in the Leonard mine 50 ft. wide, averaging 5%. Part of the vein assays 7% copper, while some of it is as low as 2%. The entire orebody is of commercial grade. Another body being opened on the same level between the Leonard and Tramway mines promises to be equally good and even larger, as at one place it is 150 ft.

wide and at another point 100 ft. This ore averages 31% copper.

Telegraphic advice states that the Butte & Superior shaft has been damaged by fire, but details are not available yet.

TAOS. The Snowstorm Mines Consolidated report for the period April 15 to December 31, 1916, states that the expenditure on construction was \$470,548. From \$50,000 to \$75,000 will be required to complete the work in hand. The new mill is expected to be ready in February.

NEVADA

According to the State mine inspector, A. J. Stimson, there were 5800 men employed in Nevada mines last year. White Pine county leads with 1213 men, Nye second with 1072, Churchill 235, Clark 494, Douglas 4, Elko 380, Esmeralda 767, Eureka 55, Humboldt 294, Lander 127, Lincoln 168, Lyon 264, Mineral 428, Storey 235, and Washoe 64. There were 29 fatalities.

(Special Correspondence.)—The Charleston Hill property has been taken under an eight-year lease by Clark & Clough of Butte, and preparations outlined for the sinking of a shaft at the north end. This is on ground adjoining the National mine.

At the National group, sinking in the foot-wall of the National vein is proceeding, and within 60 days a cross-cut will be started to open the orebody at considerable depth below the present workings.

A lease has been taken on the Chee Foo lode by N. P. R. Hatch, president of the well-known Hatch lease in the Buckskin district. The Chee Foo vein passes through Auto hill, where the first high-grade ore of this place was found, and is well defined. Silver predominates. It is the intention of the Hatch people to sink on the vein.

Work has been resumed on the Last Chance, White Rock, and Equator properties. A large interest in the Equator has been secured by J. S. Miller of Butte, and vigorous developments decided on. At the White Rock, J. L. Workman has started driving of the adit an additional 100 ft. on the Wheeler-Murphy vein.

National, January 25.

(Special Correspondence.)—The first sulphide ore to be found in the Rand district has been encountered at a depth of 320 ft. in the Queen Regent mine. The ore contains copper, gold, and silver, occurring in a contact of andesite and rhyolite. The company is opening free-milling ore of good grade near this point.

The shaft of the Nevada Rand Mines Co. is being sunk a depth of 500 ft.; it is now down 300 ft. The property was recently inspected by C. R. Murdock. Philadelphia people are largely interested.

Much new work is going forward in the Gold Pen. At a depth of 260 ft., the bottom level, the vein is 36 ft. wide with a 5-ft. shoot averaging \$19 gold per ton. A 4-ft. vein of \$50 ore was lately found in the western part of the mine, and is being developed.

Rand, January 25.

ROCHESTER. It has been officially announced that L. A. Friedman has acquired 71 claims from 54 people, covering the whole vein system of the district, between the Rochester Mines and Nevada Packard properties. The cost was \$350,000, for over 800 acres. A 600-ton mill is proposed. The Rochester Combined Mines Co. has been formed to operate the ground. J. W. Wilkey is to be superintendent.

THOMSON. Owing to slow delivery of coke the Mason Valley smelter's start is being delayed. To prevent interruption to smelting, 2000 tons of coke is to be accumulated. Two furnaces will reduce 1000 tons daily, which should benefit the region considerably.

TONOPAH. Last week's output from the district was 9266 tons valued at \$166,788.—The Belmont shipped 138,886 oz. of

bullion worth nearly \$1 per oz. During December the Extension treated 8203 tons of ore for 142,510 oz. bullion, and a profit of \$51,220.—Good progress is reported on No. 6 and 7 levels of the Jim Butler.

NEW MEXICO

(Special Correspondence.)—The last two weeks' clean-up on the Mogollon Mines Co. amounted to 15,226 oz. of bullion and three tons of concentrate, from 2450 tons of ore. Ore-pockets are being completed on the 900-ft. level, and regular production will be handled through the new three-compartment shaft by the last of January.

A contract has been let by the Oaks Company at the McKinley in its main adit in Mineral creek. This is opening the Queen vein at the lowest point along several miles of strong outcrops. A larger amount of development is now being done on the Queen at various places than at any time.

During the past two weeks work in the Gold Dust has included cross-cuts into the foot-wall at two or more places, and the vein is shown to be wider than at first supposed. This development is in the main adit, now in over 1000 feet.

Mogollon, January 16.

SANTA RITA. 'Prospecting and Mining of Copper Ore at Santa Rita, New Mexico,' is the title of Bulletin 107, just issued by the U. S. Bureau of Mines, in co-operation with the U. S. Geological Survey. This bulletin describes the situation and general geography of the Santa Rita district, the ore deposits, the adaptation of mining methods to geology and topography, prospecting and locating orebodies, churn-drilling and sampling, assay-records and ore classifications, and the general methods of mining in this district, by the Chino Copper Co. The authors are Donald F. MacDonald and Charles Enzian.

TEXAS

The U. S. Geological Survey is continuing the exploration for potash by drilling in north-western Texas, in the saline deposits of the red-bed formations. This project has been under consideration from the beginning of the potash investigations, and data bearing on the distribution and character of the red-bed salines have been gradually accumulated. On the suspension of the Survey's drilling operations in the Nevada desert basins in the fall of 1915, the equipment was at once moved to Texas and a start made on the boring there. The site of this boring is in Potter county at Cliffside, a minor station on the Fort Worth & Denver City Railroad, 6 miles north-west of Amarillo. The equipment was delivered in November and drilling commenced December 16, 1915. This work was carried on continuously until February 29, 1916, when, owing to the practical exhaustion of the drilling fund, it had to be stopped. The well was then 363 ft. deep. The upper part was cased with 168 ft. of 10-in. pipe, and the lower part was a 6-in. hole without casing. In July, 1916, the new appropriation for Geological Survey work made funds available to carry on the drilling, and steps were at once taken to resume. At this time, however, steel and machinery plants were overloaded with orders, and delay in the delivery of necessary equipment prevented starting the work until November. Since November 7 the work has gone on continuously. Most of the time has been consumed in re-drilling the hole where it had caved below the casing formerly set, and in underreaming and setting a new string of 8-in. casing to the original depth of the hole, 363 ft. On January 1, 1917, drilling in new ground had reached a depth of 386 feet.

(Special Correspondence.)—The West Texas Graphite Co. has been placed in the hands of receiver by Judge Duval West of the Federal District Court at Austin upon application of Albert C. Burrage and Ralph Arnold. Walter Bremond of Austin was appointed receiver. The company is composed of Californians. It began the development of a large deposit of graphite near Burnet, 30 miles from Austin, about a year ago,

and has expended more than \$50,000 in plant, etc. The company recently made its first shipment of a carload of the graphite and is now prepared, it is said, to ship regularly. Its inability to meet quickly maturing indebtedness brought about the receivership.

Austin, January 20.

EL PASO. Records of the U. S. custom house here for 1916 show that a total of \$2,389,459 of gold and silver ores and bullion and lead, zinc, and copper ores were exported from Mexico through this 'port' of entry. This was a falling off of nearly 50% in the value of metals shipped into the United States through El Paso as compared with 1915. There was an increase in 1916 of 6585 tons of lead ore, worth \$64,574, over the exports of ore for the preceding year.

UTAH

The State School of Mines, the Utah Conservation Commission, and the Utah Chapter of the American Mining Congress, in co-operation with the U. S. Bureau of Mines, have joined in a plan to locate, classify, record, and develop the mineral resources of the State by collecting all possible information, making free determinations of certain mineral specimens, giving elementary instruction in prospecting and mining, and maintaining a register of prospectors and mining men to bring them in touch with prospective investors. The plan, which is the result of several months' careful study and preparation, is outlined in a joint bulletin issued by the organizations interested. The following information in regard to the deposit from which the samples are taken is desired and should be given in the letters, if possible. Answers to the following will be held as strictly confidential: (1) situation: direction and distance from the nearest post-office, also the nearest railroad. (2) Size of deposit: estimates as to the amount of the material available. (3) Character of the country in which the deposit is situated, that is, whether mountainous, hilly, etc. Is water available? Also timber? (4) Are the specimens especially selected or do they represent the average of the deposit?

ALTA. Last week this district shipped 720 tons of ore to smelters. The principal producers were the South Hecla and Michigan-Utah, also the Emma Consolidated.

TINTIC. According to J. C. Dick, manager of the Lower Mammoth, most of the work is being done at a depth of 1000 and 1500 ft., where results have been fair in opening copper, silver-lead, and zinc ores.

CANADA

BRITISH COLUMBIA

AINSWORTH. The new 300-ton mill of the Florence Silver Mining Co., two miles away, is almost ready for ore treatment. In preparing its mine for production the company has spent \$350,000. Above the second level there is 200,000 tons of ore ready for extraction. The plant consists of sorting-belts, jaw-crushers, rolls, Snyder sampler, Dorr thickener, tube-mill, trommels, jigs, and Deister tables. A concentrate containing 65% lead and 30 oz. silver is to be made, also zinc concentrate as a by-product. The mill building has been well constructed. It is connected with the mine by aerial tram. The hydro-electric plant generates 350 horse-power.

The Standard Silver-Lead mine is to be prospected by diamond-drilling. The ore in this mine occurs as short lenses, there being a number of them, instead of large shoots as in the Coeur d'Alene of Idaho.

ONTARIO

During 1916 the Dome mine produced 1,405,900 tons of ore yielding \$1,960,888. Dividends absorbed \$1,200,000. Costs ranged from \$2.40 to \$2.88 per ton.

YUKON

Mayo. This district is reported to be busy. A number of prospectors are working on silver claims. The Mayo Dredging Co. is constructing a dredge on Hight creek.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

PERCY WILLIAMS is at Prescott, Arizona,

S. J. SPEAK has gone from London to Siberia.

EDGAR A. COLLINS is on a visit to Globe, Arizona.

G. A. JOSLIN is now with O. J. SALISBURY at Salt Lake City.

FRANK D. ADAMS is president of the Geological Society of America.

R. E. VANRUFF is in southern Texas making an examination of oil-land.

J. R. FINLAY is visiting Globe and Jerome, Arizona, and is expected here in March.

GEORGE E. KUBALE, recently at the Panuco mines, in Sinaloa, has left Mexico and is in San Francisco.

E. W. MILLS and JOHN F. MANNING sailed by the *Tenyo Maru* for Japan, going thence to Shanghai, on January 26.

JOHN T. REID will be at New York for two or three weeks after February 15 before returning to Lovelock, Nevada.

J. H. LEWIS, formerly with the Nevada Consolidated Copper Co., is now on the staff of the Braden mine, in Chile.

E. COPPÉE THURSTON is with the smelting department of the Bunker Hill & Sullivan Mining Co., in San Francisco.

EARL C. STEVENS, of Portland, Oregon, has recently been examining placer properties in the southern part of the State.

ALBERT BURCH has resigned as local manager for Bewick, Moreing & Co. and as manager of the Plymouth Consolidated Company.

ALLAN H. ROGERS, of Boston, is accompanying W. J. LORING in a tour of inspection in Tuolumne and Amador counties, California.

W. J. LORING, having established himself in San Francisco, has assumed charge of all the Bewick, Moreing & Co. business in California.

O. H. REINHOLT has been appointed consulting engineer of the Hecla and Octo Mining Co. at Lordsburg, N. M., and also manager of the New Dominion Copper Co. at Globe, Arizona.

JOHN WOODS BECKMAN and HERBERT EMIL LINDEN, with offices in the Balboa building, San Francisco, announce the formation of the Beckman & Linden Engineering Corporation.

C. W. PURINGTON writes to say that the Harvard Club in London is anxious to receive contributions to its War Relief Fund. The secretary of the club is ROBERT GRANT, of Lee, Higginson & Co., at 80 Lombard St., E. C.

WILLIAM A. CATTELL, HENRY S. HOWARD, and RAYMOND ASHTON, announce their association under the firm-name of Cattell, Howard & Ashton, and are prepared to undertake general engineering work, with offices at 68 Post St., San Francisco.

R. K. STOCKWELL, who has been chief engineer and superintendent of construction for the Braden Copper Co., Chile, for the past five years, will soon open an engineering and sales office at Salt Lake City as representative for the Robins Conveying Belt Company.

ALEXANDER M. HAY, prominent in Canadian mining circles, died from pneumonia at Haileybury, Ontario, on January 20, in his 57th year. He was born in Scotland and came to America as a young man. After operating in the United States, Mexico, and Canada, in 1905 he became interested in the Cobalt district, later at Porcupine.

The A. I. M. E. meeting at New York, commencing on February 19, will extend over four days. The first session will include papers on geology, metallography, petroleum and gas, and milling and smelting; second, on iron blast-furnace practice and flotation; and third, on the manufacture of iron and steel. Interesting trips to works will be made.

THE METAL MARKET

METAL PRICES

San Francisco, January 30.

Antimony, cents per pound.....	12
Electrolytic copper, cents per pound.....	35
Pig lead, cents per pound.....	8.25—9.25
Platinum, soft and hard metal, per ounce.....	\$85—91
Quicksilver, per flask of 75 lb.....	\$85
Spelter, cents per pound.....	13
Tin, cents per pound.....	45
Zinc-dust, cents per pound.....	18

ORE PRICES

San Francisco, January 30.

Antimony, 50% metal, per unit.....	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	15.00
Magnesite, crude, per ton.....	8.00—10.00
Manganese, 50% (under 35% metal not desired).....	16.00
Tungsten, 60% WO ₃ per unit.....	17.50—18.00
Molybdenite: The market ranges from \$1.70 to \$1.90 per lb. MoS ₂ contained.	

Tungsten ores had not fluctuated greatly within the past ten years until after the beginning of the War. Since then the range of prices has been great, running from an average price of \$7.30 per unit in 1914 to \$85 in February 1916. Following are the average prices for the past eleven years:

Year	Price per unit WO ₃	Year	Price per unit WO ₃
1906.....	\$6.30	1912.....	\$6.30

EASTERN METAL MARKET

(By wire from New York.)

January 30.—Copper is strong at nominal prices. Lead is scarce; trust (A. S. & R.) prices are higher. Spelter is advancing with sellers reluctant to do business.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

January 23 there was shipped from San Francisco to China about 484,000 oz. of silver valued at approximately \$363,000. Later on in the week about the same quantity also went to China.

The Tonopah Mining company paid \$150,000 on January 20. This company has bullion stored to the amount of 862,922 oz., worth at 50c. per oz., \$431,011.

Spot Straits tin was quoted on January 16 at 44.25c. at New York. An advance from 42.50c. was made during the week. Banca was sold on January 10 at 40.25c., for early shipment from the East, and on January 12 at 42c. The best day of the week was January 12, when 150 to 200 tons changed hands. On January 15 inquiry from nearby positions was large, and probably 400 to 500 tons would have changed hands had the metal been available for delivery in from four to six weeks. Dealers as well as consumers wanted to buy. Tin is the only metal whose market would be improved by an ending of the War, as peace would bring a wider market. The arrivals this month total 2225 tons, and there is afloat, 3708 tons.

PLATINUM

Price of platinum, New York, is \$100 per ounce for soft metal and \$106 for hard. Platinum has advanced within the week \$10 per ounce for both grades of the metal.

Eastern Metal Market

New York, January 24.

Copper prices are again on the upward trend, and already have reached levels that existed prior to the recent peace agitation. Nearby metal has almost entirely disappeared, and all sellers are looking for another boom. The belief is steadily growing that Great Britain must soon close for an enormous quantity of copper for last-half delivery; in fact, it is said that negotiations are under way.

Zinc is easily obtained, but producers are confident that export buying is not far off. Meanwhile prices continue firm.

The lead situation resembles that in copper. Spot and nearby lead is almost unobtainable at any price, but the scarcity is in large part due to the railroad situation. Large consignments are tied up in transit. Meanwhile the holders of lead are commanding fancy premiums.

Tin has advanced because of uncertainty as to what is being done abroad. The cables are irregular and incomplete.

Antimony is higher, one reason for which is the reported curtailment of production in China.

The steel mills are confronted with a flood of export inquiry, while specifications on domestic account are extremely heavy also. It is noted that while the official quotations of the Steel Corporation are 3c., Pittsburg, for bars, 3.25c. for shapes, and 3.75c. for plates, prompt deliveries of those products would be hard to find at those levels. Business in tank plates is freely done at 5c., Pittsburg; in ship plates at 6c.; in shapes at 3.50c., and 3.25 to 3.50c. for bars.

Eastern Pennsylvania mills assert that they are in receipt of less 'wild-cat' export inquiries, and are pleased therewith. The export demand for steel-making iron, especially Bessemer, continues heavy. One inquiry calls for 100,000 tons, for which \$35 per ton is offered. Standard low phosphorus iron has sold at \$57 for both domestic and export delivery. The foundry-iron market is quiet, but strong, the eastern Pennsylvania producers asking \$30 to \$32, furnace, for No. 2. Italy is taking large quantities of materials, her Government having preempted most of the ships that run to her ports for the purpose. She has paid \$62.50 per ton for soft-steel billets, and is buying old steel-axes and other scrap to relieve her needs. China wants 400,000 boxes of tin-plate. On all sides, production is restricted by transportation difficulties.

COPPER

Electrolytic copper for first-quarter delivery is practically unobtainable, and prices are much stronger, some interests refusing to quote altogether. It follows that quotations which are given are nominal. The reason for the strength so suddenly displayed is a general belief that the Entente Allies are seeking to place a gigantic order for last-half metal. For some weeks it has been rumored that such an order was to be placed, but the source of the information was close to Wall Street, and it was not accepted by the trade. More recently, however, it became known that negotiations had been initiated, and something may come of them. How difficult it has been to obtain nearby copper in the past few days is exemplified by the case of a manufacturer who tried to get a price and delivery from 13 different sellers, including both producers and second-hands. Not one would give him a figure, all declaring that they were out of the market for the first quarter. Some May and June metal is obtainable in small lots at 29 to 29.50c., while for the third quarter 27.50 to 28c. is asked. Spot is 32 to 33c., and February around 31c. It will therefore be seen that copper prices are not far from the levels from which they dropped following the recent peace talk. Lake is nominally at the same levels as electrolytic. Brass and copper products continue to hold up well, both as

to prices and demand. Mixed specifications for brass rods bring forth quotations of about 40c., although a desirable order for heavy rods might be placed at 34 to 35c. In tubes, the situation is worse than ever. With the larger sizes having heavy walls, March shipments are considered good, while with the lighter sizes delivery cannot be had until May. Wide sheet brass is difficult to obtain, but April delivery of 12-in. strips can be had at about 42c., commercial specifications, although it is probable that 37c. would be accepted on a big order. Sheet copper is unchanged at the 42c. base, copper rods being held at the same figure. Exports of copper ingots this month total 13,829 tons. The London quotation for electrolytic, cabled yesterday, was £141. For several days the cables have been irregular, some not arriving at all, others being undated. The Perth Amboy refinery of the A. S. & R. Co. has just settled a strike which has greatly hampered production the past week or ten days.

ZINC

A quiet, waiting, but nevertheless firm, market is all there is to record, but producers' representatives are confident that a turn toward higher prices will come soon. They believe that Great Britain will soon buy, apparently basing their hopes on that nation's consumption of copper. Meanwhile prices have held up well, and yesterday a little added strength was shown. January prime Western was quoted around 9.87½ to 10c., St. Louis, for prompt delivery, with New York at 10 to 10.25c. February was 9.75c., St. Louis, and March 9.50c. Brass-mill special was sold this week for early delivery in central New York at 11c. It commands a premium of 1 to 1½c. over prime Western. The London quotation yesterday was £47. Exports of January 1 to 24 totaled 4367 tons. Sheet zinc is unchanged at 21c., carload lots, f.o.b. mill, 8% off for cash.

LEAD

The situation in lead has closely resembled that in copper. Spot supplies are extremely low, and premiums are easily obtainable. Most of the trouble with lead is traceable to transportation delays, which have held back needed supplies from manufacturers, making it necessary for them to seek relief in the market despite the fact that they might have plenty of lead under contract. For prompt delivery, independent sellers have been readily getting 7.75c., New York, and 7.62½c., St. Louis, and higher. The A. S. & R. Co. continues to quote 7.50c., New York, although it is well understood that it is not selling at this figure, but using it as a basis for computing an average price. It has been reported from day to day that the big producer intends to advance its quotation. Meanwhile the metal is so scarce that a great deal of business has been turned down. The London quotation for spot, as cabled yesterday, is unchanged at £30 10s. Exports from the 1st to 24th were only 937 tons.

TIN

The quotation for spot Straits yesterday, the 23rd, was 45.50c., New York, with not much offered. Supplies seem to be scarce, but a more potent reason for the higher price is the uncertainty under which both sellers and consumers are working because of the irregular cables from London. For the better part of a week no worth-while cable was received until yesterday. On some days no news came at all, while on others the cables were not dated and consequently of little value. The arrivals this month total 2650 tons and there is afloat 3558 tons. Banca tin is scarce, also, but more generous arrivals are expected.

ALUMINUM

The quotation for No. 1 virgin aluminum, 98 to 99% pure, is easier at 56 to 60 cents.

Twelve Years' Metal Prices

The above chart, prepared by the *Steel and Metal Digest* of New York, was plotted according to the monthly average prices of electrolytic copper, Straits tin, aluminum (98-99%), antimony (Cookson's; prior to August, 1914, Chinese and Japanese thereafter) all New York, and pig lead and prime Western spelter, St. Louis.

Industrial Notes

Information supplied by the manufacturers.

Short-Centre Belt-Drives

One source of power loss is in the slipping of belts, even the best belt-drive involves 2% slip, and some drives 5% or more, which is serious. To overcome this loss it has been customary to use long belts or greater tension to get more traction. Belt-tighteners are forced with great pressure against the belts, and while slippage can be overcome to a certain extent by such means, it more frequently results in excessive bearing pressure, over-heating, etc., and simply consumes the power by friction at the bearings instead of by belt slippage. With the object of keeping down bearing pressure, this condition of

DIAGRAM EXPLAINING PRINCIPLE OF SHORT-CENTRE BELT-DRIVE.

affairs is responsible for the considerable use of silent chain-drives, so as to get sufficient drives at short centres with freedom from slip. But such drives have about reached their limit on account of high first cost, expense of upkeep, and the constant attention they require, together with the fact that the speed of silent chains is limited to about a quarter of what has been found entirely practicable with good belts and pulleys.

horse-power with practically no slip. This system was studied by the engineers of the Meese & Gottfried Company of San Francisco, and other Pacific Coast factories, and developed to a high state of mechanical perfection; in fact, this firm is the only one that has gone thoroughly into the engineering of the subject in this part of the country, and though a new undertaking, has already supplied these drives to operate 10,000 hp. The principle can be gathered from the accompanying diagram, and is totally different from a belt-tightener in several important features, as

- (1) It does not cause an increase in belt-tension for a given horse-power.
- (2) It operates just as satisfactorily on short centres, where formerly a belt-drive would have been impossible.
- (3) It does not increase the bearing pressure with consequent over-heating and rapid wear of same.
- (4) It makes possible the transmission of almost twice the horse-power heretofore considered practicable with a leather belt.
- (5) It is easy on the belt and with a good flexible grade of belting it causes no injury.

On first seeing one of these drives the average mechanic would class it as a swinging-belt tightener drive, but would be in error, as can be seen from its distinctive features enumerated above, for it is not merely a 'device' but is more properly a system, the successful installation of which depends on the proper position of the idler, its effective weight relative to the horse-power and speed of the drive, together with the pre-determined slack in the belt, as the belts are purposely made loose. The angle and direction at which the drive runs must also be considered, as the idler may be controlled by weights on levers arranged at the proper angle, or may be pulled upward or sidewise by ropes and counter-weights. On heavily pulsating loads, pneumatic-shock absorbers are sometimes connected to the oscillating frame to steady it. This new development in short-centre belt driving undoubtedly has a great

PHOTOGRAPHS OF SHORT-CENTRE BELT-DRIVE INSTALLATION IN OPERATION.

These pictures show a motor running at 700 r.p.m., driving by a 20-in. wide rubber belt a double-acting duplex air-compressor at 140 r.p.m., consuming 150 hp. Note the close centres of pulleys.

On account of the constant tendency toward higher speeds in prime-movers and machines, it was with great interest that the experiments with short-centre belt-drives controlled by yielding idlers, carried on in Europe during the last few years, were watched by the mechanical engineers of this country. The new system involved the use of especially constructed pivoted idlers, mounted on ball or roller bearings, operating against slack belts somewhat in the nature of a belt-tightener, though in principle quite different, as will be explained, and permitted of short centres, at the same time giving greatly increased

future, as it accomplishes what can be done by no other means—transmitting from the smallest to the heaviest horse-power smoothly and silently at high efficiency, and at speeds which would be quite impossible with silent chains. Practically all belt-drives from the heaviest main drives down come easily within its scope.

The annual convention of the sales and factory organizations of the CHICAGO PNEUMATIC TOOL Co., was held on the 11th, 12th, and 13th of January. About 100 were present.

EDITORIAL

T. A. RICKARD, Editor

WHY not make froth in a cyanide solution and kill two birds with one stone?

IMMIGRATION improved in 1916, the total of incoming passengers at New York, for example, being 259,367 as compared with 216,274 in 1915. But in 1913 the arrivals numbered 1,332,200. These statistics are important in their relation to the supply of labor.

GOLD output of the Transvaal in 1916 is stated at \$197,424,670, or \$12,873,365 more than in 1915. The yield of the Indian mines, in the Kolar goldfield, declined to 541,077 ounces, as compared with 556,596 in 1915 and 602,006 ounces in 1914. The West African and Australian productions also exhibit a decrease.

CANADA now can obtain all the lead, copper, and zinc that is needed for industrial purposes from the refinery at Trail, so says the annual report issued by the Consolidated Mining & Smelting Company of Canada. While the copper production of British Columbia is more than enough for Canadian needs, it is not refined in Canada. The domestic refinery at Trail is an establishment of which the Dominion has reason to be proud.

WE never thought so much of the Rocky Mountain Club as when it set aside the \$500,000 pledged for a new house and gave this money to the Belgian Relief Fund. Mr. W. B. Thompson set a fine example by subscribing \$100,000. There should be many more in the club willing, as there are many more able, to do likewise—for example, Mr. Bernard Baruch, who testified at the 'leak' inquiry that he made \$476,178 during the peace scare.

IN the midst of bigger events the Mexican episode is overlooked. Another vera-crusade is ended and General Pershing's expeditionary force has been withdrawn. Villa, whom the expedition was meant to kill or capture, is still on the rampage, stronger than before. However, the withdrawal of the American troops will serve to strengthen Carranza rather than Villa, robbing the latter of the claim that he is the object of foreign incursion. The pacification of Mexico will have to wait on the conclusion of the larger affair in Europe.

WHAT is happening in Mexico is suggested by the events at Panuco, in Sinaloa, where the Carranzista people seized an important mine and removed the pillars of ore left to support the workings; they did no devel-

opment work but simply 'guttled' the mine. Operations were directed, for the pseudo-government, by Villalobos, a vaudeville singer. The Spanish-Mexican company owning the property has claimed \$2,000,000 as indemnity. The product of the mine is a simple silver ore becoming coppery in depth. By cyanidation the best extraction is only 55%, whereas flotation gives a high recovery. The high cost of cyanide will give the new process an opportunity to establish itself.

WE publish an article on mining of the precious metals in the Chinese province of Chihli, by Messrs. A. S. Wheler and S. Y. Li. Mr. Wheler has recently resigned from the post of Inspector General of Mines to the Chinese government. He is one of several capable men that have tried to help the Chinese in framing workable regulations for their mining industry, but without success. Messrs. Wallace Broad and G. G. S. Lindsey are among the others that engaged themselves in this Sisyphean task.

ORE does not persist indefinitely in depth, but rarely it will continue downward farther than expert opinion anticipates. Thus 5% copper ore, 50 feet wide, has been cut at 2800 feet deep in the Leonard mine at Butte. At one time the hypothesis of secondary enrichment by chalcocite precipitated from descending solutions caused engineers to expect non-persistence in depth—and by 'depth' at Butte was meant 2000 feet or even less. The primary origin of the Butte chalcocite from ascending solutions is now at least as well substantiated as the less cheerful hypothesis.

DURING the two past calendar years the net inward flow of gold into the United States has been \$950,000,000, as against a net outward movement of \$193,000,000 in the two preceding years. In the one month of December the gold imports were \$158,000,000. During the last 24 months this country has lent \$2,400,000,000 abroad and bought back its own securities to even greater value. The trade balance for the 29 months of the War has been nearly equal to the value of the exports during the previous similar period. In 1916 we sold goods at the rate of \$54.81 worth for each inhabitant of the United States.

KENNECOTT COPPER is still being puffed by the *Boston News-Bureau*. We understand that there really was some serious talk about a consolidation of the Kennecott, Chile, and Utah copper companies, but a vigorous protest was made by the mining men that hold

large blocks of Utah Copper. It is recognized by them that there is no valid economic reason for the further consolidation, creating a monstrous enterprise with widely scattered interests. Such a scheme would offer chances for financial legerdemain, that is all. Utah Copper, owing to its interior position, is safe from the effects of naval warfare and owing to its employment of high-priced skilled workers it is not likely to suffer from labor troubles. Well managed, well organized, and based on splendid reserves of ore, the Utah Copper enterprise would gain nothing by falling into the maw of the Guggenheim agglomeration.

MUCH of the preparedness talk is like that of the old woman that stepped off a moving car backward shrieking 'safety first.' The Secretary of the Navy has stated that the manufacturers bidding for the construction of four battle-ships demanded a 35% margin of profit, amounting to \$5,000,000. When an appeal was made to the bidders to reduce their bids on patriotic grounds, only one acquiesced—and that one, the Bethlehem Steel Corporation "for self-advertising purposes, made public its decision to lower the price 10% as a patriotic service to the United States." The company still made 25% profit. It is no wonder that a Government steel manufactory is under discussion.

AMONG the consequences of the War we may mention a depreciation of \$4,610,000,000 in the aggregate market-value of 387 representative securities quoted in London. In 1916 the net loss was \$745,000,000, the biggest drop having taken place in the ten days preceding the declarations of War—July 20 to July 30, 1914—when the loss was \$2,830,000,000. On the other hand the rise in the price of shipping is equally astounding. The steamer *Hercules*, which was sold for \$425,000 in 1915, brought \$1,300,000 in 1916, although in 1904 she changed hands for \$161,250. The *Askelad* sold for \$692,500 in 1916 and for \$72,500 in 1912. The *Demetrios Inglesis*, which sold for \$400,000 in 1916, was worth only \$35,000 five years earlier. Sailing-ships likewise have sold for 10 and 15 times their pre-War valuation. It's an ill wind that blows no one good.

SOME mineralogical names are deceptive; for example, molybdenite is molybdenum sulphide; molybdomenite contains no molybdenum, but is lead selenite. Copperas includes no copper, but is the sulphate of iron. Limonite is brown iron oxide and contains no lime. Argentine is a pearly lamellar variety of calcium carbonate, or calcite; whereas argentite is black silver sulphide. Black-lead is a common name for the amorphous form of carbon technically known as graphite. It contains no lead. Chloride and chlorite are as far apart in composition as are quartz and limestone. Glaucofanite is a blue variety of hornblende, and glauconite is a green scaly iron silicate. Chrysolite, or olivine, also known as peridot, is a silicate of iron and magnesium; and chrysotile is a magnesium silicate, a fine, silky cross-

fibre variety of asbestos. Soapstone feels unctuous and soapy to the touch but it is destitute of soap. Wolframite is iron-manganese tungstate; wulfenite is lead molybdate, yet the two are often confused. Chalcodite is a bronze-colored iron silicate of velvety appearance with a micaceous structure, and chalcocite is copper sulphide. Cyanite is an aluminum silicate and bears no relation to cyanide nor to the rock syenite. Pitchblende is a uranium oxide and contains no pitch, though resembling it in appearance, nor is it related to zinc-blende.

IN these days we hear much concerning an international tribunal that is to be created at the end of this war in order to put an end to war. Perhaps those of us that desire greatly to see Mexico pacified will have to wait for that embodiment of peaceful sentiment in order to put a quietus on the 'istas rampaging south of the Rio Grande. In his latest article Mr. H. G. Wells says: "This International Tribunal, if it was indeed to prevent war, would need also to have power to intervene in the affairs of any country or region in a state of open and manifest disorder, for the protection of foreign travelers and of persons and interests localized in that country, but foreign to it." That seems to cock an eye at Mexico. Well, if no one else will do it, let it be the International Tribunal and if it does it we shall not grudge the capitals.

NEVER were we so proud of our craft as when we heard it said, at the dinner given by the Friends of France to the 21 Stanford students that had volunteered for Red Cross work, that their enthusiasm for this service had been aroused by the editors of college periodicals. Moreover, it was stated that several of those volunteering for this noble work had given up chances of being editors of the University press, and this was deemed a real sacrifice. Evidently the young editors are able to create opinion of a worthy kind and willing to live up to it themselves—which is exactly what our local daily press fails to do. The young men about to go to France in a humane endeavor to lessen suffering and to save life are a credit to the State. Stanford has won imperishable renown for the work done by her sons in Belgium and the Red Cross in France. A university indeed! if a seat of learning cannot evoke the generous sentiment of youth and if it is unable to express its high ideals by personal service, it is a poor sort of university.

DISCUSSION this week includes a number of interesting letters. Mr. John F. McLennan writes concerning the distribution of ore as affected by faults. He offers a reasonable explanation for the localization of rich ore between the surface and a fault-plane that acts as a barrier to the descent of solutions enriched by weathering. Further contributions on this subject will be welcome. Mr. Horace V. Winchell replies to some comments of our own and criticizes them in a manner to which no objection can be taken. We would like our readers to believe that criticism of editorial remarks is

always welcomed by us, because we are fully aware of the fact that such criticism is usually more interesting than the expression of a polite agreement or a flattering concurrence. Another letter on the revision of the mining law comes from Mr. A. E. Robinson, who discusses sundry changes recently proposed. He keeps the prospector in mind, as we think he should, and objects to the proposal to locate square claims along lines following arbitrary courses. He also protests against the substitution of money payment for assessment work, and in this he is likely to voice general sentiment in our mining districts. Mr. A. E. Drucker, who returned recently from Colombia to New York, offers some timely remarks on ball-mills. He refers to a controversy conducted in the pages of *The Mining Magazine*—of which controversy we beg to say that it was not in the least convincing because it was conducted for the most part by gentlemen in the employ of the manufacturers of the machines discussed. To Mr. Lucien Eaton, superintendent of the Cleveland-Cliffs iron mine, we are indebted for his answers to the pertinent questions propounded by A. B. C. in our issue of January 13. The information given by Mr. Eaton will be appreciated by many of our readers and may provoke some of them also to try a hand at the catechism submitted by the anonymous seeker after knowledge. The letter from a lady finds acknowledgment in an editorial foot-note. Speaking of Belgian Relief, we dislike to think of the effect of recent events on the labors of the Commission and hope that Mr. Hoover will be able to proceed with his good work even though the shadow of war be further darkened over its first unhappy victims. Mr. W. A. Freeman, recently arrived from Sydney, gives an interesting bit of information concerning the taxing of mines in Australia. He and his friends, who are operating a tin mine in Bolivia, propose to incorporate a company in California, mainly to protect themselves against excessive taxation in Australia. The registering of another of their companies in the Malay States serves likewise to draw attention to the effects of war taxation on the mining business.

On the Edge

At this time of writing the United States is still at peace, but an act that would compel a declaration of war against Germany may follow at any moment. The rupture of diplomatic relations with the most aggressive of the belligerents in Europe is an event that cannot fail to make an emotional appeal to every thoughtful man and woman in the country, and all the more because it has come after a long period of patience. Good reasons for giving Count von Bernstorff his passports were afforded, in the opinion of many, at a much earlier date and if drastic action has been taken now it is due to the logic of the position into which the negotiations arising from the indiscriminate destructiveness of the German submarines has forced the Government of the United States. The German note of January 31 called inevit-

ably for the response made by the President on February 3. The German pronouncement expressed a policy of sheer desperation and a determination to fight without regard for any of the few remaining rules of the game that survive the welter of savage warfare. It flouts the opinion of the world and at last places the chief neutral in a position where further inaction would be stultifying. The President has justified his policy and disarmed his critics whether among his own people or abroad. After an exhibition of patience and long-suffering that has evoked the jibes of his political opponents and the hardly disguised satire of foreigners, he has risen to the occasion in a manner and with a spirit that must arouse not only the enthusiastic support of every American, but also the cordial admiration of the other neutral nations. The moral effect of his action will be all the greater on account of his forbearance, and the Government of the United States will be enormously strengthened thereby in any later effort to promote the lasting peace of the world. The break with Germany is based on clearly legal grounds. It is the sequel to an unequivocal declaration of the American intention to uphold "the sacred and undisputable rules of international law and the universally recognized dictates of humanity." Unless we had made up our minds to stand aside and see the world sink into a veritable slough of barbaric reprisals, we were bound to take the action that the President has taken for us as a people. He has done it promptly and with all the impressiveness that the occasion demands. It remains for every good citizen to exercise self-control. Those that are of European origin or still retain European ties, of sentiment or blood, will now prove their loyalty to the country of their adoption by showing sympathy for the many citizens of German origin to whom this crisis must be soul-harrowing. From the searching of spirit that must follow the break of friendly relations with Germany, and probably with her allies also—not to mention the possibly graver event—there will come a filtering if not a fusion that will do more to unify the American people than all the Fourth of July orations that were ever made. We believe confidently that the mental detachment, verging on vacuous aloofness, that has marked a large part of our people, especially in the West, during the last two and a half years will now be submerged by eager interest in the history-making events of the hour and that the call to loyalty will fuse the discordant elements in our population, kept apart alike by European antagonisms and by the official dictum of neutrality. Even the most pacific of men must have noted the disintegrating effect of the War on our people so long as it appealed to them variously and at different angles, but now the clear stand taken by the President, with the full support of Congress, in behalf of international law, will make us one—a nation indeed, united in resolute defence of the right to live and let live, of those conventions of conduct upon which civilization rests, of those sanctities of international justice without which man might as well return to the ape and tiger existence of the jungle.

Subsidence at Treadwell

In this issue we publish an abstract from a recent report on the dangerous condition of the Treadwell mines. Our readers will recall that the consolidation of this group of properties on Douglas island, Alaska, was recommended by Messrs. H. C. Perkins, Hennen Jennings, and F. W. Bradley in a report dated July 31, 1916, the more important part of which was published, with editorial comment, in our issue of August 26, 1916. In that report the three distinguished engineers endorsed the resident manager's estimate that only 7,010,000 tons out of the 15,678,600 tons of ore assumed to be blocked-out could be saved owing to the caved condition of the mines. The loss of ore supposed to be in reserve was an important feature of that investigation, although it was not emphasized. However, in the concluding paragraphs of the report a proper stress was laid on the seriousness of the caving, which was used as an argument for advocating common control and concerted action by this group of mining companies. Moreover, in the appendix, Mr. H. G. Wayland, the general superintendent, stated frankly that if the caving extended to certain vital points, notably the Central shaft, it would entail such a loss of ore as to reduce the estimated profit in the developed ground of the Treadwell and 700-Foot mines to "a nominal figure." The development of dangerous lines of weakness in the Mexican mine was also described. In the later report by Mr. F. W. Bradley, the president of the consolidated companies, it is made clear how serious is the condition of the workings. The caving of the stopes and other evidence of subsidence are described, together with the measures taken to restrict the damage, especially in its effect upon the recovery of ore. We conclude, not without regret, that the paragraph appearing in our issue of July 3, 1915, was true in substance and in fact, although official objection was made to that paragraph and we were assured—as we were not sorry to note in our issue of July 17, 1915—that "the loss of ore would not be serious and the workings were not endangered." Evidently they were, for in June 1915 a large cave developed between the 750-foot and the 900-foot levels of the Alaska Treadwell mine and big cracks appeared on the 440 and 600-foot levels of the Mexican mine, reaching the surface and endangering the Central shaft. Within a year thereafter the settling of the ground had damaged several buildings, including one of the stamp-mills. The crack near the Central hoist-building, first noticed in June 1915, has widened to four or five inches and is now supposed to extend to the 440-foot level at least. That the ground was settling, in consequence of the extensive excavations made in the lode, was known 11 or 12 years ago, as far back as the management of Mr. Joseph MacDonald. Cracks were noted near the big open-cut even at that time. As the huge pit or 'glory-hole' was enlarged, year after year, the support of the foot-wall was removed and the rock was pushed out, breaking in masses that slid to the bottom. One of such masses contained 600,000

cubic-feet, or 45,000 tons. As the open-cut was enlarged and deepened, partly by caving and subsidence, the broken ore was withdrawn at successive lower levels, and when the ground began to settle bodily the ore and rock were extracted through bulldozing-chambers, reducing the cost to a minimum and creating a fictitious notion of economy. It is doubtful if the ore produced below the 1700-foot level during recent years would have yielded any profit if it had not been for the self-broken ground above. When withdrawing ore in this way the management could not know from what part of the mine the product came, for in places the broken lode-matter ran freely and in others it was soon blocked. Evidently a long pipe of running ground was formed in one place, for roots and other surficial debris came down to the 1400-foot level. There has been a steady decline in grade below the 1700-foot level. As no more ore can be drawn from above this level until it is decided finally to abandon the workings, the available reserve has shrunk to a relatively small tonnage, considerably below that given in the consolidation report, for below 1700 feet there is not much ore assaying above the \$2 per ton required to leave a margin of profit; it being probable that \$2 will be the future cost, including loss in tailing. The point we make is that the figures of cost appearing in recent annual reports are illusory for the reason that insufficient allowance has been made for the large proportion of ore on which no mining or development work had to be done, thanks to the caving that in the end has proved so disastrous to the welfare of the mines.

This brings us to the danger of the mines being drowned by the admission of the water of Gastineau Channel, which is the strait that separates Douglas island from the mainland and under which the workings extend. Until 1916 the inflow of salt water was not serious, but during last year the volume of it is estimated at 39 gallons per minute. This is nothing in itself, but it may be ominous. The management believes that if proper precautions are taken "no disastrous flood of salt water will follow," and this, we may add, is the opinion of experienced men on the outside. The slimed tailing discharged from the four mills was expected to seal any cracks completely and thus serve as a protection from inundation. It is believed that this expectation is well founded, and attention is drawn to the fact that the lower levels are bone-dry. Several preventive measures have been suggested and every effort is being made to safeguard the mines. The report made by Mr. Bradley states the essential facts frankly and clearly. It is easy to be wise after the event, but for that kind of wisdom we have no liking, so that we do not feel called upon to offer any top-lofty criticism. All mines become subject to subsidence when an inclined lode is excavated over large areas to a great depth. That is the experience to-day in the copper mines of Michigan, on the Rand, and on the Kolar goldfield. The aim of engineering is to delay the subsidence and to save as much ore as possible up to the time when the mine has to be surrendered to the chief miner—nature.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Effects of Faults on Richness of Ore

The Editor:

Sir—Relative to the enquiry appearing on page 902 of your issue of December 23, it is evident, although not explicitly stated, that the writer desires an explanation of the principles governing great variations in richness between specified portions of faulted orebodies.

In illustration of the point in issue, the accompanying

sketch shows a section of a vein that has been sheared, and then in part heaved from its original line to a new position, constituting a dip-fault. Of the two portions of this vein, that overlying the fault-plane has been enriched by ore-bearing material extracted from various sources within the inclosing rock, through decomposition due to weathering. Furthermore, and probably in preponderating measure, the upper portion has been enriched through progressive downward concentration within the orebody by re-precipitation from solution, much of the enriching material having been gathered from upper horizons that exist no longer.

In the process of downward enrichment, though the immediately higher portion of orebodies may be found favorably productive, it is quite frequently observed that special enrichment, from valuable material that has passed below the zone of weathering, occurs in the upper part of the zone of cementation, or zone of greater coherence. Such enrichment usually rests above an impermeable barrier—a fault-plane, for example.

That portion of the vein, underlying the fault-plane, may be considered as beyond the reach of important alteration, and so securely sealed overhead as to render appreciable subsequent enrichment improbable—the ore still retaining its main primary characteristics.

In orebodies displaced by strike-faults, analogous con-

ditions, as far as the result of subsequent energy is concerned, are likely to obtain, owing to the probability of their separated parts lying in a common horizon.

San Francisco, January 2.

Mining Law Revision

The Editor:

Sir—I have read with appreciation the editorial comment in your issue of January 13 upon this subject. It would appear that you are under the impression that objections to the mining laws are of recent date. Your remark to the effect that “thirty years ago their propaganda would have been timely” is but another illustration of the fact that those who criticise and oppose revision are not fully informed in the matter. More than thirty years ago a prominent mining engineer made the following statement:

“Enough has I think been adduced to prove that the present law is vicious and inexpedient, that its provisions bear hardly upon the mining industry, and it ought to be either repealed or essentially amended.”

He continued his discussion of the conditions as they existed in his day by using the same terms: “Uncertainty of title,” “fear of litigation,” and “blackmail,” which are today used in discussing this matter. (Document No. 233, 64th Congress, page 37.)

It further appears from your remarks that you consider “a detached view of this contentious subject” “the one qualification that those less minutely informed may possess.” With this opinion thus frankly expressed I am quite in accord. Our critics and opponents seem to be equipped with this one qualification, and I leave it to your readers to decide whether intimate familiarity with a subject is not better qualification than “a detached view.”

Answering now the inquiry contained in your last lines, I beg to call your attention to the fact that for the past four years those who have been recommending revision of the mining laws have expressed themselves as clearly in favor of the abolition of the ‘discovery’ requirement. Thus in the report of the Committee on Mining Law of the Mining and Metallurgical Society, dated March 15, 1913, the second recommendation reads as follows: “Mining claims should be locatable regardless of a ‘discovery’ and held only so long as the specified development work is performed,” and in a communication to the American Institute of Mining Engineers in February 1914, a copy of which I enclose for your in-

formation, the question is considered at length, and the following statement appears: "The requirement of a discovery before location is antecedent to the granting of any exclusive possessory title, and is therefore not only irksome and deterrent of results in practice, but worn in principle." (H. V. Winchell, Trans. A. I. M. E., Vol. XLVIII, page 368.)

Now, Mr. Editor, I congratulate you upon the discovery of one feature of the mining law which needs revision. I feel encouraged and entertain hope that a few more steps of progression from the "detached view" will lead to the discovery of still other features in which improvement is possible and desirable.

Minneapolis, January 23. HORACE V. WINCHELL.

The Mining Law

The Editor:

Sir—I would call attention to several suggested changes in the Federal Mining Code, which, being apparently subordinate, have been but little discussed, but which would, of enacted into law, have an effect greater, and more detrimental to the mining industry, than might be supposed. I refer to the proposals (a) that the new square claims shall have north-south and east-west sides, (b) that an equivalent sum of money may be paid into the U. S. Land-Office in lieu of the performance of assessment work, and (c) that a patent shall be applied for within seven years after location. I am not aware that there is any general demand for these particular regulations—in fact nearly all Idaho mining men are opposed to them, nor does it appear that any general good would result from them. We must not overlook the effect upon the prospector of any change in the present law. It is admitted that we ought to stimulate prospecting as much as we can, and if the discovery and development of mineral land is waning (except for the temporary stimulation given by War prices) under the present simple procedure for locating and holding a claim, we cannot expect any relief if we require more from the prospector than now is demanded. He is accustomed to staking his claim in a very simple manner, which is as it should be, for he prefers to spend his time in developing his find, rather than in setting his monuments at the corners of perfect rectangles. It would certainly work a hardship on him if he were compelled to have the boundaries of his claim on arbitrary courses, and particularly so if it were on unsurveyed land.

The prospector would receive no benefit from a regulation that would permit his neighbor to pay the Land-Office \$100, or any other reasonable amount, in lieu of doing his annual work. Admitting that many prospectors try to hold more claims than they can 'represent' properly, I think the majority try faithfully to perform their annual work, and they would regard such a regulation as class legislation favorable only to the non-resident owner who is not diligent in improving his property.

In the West many claims are owned by men who are

financially able to perform only the necessary annual labor. The development of these claims progresses at the rate of \$100 per year, and very few of them can make such a showing in seven years that capital may be secured to complete their development, and only an occasional one makes a mine in that time. As it costs about \$300 to patent a 20-acre claim, such a law would mean at best that the development of each seven-year-old claim owned by poor men would be arrested for three years, and in many cases would compel a complete abandonment. Is that not depriving a man—an indispensable man in the mining business—of his property without compensation? Multiply the development done in three years by the number of seven-year-old claims in the entire mining territory of the West and the product will be the annual cost to mining development.

Any change in the law that applies particularly to prospectors, except perhaps a regulation that will cause, in those cases where there is delinquency, a full compliance as to annual labor, will work a hardship on prospectors, and will defeat one important object sought to be attained by a new code, namely, the stimulation of prospecting and development.

A. E. ROBINSON,

Boise, Idaho, January 19.

Ball-Mills

The Editor:

Sir—Wet-crushing ball-mills are occupying the keen attention of every progressive and up-to-date metallurgist at the present time. Interesting articles and discussions have appeared in your paper on this subject during the past year.

I recall the discussions appearing in the *Mining Magazine* during May to August 1914 between Messrs. Hardinge, Farrant, Catlin, and myself regarding short tube-mills *v.* conical mills. At that time short tubes (wet crushing cylindrical ball-mills) were not in use to any extent in the United States. Their development here has taken place during the past two years. They are rapidly taking the place of stamps, rolls, and Chilean mills.

The efficiency of the ball-mill will be increased materially in the future by a more complete elimination of the undersize material from the feed. At the present time this undersize product, included in the direct and return feeds, amounts to as high as 20 to 30% in some mills. Screen-classification would more completely accomplish this than either hydraulic or mechanical-screw or rake classification. There is plenty of room for improvement along this line.

I believe that a Krupp ball-mill that is largely used throughout Western Australia is worthy of some consideration. There it is used mainly for the dry crushing of telluride gold ores, which require complete roasting before cyaniding. This ball-mill when used for wet crushing should have a large capacity owing mainly to the large peripheral-screen discharge. As soon as the ore becomes fine enough, it is immediately discharged from

the mill, and there is practically no unnecessary grinding. Any machine that discharges its product quickly, when it becomes of the required size, will be the most efficient.

Has the Krupp mill ever been used for wet crushing in this country? If not, what are the arguments against it? Let us have some discussion on the Krupp type of mill *v.* the Marey.

A. E. DRUCKER.

New York City, January 3.

[The chief argument against the Krupp mill is that Essen is blockaded.—EDITOR.]

Some Pertinent Questions

The Editor:

Sir—The questions asked by A. B. C. in your issue of January 13 are good subjects for discussion, but they are stated too indefinitely to receive definite answers. There are too many conditions affecting work underground, such as hardness of ground, size of opening, condition of equipment, and so forth, to permit of explicit answers to most of the questions. Nevertheless, to help the discussion along, I beg to submit the following answers, strictly off-hand:

Question: How many feet of drilling should be done by a miner on an 8-hour shift, working with a single-hand hammer?

Answer: Anywhere from six inches to 50 ft. There is ground in the Cliffs Shaft mine where a man couldn't drill six inches a shift with a single-hand hammer, and I have seen a man put in three five-foot holes in the ore in the Ashland mine with a jumper in ten minutes. These represent the extremes.

Question: Same as above, but with a drill of the jack-hammer type?

Answer: Drilling-speeds by test, run from less than one inch per minute to more than two feet per minute. And the amount of drilling a man should do in a shift varies in somewhat the same ratio. A man can't stand the vibration from one of these machines during the whole shift, and should have a chance to change off part of the time at some other occupation.

Question: Same as above, but with 3½-inch piston-drill, using 90 lb. air-pressure?

Answer: Few men are interested in 3½-inch piston-drills nowadays, except in quarries. When the ground is too hard for a jack-hammer, it is time to rig up a No. 18 Ingersoll-Leyner, or a Sullivan DR6, or a Denver Dreadnaught.

Question: How long a time should a shoveler take to fill a car of 1800 lb. capacity with ordinary quartz ore, or rock, shoveling from the rock-floor of a drift?

Answer: About 20 minutes. The character of the ore, size of pile, size of drift, and height of car are all functions of the variable, to say nothing of the method of payment. Some men do well to load 10 tons per shift, and others will load and tram 18 tons every day. I would be almost ashamed to say how many cars I

have seen three men load in a shift in the Roosevelt tunnel.

Question: What is the average cost of shoveling a ton of rock into a car from a rough floor underground when no shoveling-plank or metal sheet is used?

Answer: About 15 cents. Here again the conditions of work as well as the wage-rate and system of payment are controlling factors.

Question: What is the increase of efficiency if a shoveling-floor of plank or a metal sheet is used?

Answer: About 20%. In soft hematite there is little, if any, increase in efficiency, most of the 'mucking' being from the top of the pile. In extremely rough ground the increase may be as high as 50%.

Question: How far is it safe to carry the face of a drift beyond the last set of timbers?

Answer: Somewhere between six inches and 6000 ft. There are places in the Salisbury mine where it is unsafe to open up at all beyond the last set of timbers without fore-poling. A little over a mile away at the Cliffs Shaft mine there is a drift on the 10th level that is nearly 6000 ft. long without a stick of timber in it.

Question: How far should a trammer push a loaded car on a fair track underground in one minute?

Answer: About 250 ft. The size of the car, grade, and gauge of track, size of rail, length of wheel-base, and type of bearings all have considerable influence on speed of tramping. As a general thing a short wheel-base, narrow gauge, light track, and roller-bearings give the best results. These results are usually obtained where the car is light and the grade is such that the men can ride out with the load. This can be easily accomplished by using roller-bearings.

Question: What is the best angle of inclination for a raise that is to be used for the passage of ore or rock?

Answer: About 65°. With hard ore running down long raises that are not timbered it is well to have a bend in the raise about 25 ft. above the chute, the bottom 25 ft. being at an angle of 50°. This takes the weight off the stoppers or fingers.

Question: How many cubic feet of quartz in place are required to weigh one ton?

Answer: 13.

Question: How many feet, if broken?

Answer: About 20 in a skip or car—16 or 17 in a good-sized dump.

Question: How many cubic feet of fresh air per minute should be sent to the face of a drift where two men are at work, where the place is lighted by candles—one for each man?

Answer: 200 cu. ft. The amount of air per minute per man underground required by various statutes varies from 50 to 300. With much decaying timber 200 cu. ft. per man per minute has proved satisfactory. Without rotten timber 100 cu. ft. per man per minute should be ample, especially if carbide lamps are used instead of candles.

Question: What number of hours of actual work per shift results in the greatest efficiency of men?

Answer: Seven.

Question: How far apart should loading-chutes be placed on a level to get the greatest economy in handling ore in the stope above?

Answer: 25 to 30 ft. Here again the width of the vein and the amount of the ore to be passed through the chute have an important bearing on the decision. If chutes are not more than 30 ft. apart on centres no tramming is necessary in the stopes.

Question: Is the bonus system advisable in underground work? If so, why?

Answer: Yes. By paying a man a minimum wage with a bonus for every ton of ore or foot of raise or drift, or for every ton of ore or foot of raise or drift over a certain amount, a more uniform rate of payment per unit can be set than with a straight contract system, where supplies are charged to the contract. The labor charges for different kinds of ground are much more uniform than the supply charges. The bonus system also prevents disputes as to the rate to be charged for supplies furnished.

Question: Is the contract system in mining-work a good one? If so, why?

Answer: Yes; but in many ways the bonus system is better. With uniform conditions of work the contract system works out very well. In tramming, a system based on the cost of filling the car and the distance trammed is advisable. I worked out a system of this kind at the Cliffs Shaft mine a few years ago, and at the same time a similar system was started by the Moctezuma Copper Co. with good results. Wages are radically different at the two mines, but the cost per ton was nearly equal.

LUCIEN EATON.

Ishpeming, Mich., January 17.

The Great Calamity

The Editor:

Sir—May the very small voice of femininity speak in the great engineering world? First, I want you to know that you have among your faithful followers an embryo mining and metallurgical engineer of the feminine persuasion; some day I may want to "speak out loud" and I don't want to take you by surprise.

Inspired by your worthy editorial on 'The Great Calamity' and its reformatory result, as confessed to by the gentleman who refrained from "making an ass of himself," comes this idea: who of us would have the courage to dispense with tobacco at one of our banquets and use the money saved for charitable purposes? Or why not put aside for the Belgian Kiddies the price of a box of cigarettes every time "we" indulge in such a luxury?

M. L'A. C.

Stanford University, January 22.

[Certainly, the lady ought to put aside her cigarettes "for the duration of the War" and give the saving to the Belgian Relief Commission. We know several men that have abstained from the use of cigars—substituting

the pipe in order to save money for this worthy purpose. We are glad to count this fair correspondent among our subscribers and are aware that we number among our readers many of the wives of mining engineers and metallurgists. It is an honor and also a stimulus to good work, for there is no better critic than a refined woman. —EDITOR.]

Taxation of Mines

The Editor:

Sir—Referring to the editorial in your issue of the 20th instant, on 'Taxing Mines in London,' your readers may be interested to know that similar taxation is proposed in Australia. A bill known as the War Time Profits Tax Assessment Bill was tabled in the House of Representatives by the Commonwealth Treasurer in May last, but was shortly afterward withdrawn for further consideration in consequence of representations that were immediately made to the Minister by representative mining men and others as to the unfair incidence of and far-reaching effects to be anticipated from the proposed taxation in certain cases and in certain ways such as those to which you refer. The bill, which has since been re-drafted, is to be debated by Parliament in March next and is expected to become law during that month. Meantime, as a result of the further consideration given to its provisions and as a result also of the representations made, the Government has announced that gold mining is to be excluded from the incidence of the taxation and that it is proposed also to introduce other modifications to meet, to some extent at least, the special case of the mining industry, particularly new mines.

It may also interest your readers to learn that one of the Australian companies mining for tin in the Malay Peninsula has recently transferred its place of incorporation from Australia to the Federated Malay States, and further that another Australian group that proposes to equip a tin mine in Bolivia is arranging to incorporate the undertaking in the United States.

W. A. FREEMAN.

San Francisco, January 22.

ALUMINUM WIRE as a substitute for copper in electrical transmission of power has been adjudged as unsatisfactory. Aluminum is a good conductor of electricity but to secure equal efficiency the sectional area of the aluminum wire must be much larger than that of copper to carry a given current. Moreover, the aluminum wire has been found to crystallize from the swaying of the wires in the wind, which causes them to break. Several aluminum-wire lines, constructed at great expense, have been replaced by copper, the aluminum being re-melted into bars for manufacturing into other articles.

BURMA is the largest producer of tungsten ore in the British Empire. The production in 1915 was 2645 tons of wolframite. It is expected the output soon will reach 4000 or even 5000 tons annually.

Gold and Silver Mining in Chihli, North China

By A. B. Wheeler and S. Y. Li

CUPELLATION FURNACES

CONCENTRATING SILVER-LEAD ORE

CRUSHING MILL

DRESSING-FLOORS

Chihli is the northernmost of the 18 provinces of China proper and lies partly within and partly without the Great Wall, which zigzags across it in a north-westerly direction from Shan-hai-kwan, a small watering place on the Peking-Mukden line of railway near the port of Ching-wang-tao on the gulf of Chihli, west of the town of Kalgan. This place marks the entrance to the pass leading up to the Mongolian plateau and lies on the trade-route followed by the picturesque camel caravans which come from the north to Peking during the winter season. An inner rampart branching from the Great Wall about 40 miles north of Peking traverses the province in a south-westerly direction until it reaches the boundary of Shansi province, where it again forks, one arm going westward and rejoining the Great Wall in North Shansi, thus forming a loop, and the other runs southward marking the boundary between the two provinces.

The area of the province is approximately 116,000 square miles, or slightly less than that of the British Isles, and the population has been estimated at 21 millions. Northern Chihli, or that portion of the province lying north of the outer Great Wall, covers rather more than half this area, but it is sparsely inhabited in comparison with the southern half.

The climatic conditions present the extremes of an excessively hot summer, with torrential rainfall in July and August, and a bitterly cold winter with ice-locked ports. The normal range of temperature is from 105° to 0° F., the pleasantest months being May, October, and November. The late winter and early spring months (February to

April) are marked by persistent winds and appalling dust-storms from the Gobi desert.

With the exception of the special administrative area of Cha-ho-er, embracing Kalgan and district, North Chihli is administered by a Military Governor quartered at Jehol or Cheng-teh-fu. This was the ancient capital of Mongolia and the place where the Emperor Chien Lung, in the middle of the 18th century, built a beautiful imperial palace which was used as a summer residence by the court until 50 years ago, and also where the Macartney mission was received in 1793. In the neighborhood are some fine Buddhist monasteries and pagodas, notably the Buddha-la, said to be a replica, on a small scale, of the Llamaserai, in Thibet. But "the glory has departed," both palace and monasteries are rapidly decaying, and were it not for the garrison the place would sink into insignificance.

The chief commercial centre of North Chihli is Chih-fêng (Chinese name) or Wu-lan-ha-ta (Mongol name, usually abbreviated to Ha-ta). It lies 140 miles north-east of Jehol by road and can boast one of the largest grain and beef markets in North China, and the second largest horse-market. It does a thriving trade in flax and hides, and there are numerous distilleries for the manufacture of millet spirit in the neighborhood.

The railways of China may be said to radiate from Peking. These are the Peking-Mukden, connecting with the trans-Siberian route to Europe; the Peking-Hankow, on which is situated Pao-ting-fu, the old provincial capital; the Peking-Ta-tung fu, passing through Kalgan, and the Tientsin-Pukow joining by ferry across the Yangtze river with the Nanking-Shanghai railway. North Chihli possesses no railways; all transport is by cart or pack-animals over atrocious roads or by the few rivers that, during the summer months when water is high, will permit the passage of light shallow-draught native craft. These are 40 ft. long by 8-ft. beam, draw up to 12 in. of water, and can carry two or three tons of cargo. They travel rapidly down-stream on the swirling current and have to be towed laboriously up-stream by a gang of coolies or trackers.

While the cost of both road and river transport varies greatly, depending largely on the season and the bargaining ability of the hirer, some figures may be quoted to give a general idea of the expense. On the Lan-ho river from Jehol to Lanchow (on the Peking-Mukden railway) a distance of 170 miles, native boats carrying 4000 *catties*¹ can be hired at ₧15 for the trip,² which takes from 3 to 5 days, depending on the state of the water. This corresponds to 10s.4d. per ton of 2000 lb., or 0.75 cent per ton-mile. Traveling up-stream, the rate and the time taken to complete the trip are about double.

From Chin-chou, on the Peking-Mukden line, to the Chuan-shan-tze gold mine, a distance of 180 miles by road, the cost of transport is ₧120 per wagon-load of

4000 to 5000 lb., or £4 17s. per ton of 2000 lb., or 13 cents per ton-mile, while the ordinary small Peking cart, capable of taking 500 to 600 lb., and drawn by two animals harnessed tandem, can be hired at ₧22 for the trip. After traveling over the roads in North Chihli, if indeed a boulder-strewn river-bed can be designated as such, one thoroughly understands the reasons that prompted the design and structure of the Peking springless cart.

While on the subject of travel, a word of warning must be given, for the benefit of the uninitiated, about Chinese inns. Don't stay at one if you can possibly avoid it! The interior of China, in this respect at least, differs but little from the England of Chaucer's day. If unavoidable, and this is often the case, especially in South China, be armed with a plentiful supply of strong disinfectant and apply it liberally. A temple, school-room, or part of a private house is often procurable by sending a fore-runner, and affords welcome relief. In North China a suitable spot for a camp can usually be found when the halt is called, but this is not often the case in South China, where the land is so closely cultivated. Wherever he may be, the foreigner traveling in the interior must make up his mind to dispense entirely with privacy; for, apart from the fact that the inn is to all intents and purposes a common-room for all sorts and conditions of men (and vermin!) he will find that, whether sleeping or waking, eating or drinking, bathing or dressing, he affords a never-failing object of interest to a swarm of villagers, who apparently regard him in much the same way as does a bank-holiday crowd the animals in the Zoo. But one must in justice acknowledge that, apart from their inordinate curiosity, the crowd is usually extremely well-behaved, and if the foreigner can turn the joke against one of them he will instantly win their goodwill and favor, for the Chinese have a large fund of good humor.

GEOLOGICAL FEATURES. The complexity of the geological structure of the mountain region of North Chihli is such that many years of arduous work would be necessary before anything in the nature of a reliable geological map could be presented. In general terms, however, it may be stated that the main features consist of a basal complex of schist, gneiss, and highly metamorphosed rocks of probably both igneous and sedimentary origin, which may be classed as Archean.

Overlying these unconformably, and often showing a high degree of metamorphism and folding, is a great thickness of limestone, quartzite, and schist, the first named predominating and forming the ore-carrier of the principal mineral deposits. Both these systems have been intruded by acid igneous rocks. Following this, and belonging to a much later period, is another series consisting principally of limestone, with sandstone, shale, conglomerate, and igneous sills. This formation is found principally as outliers, and contains coal seams that are worked at numerous places.

On top lies the 'loess,' that remarkable sub-aerial deposit of northern and western China, so often obscuring the rocks of both hill and valley. It weathers into fan-

¹A table of Chinese weights and their Anglo-American equivalents is given at the end of this article.

²We use the 'peso' sign to indicate the Mexican dollar.—EDITOR.

tastic ridges or deep ravines with vertical walls that stand well, and the poorest class of Chinese takes advantage of this to excavate cave-dwellings. As agricultural land it is moderately productive, but it is continually being washed away, choking the rivers and slowly modifying the coast-line of the Gulf of Chihli.

GOLD MINING. The wide-spread occurrence of gold is

which the boulders and gravel are raked out and the dirt carried to the water and panned. Although probably most of the gold was, and still is, won from the alluvium, in no instance under our observation had bed-rock been touched. This is doubtless due in most instances to the depth to bedrock and to the fact that alluvial mining is carried on by individuals of the poor-

amply indicated by the numerous old workings scattered throughout the more mountainous districts. Work is still done in a spasmodic and desultory manner at many points, and the alluvial deposits in the river-beds and valleys are also worked by the farmers in the off season, when no other work is obtainable, 40 cents (Mex.) per day being considered abnormal earnings. The alluvial workings consist of small holes in the river banks, from

est class who are totally unable to cope with the water; even were they financially able to do so, it must be remembered that the Chinese rarely expend any appreciable amount of capital on mining work for which they cannot see a good prospect of immediate return.

Hoover records³ the discovery of a drainage-tunnel in

³Metal Mining in the Provinces of Chihli and Shantung, Trans. Inst. Min. & Met., 1900.

bedrock at the Chin Changkuo Liang mine, but this would appear to have been of ancient Korean origin. This property, which is 25 miles north of Chao-yang, was worked for both vein and alluvial gold, the latter being by far the more profitable, but work was abandoned many years ago, though a little washing is still occasionally done.

Many of the small mines, both those abandoned and now in operation, are quartz veins of the pegmatitic type, segregations of quartz in veinlike form in granitic or gneissoid rock, or contraction-fissures. Where these attain a reasonable stoping-width they are usually barren, and where narrow, or consisting of a series of thin stringers, are extremely patchy; they almost invariably pinch out or merge into the country-rock at comparatively shallow depth—a common experience with this class of veins.

Where the country-rock is limestone the vein is generally more persistent, and the gold is usually associated with galena and pyrite.

The principal gold mine now working in North Chihli is the Chuan-shan-tze, 50 miles south-east of Ha-ta. The formation is limestone intersected by dikes of granite. In the hills surrounding the mine there are at least ten lines of ancient workings, some of which extend for a distance of over 1000 ft. on the strike, but as they have not been worked for the last 30 or 40 years, and are now inaccessible, nothing is known as to the gold contents of the ore. The present operations are confined to an ore-body having a north-west strike and dipping 65° north-east. This is apparently a fissure-vein, though the walls are in places so poorly defined that it has rather the characteristics of a mineralized channel or impregnation, indicating subsequent metasomatic action.

The workings extend over a length of 900 ft. and to a maximum depth of 600 ft. The three main openings can hardly be dignified by the name of shaft, since they follow a zig-zag course downward, with drifts or stopes as is convenient. The width of the stopes averages three feet. They are invariably carried underhand and the working-faces, of which there are rarely more than two or three, are generally the deepest places in the mine. This is in accordance with Chinese practice, which consists in working out all the pay-ore as fast as found without ever a thought of creating a reserve.

The vein exposed in the three working-faces is a well-mineralized body of ore about three feet wide intersected with veins of calcite and carrying galena, iron, and copper pyrite, and occasionally mispickel. The ore is rough-sorted underground and carried up in baskets to the nearest windlass, often a distance of 200 ft., whence it is hoisted in three stages to surface.

The small amount of water is raised by hand-pumps in four lifts. Windlass and pump-men are paid ₧4 per month and work 6-hour shifts, on and off.

All dead-work, driving and winze sinking (4 by 6 ft.) is paid for by the company at ₧9 per foot.

The explosive used is black powder of local manufacture and costs 60 coppers per catty, say 15c. per pound;

the miners work single-hand, usually putting in a 15-in. hole, which is charged with four ounces of powder.

The method of ore-treatment is as follows: The fine is concentrated in a small washing-plant near the shaft-mouth before being sent, together with the coarse, to the mills. The waste, discarded by the miners underground, and the tailing from the fine, is carefully re-sorted by boys before final rejection. This ore is broken by hand to about walnut size and is then dried on galvanized-iron sheets over a fire; this is not done with the object of roasting, but to render it brittle for crushing.

The crushing-mill consists of a cylindrical granite-roller rotating about a vertical wooden shaft fixed in the centre of a slightly basin-shaped granite base. The roller-axes are set centrally in a rectangular wooden frame, which is fixed slightly eccentric to the vertical shaft; the result being that a considerable grinding effect is produced when rotating. This action is strongest at the apex of the granite base, which is of harder rock than the roller, so that the latter takes most of the wear. When worn at one end it is reversed. A roller lasts from one to three months. The mullers are dragged round by ponies harnessed to poles, which are extensions of the side pieces of the frame. The ore is crushed dry and is fed by hand around the vertical spindle. The dimensions of the larger mills used for coarse crushing are roughly: base, 6 ft. diam. by 10 in. thick at outer edge and 13 in. at centre; roller, 30 in. long by 21 in. diam., set about 6 in. out of centre with the vertical spindle. The capacity may be taken at about 600 catties (about 800 lb.) per 24 hours, reducing to 10-mesh.

The dry-crushed ore is removed from the mill, mixed with water, and taken to the dressing-floors. These consist of a series of pairs of tables, or sluicing-down boards, about 6 ft. long by 2 ft. wide with 5-in. free-board and set at 10 to 15% slope. A layer of pulp about two inches thick is placed at the head of the table and water allowed to percolate over it. The dresser then starts working it over, raking down a little at a time, until he has completed the whole layer, the bulk of which is retained by a V-trough at the lower end of the board. He then rakes this up again and forks it over afresh, the tailing from this first washing being run to waste.

It is then shoveled onto the platform between a pair of tables and receives a similar treatment on a second table. The overflow from here is collected and re-ground in a small roller-mill and again passed over the tables.

The above process is repeated on an average four or five times and occasionally as often as ten, until a sufficiently high-grade concentrate has been obtained, with a reduction in bulk to about 1% of the original picked ore. It is finally panned down by hand to obtain the free gold, which is smelted into bullion running about 800 fine.

The tailing from the floors is repeatedly re-treated by outside workers, or 'streamers,' who are said to be able to earn up to 40 cents (Mex.) per day, it being stipulated that the concentrate shall be sold only to the company.

The mine is operated on a tribute system; the con-

ROASTING-KILNS AND SMELTING FURNACE

THE BUDDHA-LA MONASTERY, JEHOI

tractor both mines and dresses his ore, providing all the necessary labor, tools, explosives, and lights. The company hoists the ore to surface, does all the pumping, provides all the timber, which has to be placed by the contractor, supplies the mills and animal power, and dressing-plant, and buys the gold from the contractor at ₧15 to ₧20 per *liang*, or roughly at about one-half its value!

The output in 1913 and 1914 was about 130 oz. per month, or just about sufficient to meet expenses; in 1915 it rose to about 250 ounces.

It is certain that a considerable amount of illicit gold-buying takes place, which is not surprising under the circumstances, despite the fact that precautions are taken to guard against it.

There are no reliable statistical data as to the output of gold from North Chihli, but it is safe to say that it is well under 10,000 oz. per annum and probably does not exceed 7000 ounces.

SILVER MINING. The silver produced in North Chihli is all obtained from deposits of argentiferous galena, which are found either in the form of quartz veins in granite, or as replacement-deposits or fissure-veins in limestone.

The former type of lode is being worked at the Yü-cheng company's four mines in the Hsiao-hei-kou, Lung-hua magistracy, 30 miles north of Jehoi, and 12 miles west of the town of Huang-ku-tun, which is on the Yi-shun river, a tributary of the Lan-ho. At high-water shallow-draft boats can reach this point, but Jehoi is the normal head of navigation.

The veins often show a pegmatitic structure. They are narrow and extremely erratic, and the galena occurs in them in small stringers and bunches. The output from these mines is meagre, and their capacity for production is limited.

The deposits in the limestone are larger, and from these the bulk of the silver output has been, and still is, derived. The principal mines are the Yen-tung-shan, Ku-shan-tze, and Yang-shu-lin, in the Jehoi mining district, 30 miles north-east of the town of that name.

The first-named is a fissure-vein with an east-west strike and a dip of north 75° ; it is traceable for over five miles and workings are found at numerous points along it.

The enclosing rock is limestone, in places highly metamorphosed, and the deposit occurs near a fault-contact with schistose rocks, both formations being greatly disturbed by acid-igneous intrusions. No igneous rock was actually observed, however, underground.

The mine is now being worked by a low adit driven east for 1250 ft., giving 800 ft. of back, which, however, is honeycombed with old workings and for the most part exhausted. A second adit, known as the Lo-to-po mine, driven on the same lode but some distance east of the above, is also being worked, the ore at both places being mined below the adit-level.

The galena occurs in association with blende, usually as a stringer or vein a few inches wide, opening here and there into small bunches and pockets of ore, though occasionally a lens containing several hundred tons of high-grade ore is found, affording periods of prosperity in an otherwise feeble exploitation.

The Ku-shan-tze mine is about six miles east of Yen-tung-shan and was worked for a few years, about 1888, under foreign (American) technical control, but proved a failure, owing, it is stated, to the loss in concentrating and to the high price of fuel. Chinese methods were then reverted to, steam-pumps being used to handle the water, which is reported to have been considerable, the depth of the workings being 850 ft. Finally the lower levels were abandoned and the water rose to the 170-ft. level, where it now stands.

The old stopes above this show that the orebody is a typical replacement deposit in limestone and consists of a series of roughly parallel irregularly shaped masses, which are reported to unite in depth and continue as one body below the 260-ft. level. The present output is being obtained by following the numerous small veins and leaders of calcite, usually less than six inches wide, and carrying finely disseminated galena with stringers and occasional bunches of ore. These form connecting links or channels between the larger deposits. They can only be regarded as the remnants of the once extensive orebody, though it is stated that the deposit has by no means either pinched out or been worked out below water-level.

The Yang-shu-lin (or Pang-chia-ko) mine lies about 15 miles north-west of the former. It is, like the Ku-shan-tze, a deposit of metasomatic origin, the ore being galena

associated with blende in a calcite gangue. It is irregular in shape, the orebodies, great and small, ramifying in all directions, and connected by small leaders of ferruginous calcite, often barren, but now constituting the only available source of ore. The old workings cover a distance of about 350 ft. and extend to a depth of 250 feet.

All these mines are worked on a tribute system arranged as follows: The headman of a 'chore,' consisting of seven men, selects a 'pitch.' This is a working-face about 60 ft. long; and in the selection of these it is a case of 'first come, first served.' He then makes a contract with the office-men or mine-officials, being required to find an approved guarantor, if not possessing sufficient means himself. The contract binds him to confine his mining to the working-face assigned to him and to carry on work there continuously under pain of forfeiture should he fail to do so for a longer period than half a month.

Of the silver produced, the company first takes its tribute, which amounts to 10% on a total output not exceeding 500 *liang* (or 600 oz.), 15% on a total output not exceeding 1000 *liang* (or 1200 oz.), and so on, 5% being added for each additional 500 *liang* up to a maximum of 30% tribute on 2500 *liang* or more, always reckoned on the aggregate of silver produced by the tributer while working the mine.

The guarantor then takes his 10%, after which deduction is made for smelting charges (fixed), tools, or any supplies, including advances and food, and the balance is divided among the party, the head-man receiving twice as much as the others.

If the ore is poor the company may agree to accept less tribute, but in practice the tributer is charged with sundry extras that bring the amount up to the company's regular figure.

The following is a copy of a tributer's account.

CHENG PING WESTERN OFFICE

Kung Fa party.

Taels

(1 *tael* = $\text{¥}1.44$)

One ingot of silver bullion weighing 73.26 <i>liang</i> (87.91 oz.) at 960 fine.....	70.32
Less company's tribute of 20%.....	56.25
Deduct: Smelting charges, 10%.....	5.63
Tools	1.62
Advance	0.14
Water money (repairs, power and water)	1.47
	8.86
Balance due	47.39

The company usually pays for dead-work in limestone at the rate of 1.5 *taels* ($\text{¥}2.2$) per foot, whether driving or sinking. The tributer builds his own smelting-furnaces with material supplied, and does his own smelting, using charcoal for fuel, costing 5 *taels* per 1000 *catties* (25c. per 100 lb.). The company employs numerous watchers to guard against theft of ore or bullion.

Historical records show that the smelting and refining of silver has been conducted extensively in China for

centuries, and it is probable that the methods at present practised have undergone but little alteration for several generations. The appliances used are shown in the accompanying illustrations and a description of the process is as follows:

The ore is rough-sorted underground and then cobbled and close-sorted at surface. The waste and fine are concentrated by washing in scoop-shaped wooden dishes.

The roasting is conducted in kilns, of 5 to 6 ft. diam. by 3 ft. high, with a discharge opening, and built of sun-dried brick, having staggered vent-holes in alternate tiers. The ore is packed in layers two or three inches thick with charcoal between each bed, on a bottom layer of firewood, which is then lit, and the charge allowed to burn out. In the case of high-grade concentrate two such roastings, requiring three days to complete, may be given, or where the galena content does not exceed 50% the process may be omitted entirely. The roasting is far from being uniform and part of the ore is generally found to have been fused, or reduced to metal, while other pieces are merely burnt superficially. When the kiln is discharged these latter are picked out and added to the next charge. The charcoal consumption varies from $2\frac{1}{2}$ –1 of charcoal to 1 of ore.

The smelting is done in beehive furnaces built of brick smeared with mud. The dimensions are about 3 ft. high, 2 ft. diam. at the hearth, and 1 ft. at the throat; a tuyere for the blast (supplied by a double-acting Chinese bellows) and also a tap-hole, are built in; the hearth is of compressed wood-ash and a swell, or 'belly,' in the furnace keeps the tuyere free, helps to distribute the blast, and holds up the ore in the reducing-zone. The flux used is old cupel-bottoms or wood-ash impregnated with litharge; the fuel is charcoal, the consumption of which varies from 6 (or less) to 1 of ore. It is added with the ore, about 10 lb. at a time, until the capacity of the furnace has been reached, which is usually about 130 lb. The blast is continued for two hours, when the dense sulphurous fumes given off at the start have ceased. The slag is then tapped and the furnace cooled after a brief interval by a douche of water, to be broken down and carefully sorted over.

The cake of lead is hammered free from slag, and cupelled on an oval hearth built of wood-ash compressed by foot and scooped out to the required shape. On this the lead-cake is placed, and a muffle of brick plastered with mud is built up on it. Charcoal is heaped over this and fired, and the whole is covered by a dome of brick plastered with mud; a circular opening is left at the top for feeding fuel, and the mouth of the muffle is closed against draughts by a brick. The charcoal consumption is 4 to 1 of lead-cake and the cupellation takes about 10 hours to complete. When the finishing-point is reached, after 'flashing,' a green stick is passed lightly over the surface several times and a gentle air-blast is blown into the muffle. This removes the impurities. The silver quivers and glows, showing solidification. It is then cooled off, and the furnace is broken down and carefully sorted over.

The silver thus produced will run 980 fine, and after weighing, is re-melted and either cast into *sycee* or 'shoes' of about 60 to 70 oz., or into buttons of 6 to 7 oz., these being alloyed with 2% of copper.

The fineness of silver (and also of gold) is estimated by its appearance and cut, and the degree of accuracy attained by those whose business it is to value *sycee*—this is monopolized by a few families that have done it for generations—is remarkable; they can judge it to within one or two millièmes.

The annual output of silver from the mines in Chihli has declined heavily during the past 20 years. Hoover gives it at 140,000 oz. in 1898, whereas it does not now exceed 30,000 oz., if indeed, it reaches that figure.

Conversion of Chinese weights into British equivalents, as determined by Presidential decree of March 1914:

1 liang (or tael)	= 24 dwt. (Troy)
1 " "	= 1.31 oz. (Avoir.)
1 catty (or chin)	= 16 liang
1 " "	= 1.31 lb.
1 picul (or tan)	= 100 catties
1 " "	= 131.6 lb.
1 " "	= 0.0587 long tons
1 " "	= 0.0658 short tons

Exchange fluctuates widely; it has here been taken at ₧11 to the £1; at which ₧1 = 21.82d. The Mexican dollar exchanges locally for 120 cents silver or 135 coppers. The tael—dollar exchange may be taken at T1.69 = ₧100.

Molybdenum

The early expiration of the Halcumb patent, held by the Crucible Steel Company, which practically controls the use of molybdenum in the United States, renews interest in those concerns producing this modern steel alloy, as it places them in a position to obtain a better market for their product.

Molybdenum alloy used by the Krupps, increases the life of rifled guns, giving the steel a hardness that no other alloy, not even tungsten, produces. The use of it in the United States has been restricted by the blanket patent which the Crucible company has held.

The chief production of molybdenum in America comes from Canada, the most valuable properties being in Ontario. Here recent discoveries of the ore, such as the mine of the Steel Alloys Corporation at Renfrew, make it possible for the United States to obtain supplies both for ordnance and industrial use.

COAL RECOVERY in the anthracite mines of Pennsylvania is stated to be about 65%. This means what at present appears to be an unavoidable loss of 35% of the coal due to mining methods and handling. The cost of production is an important factor in the causes for this heavy loss. If the coal operator could demand a higher price for his coal without increasing the cost of mining it, undoubtedly the loss would be correspondingly reduced.

Cost of Mining in Yukon Basin

The cost of mining is always interesting, particularly in regions at a distance, and where unusual conditions prevail. The Canadian Department of the Interior has recently issued a publication describing the Yukon Territory, in which is given the cost of mining in the Yukon Basin, and from which the following is abstracted: The cost of a complete pumping, thawing, and self-dumping equipment for working ten shovels, designed especially for the Yukon, to serve as a light and simple machine to hoist and convey dirt from a shaft or open-cut to the dump, or sluice-box, is \$3205. The cost of sinking a shaft 8 by 8 ft. to a depth of 30 ft. by the self-dumper is stated to be \$9.16 per foot. When a shaft of the same size was carried to a depth of 55 ft., hoisting with windlass, the cost was \$9.96 per foot. Tunneling by self-dumper, 6 by 6 ft., cost \$6.44 per foot. The cost of thawing, hoisting, and sluicing over 590 sq. ft. of bed-rock where the gold-bearing gravel removed was three feet deep was \$179.75 or 30c. per sq. ft. of bed-rock. The working-cost of a self-dumping plant having a capacity for handling the gravel on 600 sq. ft. of bed-rock, three to four feet deep, was \$189.38 or 31c. per sq. ft. of bed-rock. Two men thaw and take out six feet of dirt in a shift of 10 hours. One cord of wood will make steam sufficient to thaw a shaft 30 ft. deep. From the bottom of a shaft two men will thaw and drive 3½ ft. in a drift 6 by 4 ft., and hoist the gravel with a windlass in one shift of 10 hours. The cost per foot is \$2.50. On Bonanza, Hunker, and Eldorado creeks, in one season, 5,133,575 cu. yd. of gravel was dredged, producing \$3,343,667, at a cost of 29.53c. per cubic yard. This included depreciation. Of the area dredged 68.4% was frozen and had to be thawed by steam. The cost of drilling frozen ground for testing the gravel ranges from \$1.73 to \$2.36 per foot. The cost of hydraulicking 3,241,642 cu. yd. of gravel, with a total of 538,905 twenty-four hour miner's inches of water that gave a duty of 6.02 cu. yd. per miner's inch was 12.6c. per cu. yd. The total area of bed-rock cleaned was 126,057 square yards.

DRIVING a tunnel beneath the English channel to connect England and France is a matter once more being agitated in England. Two important, though conflicting, considerations are being advanced: The advantages of such a tunnel on one hand, and the risk of having such a means of communication in the event of a war. Those favoring the tunnel insist that should peace last a hundred, or even fifty years, after the close of the present War it would fully justify the construction of the tunnel, and in any event, there is no doubt that the advance in scientific knowledge would make it possible to hold such a means of communication open against any enemy.

'HUMAN MORAINES' is the term applied by an English writer to the great piles of placer-tailing he saw in the diggings of the Klondike and the Yukon goldfields. It seems not inappropriate.

Flotation of Molybdenite

By **Stuart H. Ingram**

During some recent work on molybdenite ore a flotation-machine was developed differing from any that have been described, and while its field of usefulness is limited it has some interesting features. The ore contained 10% of molybdenite and small amounts of copper and iron sulphides in a gangue of quartz and calcite. The work undertaken made a clean concentrate necessary, so attention was directed to experiments on 'skin flotation,' as it was hoped that, owing to the flaky nature of molybdenite, it might be floated preferentially.

A test-machine was built; it consisted merely of a small spitzkasten one foot square at the top, an iron plate of about the same size, and a tub for catching the concentrate. Two opposite edges of the plate were turned up half an inch to form a wide launder, one end of which rested on the back edge of the spitzkasten in such manner that when the plate was inclined at about ten degrees from the horizontal, and the spitzkasten filled, the lower edge of the plate just penetrated the water's surface. The ore was mixed with oil and water and fed by hand along the upper edge of the plate. The irregularity of hand-feeding caused ripples at the point of entering the spitzkasten, and this undoubtedly sank much molybdenite, but still the results were encouraging enough to justify the construction of a larger machine on which the feed could be better regulated and distributed across the plate.

While experimenting, the best results were obtained when the pulp was very thick, but the thick pulp gave trouble through banking up on the plate. On the new machine the plate was suspended and given a reciprocating motion at right angles to the direction of flow by means of a shaft and eccentric. The results were better than with the first apparatus, with the stationary plate, but still left much to be desired. No matter how thin the sheet of pulp on the feed-apron was kept, some particles of molybdenite remained below the surface of the water during the entire transit across the plate, and on arriving at the spitzkasten they sank with the gangue. Riffles across the plate were tried, and while the eddies then formed brought some particles to the surface they sank enough of those already floating to nullify the effort.

I then tried riffles up and down the plate, or parallel to the flow of pulp, my idea being that the submerged particles would be thrown against the riffles by the motion of the plate and would eddy to the surface, where those with an oily coating would float. It worked beautifully. The riffles were spaced about two inches apart, breaking the plate up into a series of channels. Down the centre of each of these the molybdenite collected in a black streak forming a decided contrast in color with the brownish gangue, which seemed to hang close to the riffles, giving the table a striped appearance. Arriving at the placid surface of the spitzkasten the molybdenite floated out across it with considerable speed, the flakes in

front apparently pushed on by those coming after. It was not necessary to use jets of water or any other means to give a forward motion to the surface film.

The concentrate flowed over the lip and was conducted in a launder to a settling-tank while the gangue was discharged through the spigot. As the feed was a thick pulp a water-line was connected to the spigot so that the tailing could be diluted sufficiently to flow readily in the discharge-launder.

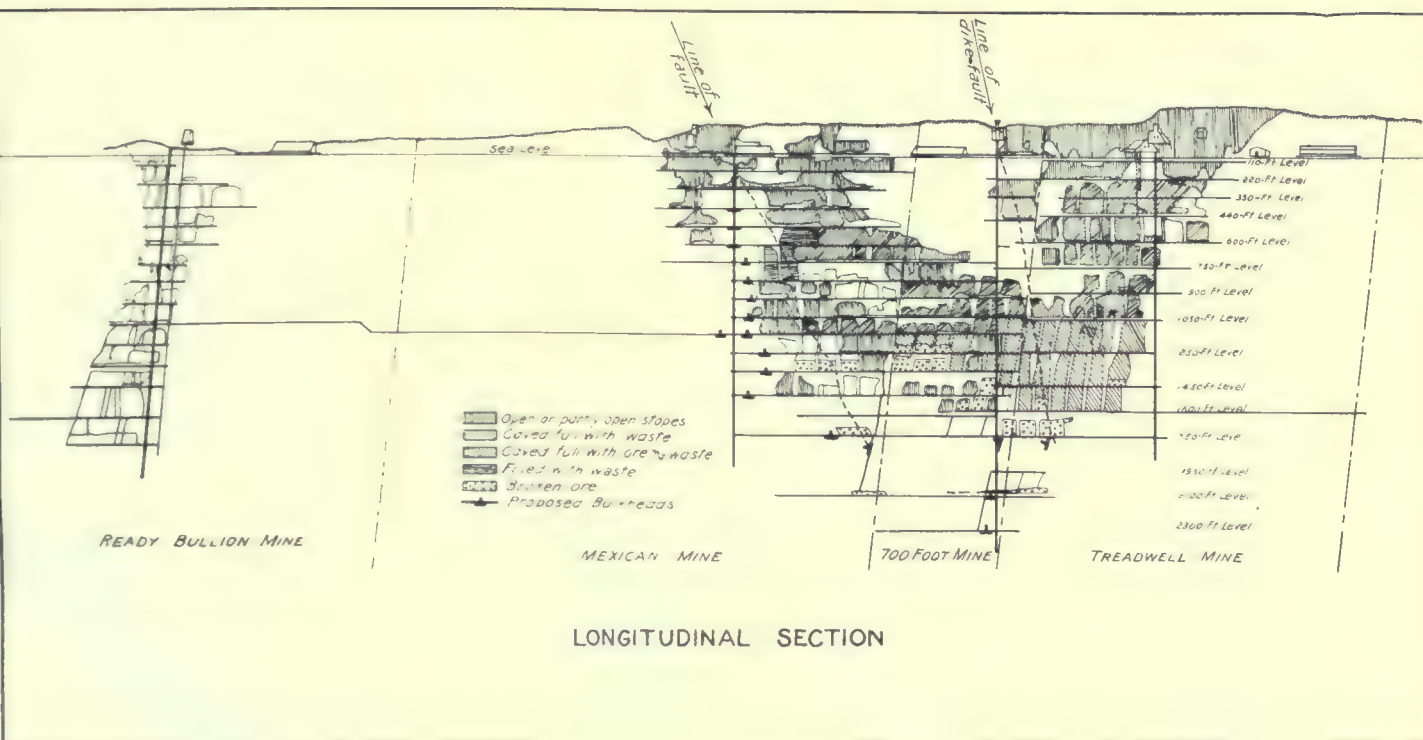

With care in regulating the feed, amount of oil, kind of oil, and size of spigot-opening, a concentrate was obtained that assayed 80% MoO_3 , or 89% molybdenite. The copper and iron sulphides were eliminated by a proper selection of oil, but I believe they could have been floated had that been desired. The machine had its weak points, for it did not do well on slime and the ore needed several treatments to ensure a high recovery. But on sand between 40 and 150-mesh, it did excellent work—a recovery of over 90% was reached. It worked best on a classified feed where the grains were of about the same size.

I believe the idea of placing riffles at right angles to the motion of the table as described is patentable, but as there seems to be plenty of patents on flotation processes and machines—also sufficient litigation—I prefer to give it to the profession and hope there may be some who will find it useful.

THE rise in the price of aluminum to three times its normal quotation has led to a series of experiments being made with a view to recovering the metal heretofore lost in the form of chips, in machining aluminum castings in automobile factories. Although only 60% of the metal recovery is commercially possible, the preventable loss is of considerable magnitude. In re-fusing the scrap metal two methods are employed. In the one the chips are kept just above the fusion-point, the globules being made to coalesce by hand puddling. This smelting is done in an iron pot heated by oil. The other method is by the use of a flux that dissolves the dirt, skin, and oxide, on the surface of the chips, producing clean globules that can unite. The flux used consists of 85% common salt and 15% fluorspar (20 to 30% of the weight of the chips) mixed with the chips before charging. This is done in a graphite crucible, as a much higher heat is required than in the former method.

A MAGNESITE DEPOSIT is being worked in Italy that is said to contain over 1,000,000 tons. The analysis of this ore is said to run: magnesium carbonate, 88.11 to 90.03%; silica, 2.06 to 3.4%; lime, 2.68 to 3.34%; and iron oxide, 1.60 to 2.30%. The material is made into refractory brick, and has replaced the magnesite formerly obtained in Greece and elsewhere.

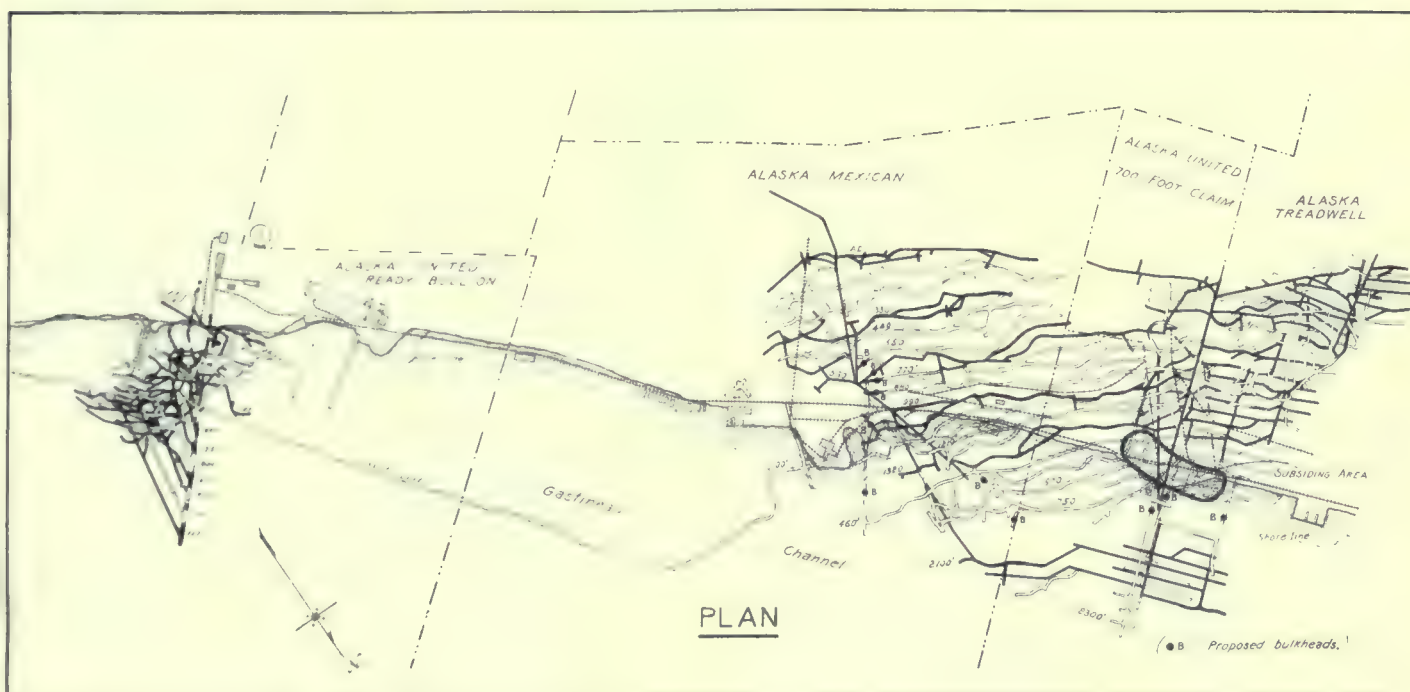

PIG-IRON PRODUCTION of Australia is now at the rate of 300 tons daily, this being the Broken Hill Proprietary's output. This is not the maximum demand of the Commonwealth.

The Subsidence in the Alaska-Treadwell Mines

For many years the gold mines on Douglas Island, Alaska, commonly known as the Alaska Treadwell group, have been recognized as being among the important gold mines of the world. The orebodies are of huge size and mining operations have been conducted on a commensurate scale, but by a method that has differed somewhat from that adopted in the exploitation of other large lodes. This variation of mining method has been the result of

economic necessity rather than engineering choice, for the ore of the Treadwell mines is of low-grade. The official report issued July 31, 1916, gives the total amount of ore crushed to date by all the companies of the group as 26,464,047 tons; the yield per ton, \$2.37; the mining and milling cost, \$1.42 per ton, including the operating cost of 95 cents per ton; and the dividends declared 80.5 cents per ton.

It is obvious that mines producing ore of a tenor so low as that at Treadwell require high-class management, and the adoption of methods of mining and metallurgy that will reduce costs to a minimum. The mines are situated on Gastineau channel, which separates Douglas Island from the mainland of Alaska. The dip of the formation and of the included ore-deposits is north-east, and the lower workings of the mines are vertically beneath this body of salt water.

The rocks enclosing the orebodies or adjacent to them are greenstone, slate, and soda-syenite. These rocks, when large excavations are made in them, generally stand fairly well without support. For many years the greater part of the ore was mined in large open pits called 'glory-holes.' Gradually, as the years passed, these open-cuts became increasingly deeper, shafts were sunk, and levels opened, far below the bottom of the surface workings. Glory-hole mining is one of the least expensive methods of winning ore, particularly from large orebodies, and it was found to be well suited to conditions on Douglas Island during the greater part of the year, but when the open-cuts became too deep to make this system safe or desirable, underground methods had to be adopted that would still admit the removal of a large tonnage of ore at the minimum cost. To follow the usual custom of square-set timbering, as practised at many Western mines, was prohibitive because of the cost, and the shrinkage method followed by filling with waste-rock from the surface, was not undertaken for a similar reason; so, after trying various methods a satisfactory system was evolved whereby a large tonnage could be mined safely and cheaply, and at the same time permit the recovery of the greater part of the ore. This system can be outlined thus: the opening of levels from the shafts, the removal of the ore by overhand stoping, and the leaving of pillars of ore, both vertical and flat, to support the walls and the back of each stope. The vertical pillars, reaching from wall to wall, were left at intervals of 100 ft., measuring from centre to centre. The flat, or sheet-pillars, were horizontal or nearly so. When a stope was being cut, the miners stood on broken ore, only enough being withdrawn at the level below to keep the men within reach of the back, which was arched to reduce the tendency to cave. Ore was stoped to a maximum width of 250 ft., and in places was removed for a width of 160 ft. along a horizontal distance of 300 ft. The shape and size of a stope was controlled to a great extent by the value of the ore—the mining stopped when the ore no longer yielded a profit.

Unfortunately, when the ore was drawn from the stopes the excavations were not filled with waste. As a natural result of this system of mining an enormous pressure gradually developed on the hanging-wall side of the stopes, and this pressure became concentrated upon the pillars left to support the ground. During the last five or six years this hanging-wall pressure has become increasingly evident, and numerous caves have occurred in the various stopes, some of them of a disastrous nature. Not only was the immediate neighborhood of the caving

badly shaken, but the terrific concussions, known as 'air-blasts,' caused damage at a distance, and frequently made themselves unpleasantly manifest at the surface.

Some of the earlier caves proved to be rather an advantage than otherwise, as a lot of waste rock from the walls and from the surface fell into the open workings filling some of them more or less completely, thus insuring against further serious caves at that locality, but where this broken filling did not break down into lower stopes the caving continued from time to time with increasing and alarming frequency.

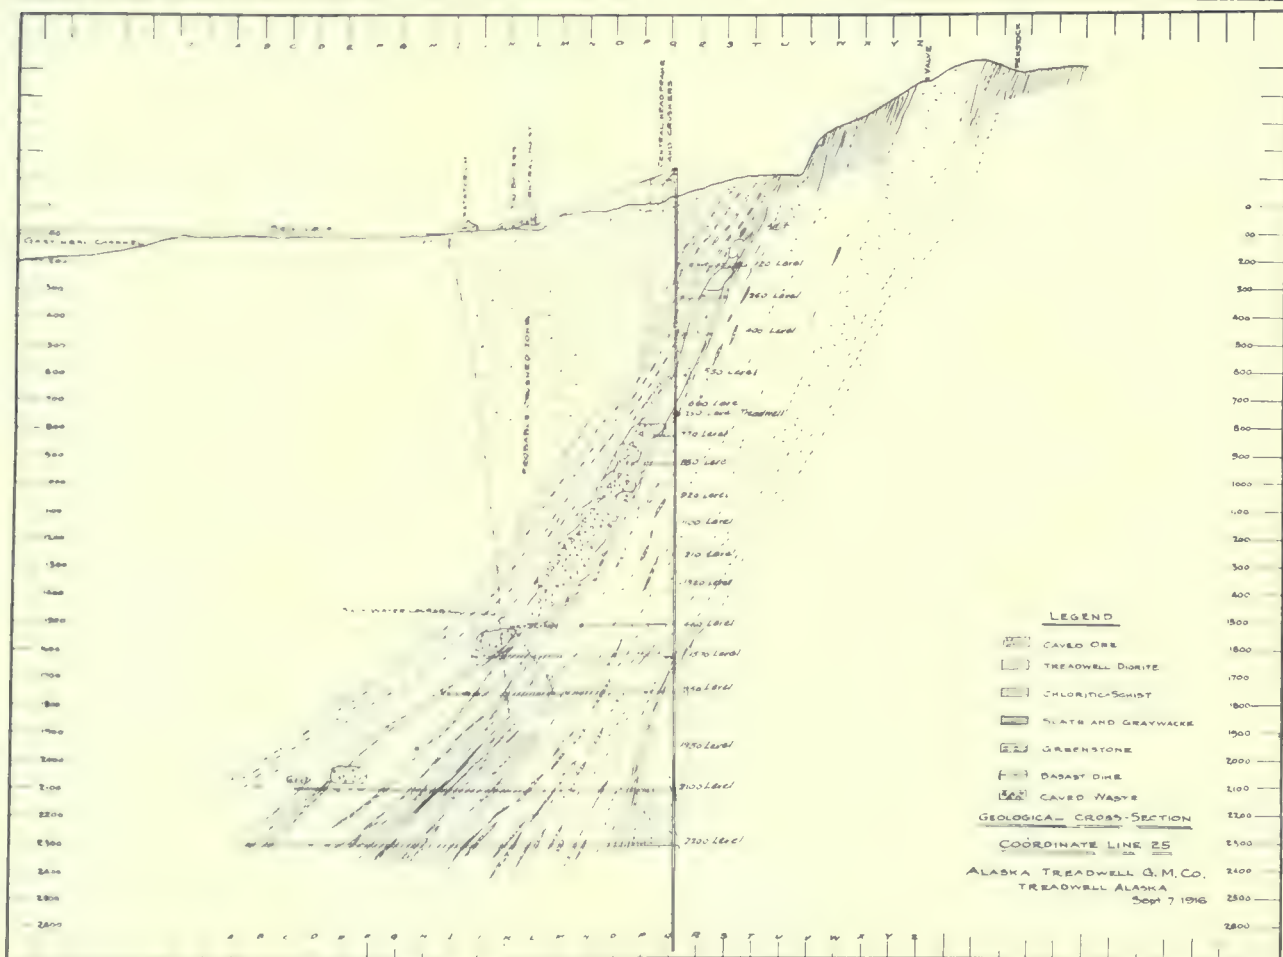

The following description of a large cave is abstracted from a recent official report* issued by the company.

"On June 15, 1915, the roofs of No. 2 and 3 south-vein stopes, above the 900-ft. level, caved-in, taking also the bottom of No. 3 and 4 north-vein stopes on the 750-ft. level. The pillar between stopes 2 and 3 north vein, 750-ft. level, no doubt went as well, as the cave reached to the bottom of the east end of the glory-hole, taking in all the loose rock, all our waste-dump, some slate in place off the foot-wall, and a little ground off the hanging wall. On July 2, the top of No. 2 stope, south vein, 750-ft. level, caved, and the stope filled itself with broken rock that had come down with the previous cave. This last cave left the floor of No. 6 level, above No. 2 south-vein stope, badly cracked, and this country now has the appearance of resting on the caved rock beneath."

The report proceeds to state that the first cave occurred between shifts, and no serious consequence ensued, though the air-blast was terrific. Both of these caves shocked the whole mine to a noticeable extent and a number of cracks have appeared in different places. One of these shows for 150 ft. on the surface, crossing a ditch above the glory-hole. There was a vertical movement of several inches along this crack, and all the water then flowing in the ditch disappeared in the crevice, necessitating the construction of a flume. Another crack appeared near the Central shaft on the adit-level, into which the water remaining in the bottom of the ditch disappeared. The cracks in the 440 and 600-ft. levels, near the Treadwell shaft, are of more consequence and may have an important bearing on the future of the mine. In fact, owing to these cracks, plans for sinking the Treadwell shaft to the 2100-ft. level have been abandoned. The No. 4 stope, north vein, on the 600-ft. level, is carried up to the 440-ft. level and is within 30 ft. of the shaft, between these two levels, and for this ground there is reason to fear. To forestall any further movement there, connection was made from the 330-ft. level to the bottom of No. 9 pit at the surface, and through this connection waste-rock will be drawn to fill the Oro stope, between the 330 and 440-ft. levels, and from this stope the rock will continue downward and fill No. 4 stope on the 600-ft. level.

Quoting the report: "On July 9 the bottom of the 1210-ft. Mexican level, over stopes 2 and 3, caved. This

*Report of the President to the Board of Directors, October 20, 1916.

was no surprise, as we have been for some time using every effort to hold up this portion of the Mexican mine. There were no serious consequences and there will be no interference with any of the Mexican operations."

These repeated caves in the underground workings began to show their effects with increasing distinctness at the surface, where a number of cracks developed. These became more pronounced as time went on, and an alarming subsidence of the ground became noticeable near the boundary between the Alaska Treadwell and the 700-ft. mines.

On July 27, 1916, a large crack was found in the north wall of the Central hoist-building and other evidences of disturbance began to be observed in various structures at the surface. Numerous cracks appeared in a concrete retaining-wall of the 700-ft. mill. Subsidence continued and on August 29 the line-shafting of the mill had separated over two inches. The foundations of the buildings and machinery settled, cracks opened and closed in the floors, and other evidences of subsidence became numerous during the summer of 1916. That some of these cracks appearing at the surface extended to points far below was proved by one developed 50 ft. east of the Treadwell shaft. This crack was in greenstone and was four or five inches wide. A stone dropped into it could be heard for some time rattling against the walls of the fissure as it fell. It was thought to extend at least to the 440-ft. level. When first noticed, in June 1915, this crack was but a quarter of an inch wide.

While there are many evidences of horizontal movement and of subsidence in places at the surface, and the Treadwell shaft has been pushed out of line in several places, the most significant evidences of movement are to be seen on the various levels of the mine near the Treadwell shaft and for some distance from it. Workings have caved, some places have been rendered inaccessible, and others are likely to become so. The 750-ft. level has been the scene of disastrous caves, and for 100 ft. from the Treadwell shaft all drifts except one are blocked, and constitute what one miner has described as a "wild-looking country." It was the bottom of this level that dropped in 1915, causing the bottom of the glory-hole to sink. Then part of the caved rock that reached the 750-ft. level flattened out in the stope like the lower end of a large rock-slide from a mountain-side; large boulders rolled into the drift, and four cars standing over the ore-pocket at the station were blown into the shaft. The force of the air-blast "shook the country around Treadwell like a small earthquake"—so says the report.

Underground, disturbances have taken place as low as the 1600-ft. level, and cracks have appeared in the 1750-ft. level, so that it will be seen that the movement of ground is by no means confined to the region of the upper workings of the mine.

What may prove to be much the most important matter in connection with this caving is the well-founded fear that the disturbance has not been confined to the area about the Treadwell and 700-ft. end-line, but may have

extended north-eastward into the hanging-wall region, and underneath the water of Gastineau channel. The caves in the mine are the direct result of mining millions of tons of ore in large blocks while leaving insufficient support in the form of vertical and horizontal pillars. Over 340,000,000 cubic feet of rock has been excavated. This naturally has resulted in a general subsidence over a large area and the formation of an intricate system of fissures on the hanging-wall side of the ore-deposits. If these cracks extend upward to the bottom of Gastineau channel, as now seems probable, and further movement ensues on the planes of these fissures, the consequence would be calamitous. There is one serious item of evidence bearing on this subject that is disquieting, to say the least, and that is that salt-water has made its appearance in the workings at a number of places, although not, as yet, in large quantity. Natural fissures—those that have been in existence for a long period are usually filled with clay or some other mineral that may have been deposited from solution, sealing the crack and rendering it water-tight; not so, however, a crack recently made, such as those resulting from conditions due to causes above described. Cracks of this description are likely to afford free passage to water and if they become numerous, under the hydrostatic head that would develop in the lower levels—1400 to 1700 ft.—the water would be likely to enter the mine at a rapid rate and under conditions that probably could not be controlled.

Following are some of the conclusions reached by the company's engineers in their investigation of the causes of the subsidence, as published in the report of Livingston Wernecke, geologist for the company:

"The surface subsidence between the Mexican and 700-ft. mills, which appeared in 1913, was preceded by caving of the stopes in the Mexican mine. A basalt dike with a decided fault, which cuts this ground diagonally to the strike of the slates and orebody, has formed a line of weakness by which the caving reached the surface. No undiluted salt water reaches the mine in this vicinity. The salt water seems to be diluted with an equal volume of fresh water, and to have traveled some distance through water courses.

"The surface subsidence in the vicinity of the Treadwell Club, Natatorium, Central Hoist, and 700-ft. mill is connected with the movements in the immediate bed-rock.

"The stopes in the Treadwell mine below this subsiding area are full of caved ore and caved waste, as far as can be determined by inspection.

"Underground investigations show that all pillars in the vicinity under consideration have been crushed. Some on the 1250 and 1050-ft. levels were mined so that they would cave. Those at 1450 and 1600-ft. caved without assistance, and some of those at 1750-ft. crushed while the stopes were full of broken ore.

"A reasonable conclusion from the above facts is, that the weight of overlying rock has broken the hanging

wall, and it is resting on the caved ore and caved waste. This is particularly likely to be true along the flat dips, and at the change from a steep to a flat dip, which forms a sag in the hanging wall. Part of the waste is from the glory-hole, and part from the hanging wall.

"Air-blasts, or the caving of rock with explosive violence from some internal or molecular strain, have produced a peculiar caving phenomenon from the backs of some stopes and faces of some drifts, but undoubtedly is not the cause of the intense shattering of pillars.

"The backs of cross-cuts and drifts are supported by an invisible arch-ring in the rock, the shape of which depends on the elastic properties, broken or fractured condition of the rocks, the dip of the formation, and weight of overlying rock. The amount that the axis of this arch-ring is inclined from the vertical depends on the dip of the formation.

"The backs of the stopes are supported by an invisible vault, which depends on the same properties of the rock as the above arch-ring. The inclination of its axis, also, depends on the dip of the formation.

"If all the stope-pillars are shattered, it is reasonable to believe that the fissile and broken condition of the slate, the steep and variable dip, the variable elastic properties of slate, diorite, and greenstone, and the cross-cutting dike-fault make an immense vault to span the entire area an impossibility.

"The axis of this theoretical cone will be inclined approximately 20° from the vertical toward the north-east, and will intersect the 700-ft. dike-fault. It is reasonable to conclude that the slate has broken along this cross-cutting line of weakness and reached the surface, where the subsidence has taken place.

"The 700-ft. mine dike-fault, which is similar in every way—except the one difference mentioned below—to the Mexican dike-fault, was first noted in May 1913 on the 990-ft. level of the 700-ft. mine.

"A severe cave followed in October 1913 in the stopes in the vicinity, from 1320 to the 880-ft. level. This was the origin of the present subsidence, which, after being augmented by further caving in June 1915, in the Treadwell mine, reached the surface in July 1916.

"The 700-ft. dike-fault differs from the Mexican dike-fault in that undiluted sea water flows along or near it, and enters the Treadwell mine on the 1600-ft. level."

The management of this group of mines has been watching the result of the earth-movements and the inflow of water, and the volume of the mine-water is being measured carefully and systematically. Many analyses have been made to determine what proportion of the water is entering from the Channel. Investigations have led to the belief that comparatively little sea-water entered the mine before 1916, but during that year the inflow of salt water is estimated to have reached 39 gallons per minute. Whether or not this flow will become greater remains to be seen, but it is feared that it may. Several lines of weakness cross the formation and the orebodies, in the form of dikes and faults, and it is

from these that the greatest danger is apprehended.

The consensus of opinion of the engineering staff of the mines is that further drawing of caved ore will cause more surface subsidence, and a probable increase of salt water, but if the drawing proceeds with caution, and all indications are carefully watched, no disastrous flood of salt water will follow.

Four preventive measures have been suggested: (a) Bulkheading each level near the Combination shaft, drawing the available caved ore, and letting the upper part of the mine fill; (b) Filling all open stopes above the 1750-ft. level with tailing, to prevent further caving; (c) Prospecting for the dike-fault at the surface, and building a coffer-dam or bulkhead to exclude all sea-water and fill it with tailing; and (d) Filling Gastineau channel 300 ft. or so from the present shore-line with tailing to exclude a part of the sea-water and prevent any possible flood from the Channel. The last is being done at present, and this, with careful drawing of caved rock should minimize the probable danger.

Although the quantity of water pumped from the Treadwell mines is small as compared with some mines, 27% of it is salt water from Gastineau Channel. This, with the surface subsidence near the shore along a line of structural weakness, is sufficient to constitute a menace if the drawing of ore had continued at the rate of 1,000,000 tons per year. This condition has been eliminated temporarily by decreasing the amount of ore drawn.

F. W. Bradley, president of the several companies, in his official report to the boards of directors of the Alaska Treadwell Gold Mining Company, the Alaska Mexican Gold Mining Company, and the Alaska United Gold Mining Company says: "If the properties are consolidated; if the orebodies continue down to the 4200-ft. level, of past average size and value; if the temperature at the 4200-ft. level does not exceed 95° F.; and upon the further assumption that stoping can be done on the basis of leaving 50% of the orebody as pillars and of finally extracting 50% of the pillars so left, the consolidated property should, beginning at the end of the year 1919 and for 16 years thereafter, be able to mill 1,750,000 tons annually at an average profit of 75c. per ton."

The Combination shaft, formerly the Mexican No. 2 shaft, now enlarged to five compartments, is being sunk, and is now down about 2100 ft. Mr. Bradley advises that this shaft be completed to the 3600-ft. level and be equipped with a new electric hoist capable of hoisting 5000 tons per day from the 4200-ft. level. He suggests that the Combination shaft should be equipped with twice the pumping capacity of the pumps at present in the Treadwell shaft, the latter to be held in reserve. The Combination and Central shafts should have all connections with the old workings closed by means of bulkheads. The Combination shaft would then become a down-cast and the Central shaft an up-cast for all future ventilation.

Diamond-drill holes sunk to a depth of over 500 ft. below the 2300-ft. level indicate the continuance of ore to that depth at least.

Flotation at Cripple Creek

The Vindicator Consolidated Gold Mining Co. has in successful operation a 300-ton flotation test-plant, employing the M. S. apparatus, treating mine and dump ore. The report for 1916 gives the following results from December 1 to the middle of January:

Heading, per ton	\$1.985
Tailing, per ton	\$0.410
Recovery, per cent	81.20
Concentrate, per ton	\$19.34
From January 1 to 9 results were:	
Heading, per ton	\$2.26
Tailing, per ton	\$1.38
Recovery, per cent.....	84.40
Concentrate, per ton.....	\$20.66
From January 9 to 15, on crude ore:	
Heading, per ton	\$5.40
Tailing, per ton	\$0.375
Recovery, per cent.....	93.10
Concentrate, per ton.....	\$40.25

The general manager, Irving T. Snyder, considers that these results are satisfactory, and the enlargement of the plant will follow during 1917.

Wilhelm Merton

In the recent death of Wilhelm Merton, founder and chairman of directors of the Metallgesellschaft of Frankfort-on-Main, Germany lost one of its foremost manufacturers and financiers. With his father, Ralph Merton, Wilhelm became a partner, early in the seventies, in the Frankfort metal firm of Philipp Abraham Cohen, which was converted in 1881 into a limited liability company called the Metallgesellschaft, with a capital of £100,000, afterward raised to £1,000,000. This organization with its subsidiary and allied companies, the Metallbank, the American, Australian, and African Metal Companies, and various Swiss, French, and Spanish enterprises has controlled a large part of the metal resources of the world. The War has lopped off some of its limbs, but in 1913 it was estimated that, apart from the private fortunes of the capitalists at the back of the organization, the capital invested in the concern was not less than £10,000,000. The English business of the Mertons was done through the firm of Henry R. Merton & Co., Ltd., of London. Last year the proprietary interests of this firm and the Frankfort enterprise were entirely severed by an exchange of shares, and the London Company now is wholly British-owned. Wilhelm Merton had been engaged on war work for the last two years, and it is stated that he co-operated actively in the drafting of numerous regulations dealing with the economic management of the War, and that "his advice caused many mistakes to be avoided," although his name was never publicly mentioned in connection with his work. In fact, the practice of self-effacement appears to have been one of his most striking characteristics, and in business circles he was very little known except as the head of three great metal firms, the Metallgesell-

schaft, the Metallurgische Gesellschaft, and the Gesellschaft für Metallwerte of Bale. He was also a director of the Frankfurter bank and of the German Gold-Silver Assaying Company.—*The Daily Metal Reporter.*

Alaska Gold

In April, 1915, Alaska Gold sold at 40½. The convertible bonds, of which there are two issues of \$1,500,000 each, sold up to 160. In January the stock declined to a new low point of 8½, while the bonds are down to 80.

No unusual developments have transpired at the property, beyond those which are currently set forth in the monthly statements. Combining these reports for the year 1916, we find that Alaska Gold treated 1,888,869 tons of ore which had a gross value of \$1.23 per ton. Deducting losses in the mill tailings of 22 cents per ton, there is found to have been \$1.01 per ton net recovery for the year. This compares with 93 cents per ton in 1915.

Reducing these figures to a theoretical income account, we have the following for the 12 months of 1916:

Net gold recovered	\$1,907,757
Estimated cost (71 cents per ton, as in 1915).....	1,341,096
Net profit	566,661
6% interest on \$3,000,000 bonds.....	180,000
Surplus	381,661

Of course it will be seen at once that after such development expenditures as have not been charged into current account, there is a very small balance left for the 750,000 shares of stock. In this connection it may be mentioned that in the year 1915 the so-called "deferred charges to operations" amounted to \$338,039. A similar expenditure for development this year would reduce surplus earnings close to the vanishing-point.

Alaska Gold represents in cost of property and development an expenditure of close to \$11,000,000. At \$40 per share the property had a selling-value of over \$30,000,000. Today it is selling for \$9,000,000, or \$2,000,000 less than has been invested in it.

The promoters firmly believed from experimental mill-runs and drill-hole assays that the ore would run not less than \$1.75 per ton, or \$1.50 after losses in mill treatment. Actual results to date show a net return of \$1 and this difference of 50 cents a ton, small as it may seem, spells either the success or failure of the whole enterprise.—*Boston News Bureau.*

IRON MONEY (small coins) is now used in Germany and Austria. The problem of protecting the pieces from rust was solved by super-imposing a thin layer of zinc. The discs of metal, together with some zinc-dust, are heated at a temperature somewhat below that of the melting-point of zinc (433°). The resulting surface not only preserves the coins from rust, but also enables the die to be impressed without cracking the surface of the metal. This zinc-plated iron money differs little in appearance or weight from nickel coins.

Dry Placer Mining

By A. Maltman

To the Plomosa mines, 26 miles south of Bouse, Yuma county, Arizona, is due the credit of installing and operating a successful dry-placer plant on a large scale.

The ground is cemented conglomerate, 25 to 30 ft. deep. Although the main deposit lies on and near the bedrock, the whole mass carries gold from the surface down. It will average \$1 per cubic yard.

The reduction plant is 75 ft. above the ground to be worked. It consists of one Sauerman Bros. drag-line excavator, the bucket having a capacity of $1\frac{1}{2}$ cu. yd.; it is operated by one man and will dig and deliver 50 cu. yd. per hour. The power is supplied by a 125-hp. Bessemer oil-engine. This engine consumes 10 gal. of 24° fuel-oil per hour at a cost of 7c. per gal. at the mine.

The contents of the drag-line bucket are dumped into a bin 12 by 12 ft. Immediately beneath this bin is a reciprocating feeder that has an opening of 24 inches, and receives everything that comes along; care, however, is taken not to allow any boulders to enter. From this feeder, the material drops into a Williams chain-hammer mill, consisting of a cylinder about 48 in. diam. and 6 ft. long. The cylinder is provided with hard-steel gratings set $\frac{3}{16}$ in. apart to allow the pulp to drop through. This cylinder moves at 30 r.p.m.; in the centre of it, extending two feet beyond either end, there is a shaft 5 in. diam., to which is attached a number of hammers fastened by a chain of three links on a collar. This shaft revolves at the rate of 400 r.p.m. The material to be treated does not need to be crushed but disintegrated and separated from the gravel. At the opposite end an opening allows the waste to discharge. About 40% of the whole mass passes out of this end partly broken up. The remainder, which contains the gold, passes through the grating and gravitates to an elevator having a capacity of 50 tons per hour. This elevator delivers the pulp to a No. 12 Stebbins dry concentrator that rejects 80% of the pulp. The remaining 20% is conveyed to a small elevator and enters a No. 7 Stebbins concentrator, which produces a finished product of gold, lead, and iron. In order to still obtain a further separation, the concentrate is fed to a No. $4\frac{1}{2}$ concentrator, which gives a final and clean product.

In the centre of the mill-building there is a belt-conveyor, 20 in. wide and 75 ft. long. This conveyor is so situated as to permit all of the waste material from the mill to drop on it and remove it out-doors. The three concentrators, belt-conveyor, elevators, and shaftings are driven by separate power, consisting of a 25-hp. International gas-engine, using distillate.

Several hundred feet from the tailing-pile, and on an elevation, there is another of the Sauerman drag-line dredging outfits operated by a 60-hp. Bessemer engine, which drags the tailing away to vacant ground. This is also run by one man, at the rate of 50 cu. yd. per hour.

The total cost of the whole operation is 15c. per yard. The plant was designed and built by the writer.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

OLD STEAM-BOILERS may be used as compressed-air receivers.

GOPHER BLASTING has been almost stopped at the Chino copper mine.

COARSE-ORE GRIZZLIES at Hurley, New Mexico, have openings 12 by 13 inches.

A 100-TON STEAM-SHOVEL, handling 2800 cu. yd. of overburden or copper ore in 10 hours, uses $7\frac{1}{2}$ tons of coal.

LIME AND SODA-ASH solutions are good precipitants of salts in water used in boilers, and act as water-softeners at the same time.

GOLD-CONTENT of the Chino copper ore is low, and in assaying, four assay-tons is reduced to get a bead of convenient size for weighing.

HYGIENE is defined as the science of health and of its preservation; the science, study, and knowledge of the means of keeping well and in good health.

CYANIDE TANKS made from corrugated galvanized-iron sheets have been successfully used. They are inexpensively and easily built, but they are much inferior to red-wood.

GASOLINE is used by army surgeons in Europe for the first cleansing of wounds on soldiers. The 'gas' does not cause any special smarting, yet care must be exercised in its use.

AN ALLOY is the fusion of two or more metals into a compound. Two or more metals may form a mixture and still not be an alloy, if one metal is but mechanically held between the particles of the other.

HIGH-SPEED machinery requires bearings of the best quality. The bearing-metal must have a low coefficient of friction and must resist tendency to rise in temperature to a destructive point when under heavy service.

THE parcel-post has recently been utilized to make shipments of high-grade ores where other methods of transportation were unsatisfactory. It is well for shippers to know that this can be done at a reasonable price.

CHURN-DRILL SAMPLING errors are as follows: deviation of the hole from the vertical; breaking off at the point of drilling of a surplus of rich brittle material, thus giving a sample that is too rich; concentration of heavy minerals in the bottom of the hole, so that they are not reached by the bailer, or are recovered from the hole

when it has reached a much lower depth where the rock may actually be barren; and caving of the rock from the sides of the hole.

THE NEVADA STATUTE requires that within 20 days from the date of location of a mining claim the boundaries of the claim must be defined by the placing of posts or monuments of stone at each of the four corners and at the centres of the side-lines of the claim. Ninety days are allowed within which to complete the location work.

EQUIPMENT for a charging (blasting) crew at an open-cut mine is as follows: springing-gauge, charging-sticks, pocket reflecting-glass, galvanometer, rheostat, blasting-battery, explosives, fuse, electric detonators, combination detonator-crimper, pliers, and punch, wooden mallet, large funnel, pocket-knife, wooden axe-handle, detonators, battery lead-wire, connecting wire.

LONG EXPERIENCE has demonstrated that broken rock passes most readily, without jamming, through raises (or winzes) when these cuttings have been made at an angle of about 50° with the horizon. When much steeper or flatter than this the rock is almost certain to jam, should the passage ever become filled completely and drawing off of rock be stopped for some time.

BABBITT, the accepted trade term for bearing-metal, is derived from Isaac Babbitt, Taunton, Mass., the first person of record to use a white-metal alloy as a lining for machinery bearings. In 1839 Babbitt conceived the idea of using an alloy made up of 4 parts copper, 24 parts tin, and 8 parts antimony. This was so successful that a gold medal and \$20,000 was awarded him by Congress in recognition of his service to American industries. Prior to that time brass or bronze bearings were used.

THE FLASH-TEST for oil is determined by placing a quantity of the oil to be tested in a shallow dish and setting a Bunsen burner beneath it. The bulb of a thermometer of a special make is then immersed in the oil and a lighted candle passed around the edge of the dish. When a flash follows the ignition of the vapor rising from the heated oil, the temperature of the oil is observed—the 'flashing-point' of the oil. If the heat is raised to a higher point the oil is likely to burst into a blaze. This latter is the fire-test.

NOTWITHSTANDING the fact that large numbers of new men have been engaged, and that 21 men were killed in its Pennsylvania mine, the Anaconda company reports a 23% reduction in accidents at its Butte mines during the first half of 1916. The principal reason for this reduction is that the company's Bureau of Safety has had the heartiest co-operation of foremen and shift-bosses, and that through their efforts the men are becoming educated to take care of themselves—to do things the safest instead of the easiest way. Many of the worst offenders in breaking rules are old-timers.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

SUTTER CREEK, CALIFORNIA

SAFETY ASSOCIATION FORMED.—CENTRAL EUREKA, OLD EUREKA, BUNKER HILL, AND KEYSTONE MINES.

At the suggestion of Edwin Higgins, formerly Chief Mine Inspector of California, a meeting of mine managers has been held at Sutter Creek, at which plans were made for perfecting the organization of the Mother Lode Mine Safety Association. Mr. Higgins has been conducting a safety campaign in this region for some time, and has offered various suggestions, which the mine-owners are adopting as far as practicable. The application of safety work was discussed at the recent meeting, also the general needs of the mining community, such as adequate hospital service, better housing of miners, as well as first-aid and mine-rescue training. Some attention was also given to the advisability of having public safety meetings, to include music, addresses, and moving pictures. Another meeting will soon be held to complete the organization, after which monthly meetings will be held. Foremen and others in authority at the mines are taking an active interest in this movement, and it is thought that these meetings will do much to promote co-operation between the various companies in matters pertaining to safety and efficiency.

At the Central Eureka mine, the 2500-ft. cross-cut, driven for filling, has cut some good-looking ore within the past week. The orebody appears strong. The shaft station has been completed at the 3250-ft. level, and driving is progressing well on the ore found in sinking.

At the Old Eureka mine it has been found that the size of the shaft below the 1600-ft. level is less than that so far re-timbered, there being but one compartment from that level down, so that the time required for unwatering will be less than was anticipated. Some difficulty is experienced in keeping the shaft crews employed near the various levels supplied with timbers, as there is only one small skip in use, but this difficulty will be overcome when the new engine and head-frame can be put into service. Ore-bins are being built on the new frame, and it is understood that the electric motors will be delivered within a few days. Contracts have been let for erecting the large platform from the engine-room to the new head-frame, over the shaft, and the space beneath will later be filled in by means of the waste to be hoisted by the newly installed equipment. Another mining carnival, similar to the Eureka carnival held here last year at the time of the sale of this old mine, but far more elaborate, is to be held here about April 1.

During the past week the Bunker Hill Consolidated Mining Co. has made public an interesting statement concerning the operation of its property at Amador City for the six months ending December 31, 1916. During that period the 40-stamp mill was operated 127 days, crushing 27,370 tons of ore, averaging \$4.014 per ton, excluding returns from tailing treated by another company. The net cash value of bullion produced was \$33,641; concentrate, \$77,225; while there was derived from tailing, interest, and rental of property the sum of \$2776. The actual cost of mining, milling, insurance, taxes, salaries, and general expense averaged \$3.722 per ton of ore treated. Mining cost \$81,472 and milling \$8577. The company spent on construction an additional \$24,237. This included 225 ft. of concreting in the shaft to replace the heavy timbers heretofore used just below the collar, the erection of concrete

ore-bins on the surface, and a large addition to the mill, as well as the building of a new road. The company discontinued its dividends in September, partly as a result of the strike, \$15,000 (half the usual semi-annual amount) having been disbursed in dividends since July 1, 1916. The surplus in the treasury has been reduced from \$43,358, six months ago, to \$15,867 on January 1, 1917. The mine is now well equipped for economical work, and after the shaft has been sunk to the proposed depth of 3000 ft. and levels opened, it is confidently expected that the Bunker Hill will exceed its record, which now shows 123 consecutive monthly dividends paid its shareholders prior to the end of last September. E. Hampton is superintendent and R. Christiansen, foreman.

The semi-annual report of the Keystone Mines, to January 1, 1917, shows a total of 21,260 tons of ore milled during the period. Forty stamps were in steady operation, that is, from July 1 to December 28, and from December 28 to the end of the year. During these times the bullion recovered was worth \$10,235; 771 tons of concentrate returned \$48,437, while \$499 was derived from the sale of base bullion. Freight and smelter charges were \$9257, reducing the net realization to \$49,915, or an average of \$2.34 per ton of ore milled. The company's disbursements are segregated as follows: mine account, \$74,000; corporation and license tax, \$117; interest on money borrowed, \$1017; secretary's office, including manager's salary, etc., \$1654. The present indebtedness of the company for money borrowed is \$20,423. In the past six months the shaft has been re-timbered from surface to the 400-ft. level, 80 full sets of 18 by 18-in. timber having been put in place. In repairing the 15-in. air pipe-line, 433 ft. of new pipe was used. Two new 3-ton skips have been put into service, and necessary repairs made to the hoist-drums, so that the entire plant is now in good physical condition. Work of extracting ore is in progress on the 900, 1000, 1200, and 1400-ft. levels. At 1800 ft. the station is nearly completed, and the face of the cross-cut is now 150 ft. from the shaft. Large reserves of low-grade ore are blocked-out on the four levels from which ore is now being taken, and the ore-bins now hold about 1104 tons. C. R. Downs of Sutter Creek is manager, C. L. Culbert of Jackson, secretary, and B. I. Hoxsie, foreman.

Publicity by Amador county companies is increasing.

DEADWOOD, SOUTH DAKOTA

REVIEW OF RECENT DEVELOPMENTS IN THE BLACK HILLS.

Higher prices for silver have stimulated prospecting for ores of that metal, and some of the old producers have been examined. The Shamrock, on West Strawberry gulch, near the Puritan, has lately yielded samples assaying as high as 118 oz. silver from a small seam. The owners intend to continue development, for this and similar stringers, together with a considerable quantity of lower-grade material, are believed to form the basis for milling operations.

Development planned for the Minnesota will consist of exploration of the Unionville vein, in the western part of the property. This outcrop has yielded consistently good assays, but has never been more than casually developed. An adit has been driven to intersect it, but has not yet penetrated the ore. It is now proposed to do work in this adit which has long been planned, but which has been deferred for various reasons.

At the annual meeting of the Deadwood-Heidelberg Mining

Co. the following directors were elected: H. S. Vincent, John Treber, A. T. Roos, Banks Stewart, I. Salinsky, Grant Ourth, and Jacob Goldberg. Superintendent Roos reported that work was progressing uninterruptedly on a connection with the surface, whereby it would be possible to expedite operations and cheapen the mining of ore from the west vein. This connection will also serve to ventilate the long cross-cut. As soon as it is made it is proposed to commence shipments of cyaniding ore to the Golden Reward mill, at Deadwood. Developments during the year were stated to have been satisfactory and encouraging.

The American Mining Corporation is the name of the new concern, backed by Iowa and Chicago capital, that has taken over the Alder Creek property and the Bismarck mill, at Flat-iron. Under the management of F. C. Bowman the mill has been overhauled and put in commission, at part capacity.

St. Louis backers of the Hill City Tungsten Production Co. are endeavoring to liquidate the indebtedness and put the operations on a substantial footing. Money has lately been received at the Hill City office to take care of a good portion of the debts, and enough more is promised to pay off the balance and leave a good working surplus. A complete change of management has been effected at Hill City. The mill is working at part capacity on tin ore.

Tungsten production of the Black Hills for 1916 came almost entirely from the Homestake and Wasp No. 2, both of which companies erected and operated 20 to 25-ton plants for concentration of the ore. Some small shipments were made from Hill City and Spokane, and discoveries that promise well were made at several points. One of the most important of the discoveries was made in Harney canyon, 4 miles south of Hill City, where a large pegmatite dike, said to average 1.25% tungstic oxide over a wide face, was found and located by W. L. Faust and others. Noteworthy finds were made in the vicinity of Deadwood, where replacement deposits in the Cambrian, similar to the productive deposits in the Homestake and Wasp No. 2, were uncovered, one of them, on Two Bit gulch, yielding some especially fine ore.

TORONTO, ONTARIO

PORCUPINE AND KIRKLAND LAKE.—TWO NEW GOLDFIELDS.—ELECTRIC-STEEL PLANT.

The quarterly report of the McIntyre mines of Porcupine for the last three months of 1916 was most encouraging. The gross production was \$356,504, and profits \$208,990 against \$136,083 for the previous quarter. There was 39,369 tons of ore treated, averaging \$10.62 per ton. Operating costs were reduced to \$4.51 per ton. Driving has been done for 670 ft. on the 1000-ft. level in McIntyre and McIntyre Extension ground, over 550 ft. being in high-grade ore. Stopping operations in progress show from 8 to 40 ft. wide of ore assaying \$15 per ton.—At the Davidson the main vein on the 300-ft. level is reported to have widened to 97 ft., which would make it the widest vein at depth in the Porcupine district, excepting that at the Dome.—The Boston owners of the Premier, better known as the Standard, situated south of Dome lake, have installed a new electric-driven plant, and opened a good orebody on the 100-ft. level. The shaft will be sunk to the 300-ft. level, and cross-cutting done to find this vein. A recent discovery on the 200-ft. level from No. 4 shaft of the Schumacher is developing into an important shoot 9 ft. in width. The West Dome is driving on the 300-ft. level. The vein is 5 ft. wide, and is worth \$12 per ton. On the dump, ore is valued at \$50,000 and arrangements are under way to have it treated.

At the Lake Shore, Kirkland Lake, development is progressing on the 300-ft. level, where a wide vein carries \$18 to \$20 gold per ton. The ore opened above this level is estimated to be worth \$300,000. An issue of 20,000 treasury shares has been made at 50c. each. Arrangements have been completed

for the construction of a mill.—The main vein of La Belle Kirkland has been cut by diamond-drilling at a vertical depth of 650 ft., showing 8 ft. of good milling ore. Two strong parallel veins of less width have been discovered.—The Hurd claims, south of the Tough Oakes, are being worked by La Rose Consolidated of Cobalt, and are developing well.

The new goldfield of West Shining Tree, 20 miles north-east of Kashbaw, a point on the Canadian Northern railway, 80 miles north-west of Sudbury, is attracting some attention. It would have received greater notice had it not been badly handicapped by inadequate transportation. Little development has been done so far, but several syndicates representing New York and Montreal capital are preparing to operate extensively. Of 56 properties, 52 show free gold. The veins vary from a few inches to 15 ft. in width, and from 50 to 2000 ft. in length, generally with good gold-content in the wall-rock.—Another new field that has recently attracted many prospectors is Powell township, situated north-west of Elk lake, and a considerable distance from any other field. The first discovery was made in November, and since then 75 claims have been staked.

Owing to the great demand for high-grade steel for shells, the Imperial Munitions Board is erecting large steel works at Toronto. Sixty acres was obtained on the water-front. The plant may be ready for operation early in July. Equipment comprises ten 6-ton, 3-phase, 25-cycle Heroult-type electric-furnaces requiring 20,000 hp., supplied by the Provincial Hydro-Electric Commission. The plant will not treat crude ore, but will use scrap metal, which is available in large quantities, and from which the best kind of steel is produced. It is expected that when in full operation the output will be 600,000 lb. of steel daily, and from 800 to 1000 men will be employed.

JOHANNESBURG, TRANSVAAL

GOVERNMENT LEASES IN THE FAR EAST RAND.—DOUBTFUL DEVELOPMENT WORK.—NEW METHOD OF SLIME-TREATMENT.

The Government has accepted the tender of the Brakpan Mines, Ltd., for the Brakpan area, and that of the Central Mining & Investment Corporation for the Modderfontein area adjoining the Rand Klipfontein and Cloverfield properties. In the case of Brakpan the area offered for lease amounted to 1811 claims, but the Brakpan company has not only offered the Government a 12½% participation in the working profits in addition to the 10% profit tax, but the property of the existing Brakpan Mines and that of Schapenrust is thrown in on the same terms. This means that, instead of receiving a 12½% participation on the 1811 claims offered for lease, the Government will receive 12½% on the results obtained from 3000 claims. The Government's participation seems to have been arranged so that 12½% of the profits will cover existing conditions, and any increased profits above the average to date, will increase the participation of the Government. For instance, so long as the ratio of net profit to recovery does not exceed 35%, the Government will be entitled to 12½% of the net profits; at 35%, 17.1%; at 40%, 21.3%; at 45%, 24.4%; and at 50%, 27%. If the yield is taken at 27s. (\$6.48) per ton, and profit at 9s. (\$2.16), this will mean a payment of 12½% of the profits plus 10% profits tax, a total of 22½% or, say, 2s. (24c.) per ton milled, payable to the Government. Another feature of the tender of the Brakpan Mines was the offer to pay 5% of the working profits earned by the Brakpan Mines during the first five years of the lease, in addition to the 10% profit tax. As the present profits of the Brakpan company are £300,000 a year, this means a payment of £15,000 a year plus profit tax during the first five years, during which period no ore can be expected to be extracted from the new area.

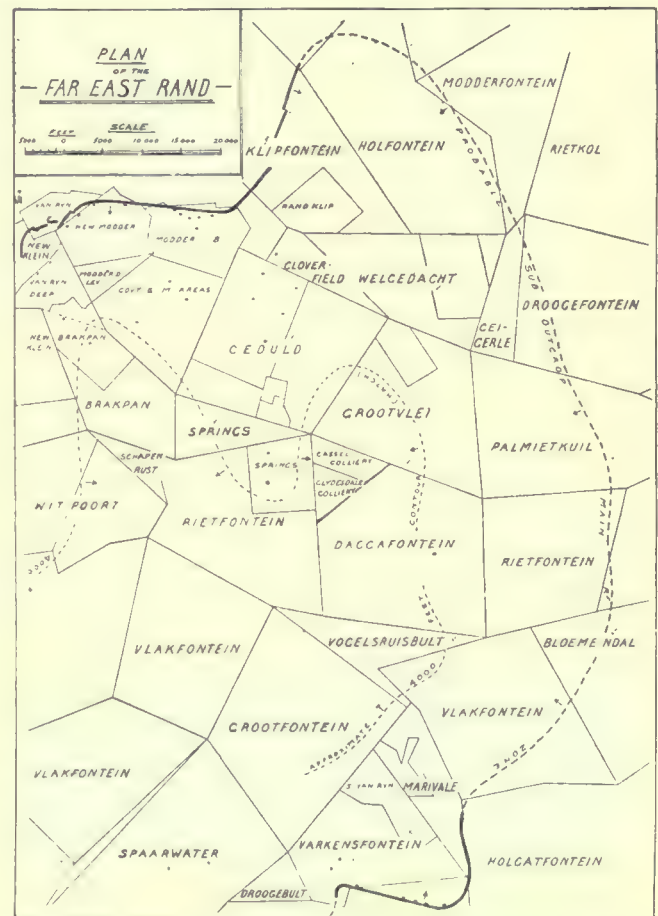

With regard to the Modderfontein area, the lease of which has been acquired by the Central Corporation, the terms are undoubtedly favorable to the Government. The amount pay-

able in this case is 10% of the working profits plus the usual 10% profits tax, or 20% in all. Then again the Government will gain considerably by the undertaking of the Central Corporation to form a company with a capital of £752,041, and absorb with the lease-area the properties of Rand Klipfontein and Cloverfield, over which the 20% will become payable to the Government. This means that, in addition to the payment to the Government of 20% of the profits earned on the 651 claims of the lease-area, the same payment will be made on the Rand Klipfontein and Cloverfield properties, amounting to 1799 claims, the 651 claims of the leased area being thus increased to 2450 claims. It is impossible to make any reliable estimate in this case of how much will be payable to the Government, as what little work has been done on the properties cannot be considered as very encouraging. In such a large area, however, as 2450 claims, it can confidently be expected that some profitable ore will be found. Bore-holes on the leased area showed an average value of \$5 over a stopping-width, and on the Rand Klipfontein 43,915 ft. of driving averaged \$4.60 over 21.7 in., while Cloverfield assayed \$16.60 over 11½ in. These are by no means brilliant results, and the Government must be congratulated upon being able to obtain such an excellent offer, for, had the 651 claims been reserved for a State mine, it is extremely doubtful whether the Government could have worked it at a profit.

The proposal to drive two cross-cuts from the bottom of the Angelo Deep shafts on the East Rand Proprietary Mines property to intersect at a distance of 2000 ft., and from the point of intersection to sink a prospecting shaft to the reef, has naturally given rise to much adverse criticism. It is difficult to see the wisdom of such a proposal, as the whole of the work will be done in country-rock, and the probabilities of finding a profitable orebody at the bottom of the shaft so small that such a huge expenditure as £200,000 appears quite unjustifiable. Already one of the directors has resigned in consequence of this proposal, and it will be fortunate if it does not lead to even worse happenings. Naturally, the best method of proving the dip area would be to continue the shafts on the incline of the reef, and should, at any time, a shoot of payable reef be found, arrangements can at once be made to work it to advantage. Then, by following the reef down from the two shafts and driving levels between the two inclined shafts wherever there is any necessity or inducement to do so seems by far the best step to pursue. It is admitted that these inclined shafts will have to be sunk eventually, but the truth is they have been too long neglected, and the foolish expenditure of £200,000 only makes the neglect more prominent. There are great odds against the prospecting shaft finding ore at a depth of 6000 ft. from the surface, but, by sinking on the reef, knowledge is gained all the time regarding the value of the reef, whereas, under the proposed scheme, £200,000 is expected to be spent before any knowledge of the value of the property at this particular point is obtained. It is, of course, possible that profitable areas may be found below the 27th level at the 4000-ft. horizon, where the value is only \$2 over a stopping width, but it is highly improbable, and, as a rule, the East Rand Proprietary Mines' property is locally regarded as a white elephant. During December 820 stamps crushed 153,000 tons of ore, which yielded \$900,000, of which \$180,000 was profit.

A new process of treating slime has been devised by the Mauss Continuous Centrifugal Separator, Limited. Only one machine has started so far, but, from what transpired at the third annual meeting of the shareholders at Johannesburg, there seems every prospect of success being attained in its treatment of slime. A trial was recently made at the Zaaipplaats tin mines, where the pulp fed into the machine was 45 parts of water to 1 of solid by volume, the recovery was 60% of the tin contained in the slime, compared with 25% previously obtained. The machine was first designed to treat slime at the near-by gold mines, but after the test at the Zaaipplaats tin

mine it is considered applicable to a variety of metallurgical and industrial purposes. E. J. Way, well known on the Rand for his experimental work, stated that no special arrangements were made at the Zaaipplaats mill for the feeding of slime to the Mauss machine. The current slime was turned direct into the machine and, although the best pulp for the machine was 9 : 1, the slime at Zaaipplaats consists of 45 : 1, nevertheless the results obtained were highly satisfactory. Mr. Way further stated that the product from the Mauss machine had been treated upon Frue vanners and an extraction of 60% metallic tin was obtained. Personally, he had found that Frue vanners were not the best machines to use for this purpose; he much preferred the Deister table, and had no doubt that with adjustments the recovery might be 75%. At the Rooiberg tin mine considerable attention had been paid to the treatment of current slime, and a special

plant for the purpose was erected, but the extraction was only 25%. At the Zaaipplaats, with the Mauss machine and Frue vanners, the concentrate gave from 50 to 55%. The power required to drive the machine is only 2½ hp., while the space it occupies is small. The Mauss machine consists of a drum 4-ft. diam., which, for treating tin slime, is made to revolve on a fixed axle at a speed of 500 r.p.m. Inside this drum are fixed two buckets or receivers revolving in the opposite direction at a speed of 100 r.p.m. The slime is fed into the large drum, which hurls the solid matter into the bucket or receiver revolving in the opposite direction to the drum, the motion of the buckets or receivers being so arranged as to present a clean face to receive the solids, which are delivered at a point arranged for. The water is dealt with by the drum on a similar principle to that of a cream separator, and so far no trouble has been experienced in operating the machine. It is claimed that vanners are too slow in their action to separate the various constituents of slime in a proper manner, but, by using centrifugal motion, perfect separation is obtained.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

ANCHORAGE. John M. Reid and the Mohawk Mining Co., of Anchorage, operating mines in the Willow Creek district, have given the Denver Quartz Mill & Crusher Co. orders for two quartz-mills and other equipment for free-milling ore. The machinery will be shipped from Colorado in time to make connections with the first boat leaving Seattle for Anchorage, usually the first week in April.

FORTY-MILE. The earliest placer mining in the Alaska part of the Yukon basin was done on the bars of Fortymile river in 1886, and during the next two years hundreds of miners came to the scene of the discovery. This event opened up inland Alaska and led to the discovery of the famous Klondike placers, on the Canadian side of the boundary, some 10 years later. Over \$200,000,000 worth of gold has been taken out of the Klondike and the Alaska Yukon placer districts in the 30 years since Forty-mile was discovered. Of this, \$6,500,000 of gold has come from the Fortymile district. This district is described in a report (Bulletin 375) published by the U. S. Geological Survey, entitled 'The Fortymile Quadrangle, Yukon-Tanana Region, Alaska,' by L. M. Prindle.

ARIZONA

AJO. The labor strike at the New Cornelia Copper Co.'s plant, which started on November 19—700 to 800 men going out, was officially declared off on January 19 by the Western

LEACHING-PLANT OF NEW CORNELIA COMPANY AT AJO, ARIZONA.

Federation of Miners, iron workers, carpenters, and electricians. The men are applying for their former jobs and the company is said to be showing no ill-feeling towards them. Construction of the new reduction and leaching-plant will now be continued. The company is erecting many modern and beautiful dwellings for its employees at Ajo.

CHLORIDE. A mill of 100-ton capacity is to be erected at the Elkhart mine. F. A. Wright and R. E. Whitcomb are largely interested.

The 1400-ft. level of the Tennessee mine is yielding over \$100 ore, according to samples from mine-cars.

The Chamber of Commerce has issued a 30-page booklet describing the Chloride mining district. A frontispiece is a panorama of the principal mines, which are briefly described. (Telegraphic Correspondence.)—Two cross-cuts 400 ft. apart have penetrated 11 to 14 ft. of ore in the north branch of the vein in the Gold Road mine. A third cross-cut is being driven on the level 200 ft. below the adit where the vein was first opened.

A machinist wiping oil from the pit beneath the large fly-wheel of the hoist at the Nellie mine last week accidentally caught the old overalls he was using for the work in the gears, resulting in smashing the wheel. The mine is shut-down until a new wheel can be cast and shipped to the property.

Within a few days the cross-cut from No. 2 shaft of the United Eastern will have been completed to the vein on the 665-ft. level. The company will install a small auxiliary hoist and resume sinking. The vein should be cut on its dip at about 950 ft. The mill is working satisfactorily.

The Big Jim shaft is now 585 ft. deep, and will be sunk to 620 ft. A station is to be cut at 600 ft., where a cross-cut will be driven to the vein.

The Tom Reed Gold Mines Co. employs a 5-ton auto-truck to transport ore to its mill from the Aztec shaft, distant one mile. A vein of good milling ore 17 ft. wide has been opened at the Gold Ore mine. The company will build a mill soon.

Oatman, January 30.

ARKANSAS

FORT SMITH. To connect this place, at which are zinc smelters, with the zinc districts of northern Arkansas, it is proposed to construct a railway. The Business Men's Club has the matter in hand.

CALIFORNIA

A new geological map of the State of California has just been published by the State Mining Bureau, at the Ferry Building, San Francisco. The geological formations found in this state are shown in 23 colors and symbols. The new map is 50 by 60 in., on a scale of 12 miles to one inch, and represents over two years of painstaking compilation from all available published reports and maps, both Government and private, as well as much previously unpublished data, both official and personal. An entirely new base map of the State was drawn for the purpose, and is strictly up-to-date as regards county boundaries, post-offices, railroads, highways, roads, power transmission-lines, oil pipe-lines, aqueducts, etc. In fact, it contains much more detail of this nature than is ordinarily placed on a geological map. The map is a fine example of draughtsmanship and of the engraver's art. The geology is given in detail, consistent with the scale of the map, and is the resultant work of many years on the part of James Perrin Smith, the well-known geologist. The map is available at \$2.50 per copy mounted on cloth with molding at top and bottom for wall-hanging, and \$1 per copy unmounted. These prices represent the cost of printing and distribution. This map is to be reviewed in the PRESS of an early issue.

GRASS VALLEY. The Kenosha mine is soon to be re-opened with Lloyd Root in charge. The main shaft will be sunk 800 ft. to 1200 ft. depth. A hoist and pumps have been ordered.

PLACERVILLE. Mining of chrome ore has added to the activity around this place, especially the work of the Manganese Co. of California, which is shipping ore.

COLORADO

BRECKENRIDGE. During the three months ended November 30 last the Tonopah Placers Co., operating three dredges in this district, made a net profit of \$64,405.

CRIPPLE CREEK. The report of the Vindicator Consolidated Gold Mining Co. for 1916 has been issued, and the remarks of the general manager, Irving T. Snyder, include the following:

Development totaled 22,029 ft., lessees doing 8294 ft. of this.

The quantity of ore added to reserves was somewhat disappointing, especially on No. 19 level of the Vindicator and No. 20 of the Golden Cycle shafts; but exploration at this depth is relatively little so far. Reserves are estimated at 412,796 tons. Profitable dump ores amount to 2,000,000 tons. Mining cost \$2.081 per ton.

The washing and concentrating mill, handling reject material from the Vindicator ore-house, milled 127,947 tons of \$1.68 ore at a cost of 17.4c. per ton. The flotation test-plant started work on October 25, treating rejects from the Golden Cycle ore-house, averaging \$2 per ton. Ball-mills of 300-ton capacity were installed, but only reduce from 150 to 200 tons. Changes may bring them to the designed output. Results show that the ore can be economically treated by flotation. The recovery is now 93.1%.

The year's output was 119,130 tons of shipping ore, worth \$19.27 per ton, of which lessees produced 61,152 tons. The profit was \$564,813, of which \$270,000 was paid to shareholders. The surplus is \$878,580.

LEADVILLE. More rich ore has been found in the Fortune mine in South Evans gulch. Eight feet of sulphide ore at a depth of 1000 ft. contains \$95 per ton in lead, copper, silver, and gold. Lessees opened this shoot. As water is expected soon, a motor-driven pump is to be installed.

The U. S. S. R. & E. Co. is now sinking its Jamie Lee shaft with three shifts.

SILVERTON. January ore shipments from this district will exceed those of this month for several years. More work is under way than for some time. Snow has not interfered with operations to any extent so far.

MISSOURI

JOPLIN. The zinc-ore market was \$4 per ton stronger last week. Most of the blende sold for above \$30 per ton. The average price in January was \$74.50. Production of the Missouri-Kansas-Oklahoma region was 8096 tons of blende, 176 tons of calamine, and 934 tons of lead, averaging \$79, \$49, and \$95 per ton, respectively. The total value was \$743,240.

From 1830 to 1916, inclusive, the Missouri-Kansas-Oklahoma region has produced zinc and lead worth \$328,471,258, of which \$34,961,993 was the output of 1916. From 1904 to 1914 the yield ranged from \$11,000,000 to \$18,000,000.

MONTANA

BUTTE. At the Great Falls electrolytic zinc plant of the Anaconda company 60% of the roasting, leaching, refining, and casting units are in operation.

The Lawrence mine of the Anaconda is to be closed for 60 days to allow of re-timbering the shaft. Cold weather is interfering with other mines being operated.

The Bullwhacker has doubled its daily shipments of 110 tons of ore, which averages 5% copper. Survey of a spur from the Northern Pacific line to this and eastern properties is finished. A leaching-plant is proposed.

On the 1000-ft. level of the Butte & Zenith stringers of 8% copper ore were cut last week. It is thought these indicate the proximity of the Specie vein. This mine is 6 miles west of Butte.

Pumps have been withdrawn from the Butte & London in the eastern part of Butte and the mine closed, but it is expected that development may be done through workings of the East Colusa mine.

In the U. S. Federal Court for Montana the Elm Orlu Mining Co. is to start suit against the Butte & Superior Mining Co., to restrain the latter from mining on 300 ft. or more of the Rainbow lode in the Black Rock claim of the B. & S. The Elm Orlu also demands an accounting for ore alleged to have been wrongfully extracted. This case is almost a continuation of the one decided in 1916.

During the last quarter of 1916 the North Butte company

earned \$808,072, of which \$322,500 was distributed in dividends. Development, which was satisfactory, totaled 6186 ft. At the Granite Mountain shaft the hoist is operating to a depth of 3600 ft. There was smelted 150,048 tons of ore and precipitate, yielding 6,729,561 lb. of copper, 289,854 oz. of silver, and 501 oz. of gold.

For the February meeting of the A. I. M. E. at New York, C. E. Nigham and R. S. Foster discuss the Pennsylvania mine fire of February 14, 1916, in which 21 men lost their lives on the 1200-ft. level. Immediately after the fire was discovered water was turned into the air-shaft until a suction-fan was installed at the surface of this shaft. When the fan was started there was a reversal of air-current, which was bene-

PLAN SHOWING WORK DONE TO PUT OUT FIRE IN PENNSYLVANIA MINE AT BUTTE.

ficial to those fighting the fire. The methods used were in general those in use at the Mountain View fire of 1913. Drifts and cross-cuts were driven from the nearest accessible workings to the fire, and as much as possible of it was extinguished with hose-lines and by pouring water into the workings above the sill and other inaccessible places by means of diamond-drill holes. The air-currents were controlled with bulkheads, doors, and brattices, so that the men would always be working with the air; that is, so that the smoke and gases would be carried away from them. As far as possible the air-pressure was maintained at a point where it was just sufficient to hold back the gases without supplying fresh air to the fire. All places were securely timbered and air and water-lines were kept in all faces. As many men as possible were employed in all the headings and frequent reliefs were given. The men worked 8-hr. shifts. Where the gases were too strong, helmet men were employed. The helmets used were Draeger, 1909 and 1911 models. In driving the headings great difficulties were encountered because of the gases and smoke, the heavy ground, and the water pouring down from the

diamond-drill holes. Wherever filling was met, spiling or forepoling was necessary, and in many places breast-boards were also required. On April 5, after many cross-cuts and drifts had been driven (see map), a quantity of burning timber fell behind the bulkhead across A 1250 at the junction with 1207. This was quickly extinguished and was the last fire actually seen.

NEVADA

(Special Correspondence.)—The Nevada Consolidated has been able to maintain a 75% capacity during January in spite of excessive cold and shortage of coal. This weather always reduces steam-shovel operations, it being difficult to keep their tracks open and water pipe-lines from freezing; frequently fires are kept burning along the small pipe-lines to the shovels. The worst of the coal shortage appears to be over. The shift trains to the smelter from Ely resumed regular schedule on the 23rd. The power-plant at McGill is using 20% of fuel-oil to assist the coal consumption; the oil costs more than slack coal. At the mines 75% of the ore coming from steam-shovel pits is primary ore. This ore is known to be profitable for several hundred feet below present levels.

The Consolidated Coppermines is treating a small quantity of ore in its 500-ton unit recently completed. It is not expected that much will be done on account of the weather and the coal situation for several months. The Morris shaft, which the company has been sinking slowly for several months, has a large flow of water that hinders operations.

The superintendent of the Ely Consolidated, W. Campbell, is pumping the water out of the Zack shaft. He expects to open the American shaft of the same company at once.

The Camp Bird company, which held a bond and lease on the old Ward mine, 18 miles south of Ely, has stopped work for good. The Denver people who held a lease on part of the ground are continuing work and are advertising for teams to haul ore.

H. C. McCullough, manager of the Argus Mining Co. at Taylor, has several teams hauling ore. He has stuck to this property for nearly 10 years, and deserves success.

The lessees on the Cuba lead mine, of Campbells, at Step-toe post-office, 20 miles north of Ely, have given it up. Several different parties have tried this, but all appear willing to quit.

Lessees on the old Vulcan mine, at Hunter, south-east of Cherry creek, continue to extract ore, but the roads and weather have interfered with shipments. The same conditions apply to several lessees operating at Hamilton.

There is little production of tungsten these days, owing to the market and weather.

During the past few days it has been warm, with thaws every day. If this continues the roads will soon dry and permit resumption of work on some of the outlying properties.

Ely, January 29.

GOLDFIELD. On the 750-ft. level of the Atlanta, 6 ft. of up to \$50 ore was opened last week. The ore shows large quantities of copper and silver. This ore will be treated by the Goldfield Consolidated flotation-plant. One hundred tons daily is to be extracted.

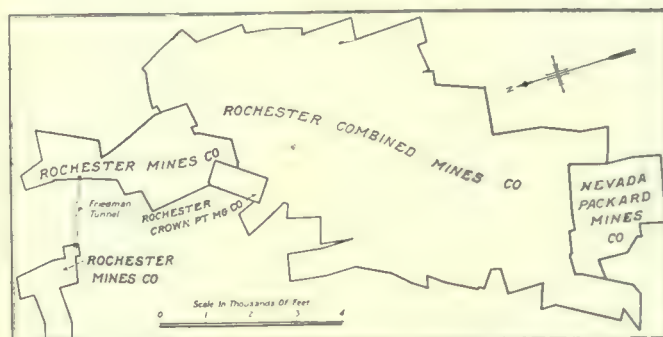

At a depth of 880 ft. the Jumbo Extension has opened a large shoot of gold-silver-copper ore, some of which assays \$40 per ton. Core-drilling continues at 1017 ft. depth.

Profit of the Goldfield Consolidated during December was \$16,441 from 26,000 tons of ore. Costs totaled \$4.59 per ton.

RAND. The Nevada Rand Mines Co. has recently been financed by Eastern capitalists. The work of sinking the shaft from the 250 to 450-ft. level commenced in December with one shift. The force will be doubled on February 1. This property has produced over \$30,000 in silver and gold.—Sinking the shaft below the 330-ft. level is in progress on the property of the Queen Regent property adjoining the Rand mine.—A new development of 4 ft. of ore carrying

over \$40 gold per ton has recently been made in the Gold Pen mine, which is also on the Rand fissure. The vein on the 260-ft. or bottom level of this mine is 26 ft. wide, 5 ft. of which assays \$19 per ton.—Three producing mines on the Rand fissure have produced \$150,000 in silver and gold.

ROCHESTER. In last week's issue mention was made of the consolidation of properties at Rochester, and the accompany-

PART OF ROCHESTER DISTRICT, NEVADA, SHOWING THE RECENT CONSOLIDATION OF PROPERTIES.

ing map shows the boundaries of the new company, and the other two principal operators.

The Rochester United, on Sunflower hill, has received settlement for 21 tons of ore assaying 2.23 oz. of gold and 4 oz. of silver per ton. Development is reported to be encouraging.

TONOPAH. During the quarter ended Nov. 30, the Tonopah Mining Co. had a net income of \$308,460, compared with \$122,712 in the previous period, although in the November term the profit from ore was \$179,117. Assets total \$1,593,812, including \$117,970 cash, \$1,019,831 bonds, and \$431,011 silver stored. A dividend on January 20 absorbed \$150,000.

The Belmont company expects to have its new mill at Surf Inlet, B. C., completed by July. Flotation is to be used.

NEW MEXICO

(Special Correspondence.)—During 1916 the Mogollon Mines Co., operating the Last Chance and Top mines, marketed 305,867 oz. of bullion, containing 5793 oz. of gold and 277,330 oz. of silver; also 93.8 tons of concentrate, containing 1378 oz. of gold and 94,020 oz. of silver. Development amounted to over 2200 ft., including 650 ft. of the new three-compartment shaft, which is now completed to 900 ft. This property has produced steadily for 15 years, and is one of the largest gold-silver mines in the south-west.

Development work on the Pacific mine has been confined to the 4th and 5th levels, as the present hoisting-plant is being worked to capacity. The new aerial tram is moving ore to the Socorro mill, one mile away. The cables run over regular standards to the edge of Silver creek, where one span of 2630 ft. connects it with the mill terminal. The buckets passing over the Maud S. mill travel 600 ft. above the creek. Each bucket carries 625 lb. of ore, 13 buckets are used, and 75 to 80 tons of ore can be moved to the mill in one shift.

The Oaks Company reports the following properties under operation during the week: Oaks drainage-tunnel, Harry, Johnson 19, McKinley tunnel, Clifton, and Eberle. The last two properties are shipping all ores taken out in development to the Socorro mill.

The cyanide shortage, which has been threatening to curtail mill operations, has been relieved, a fair supply having been secured.

Mogollon, January 23.

UTAH

Shortage of railroad cars is curtailing movement of ore in this State, especially at Alta and Tintic.

AMERICAN FORK. The coming season is to be the busiest on

record in this district. Electric power now being available makes power problems easier.

PARK CITY. After being enlarged the Broadwater mill is to resume shortly. The Big Four plant, closed on account of the weather, is also to re-start. When the new electrolytic plant of the Judge company starts it will have over 3000 tons of high-grade zinc concentrate to treat.

TINTIC. The 250,000-ton tailing-dump of the Mammoth, containing gold, silver, lead, and copper worth \$7 per ton, is to be sent to Utah smelters. Either the D. & R. G. or the Salt Lake Route will construct a spur to the dump.

WENDOVER. As the Ferber district is showing considerable activity it is planned to construct a branch from the new Deep Creek line in the spring. The mines of Ferber contain copper and lead-silver ores.

WASHINGTON

SEATTLE. The Bureau of Industrial Research of the University of Washington has issued a preliminary report on its investigation of the iron-ore resources of the Pacific Northwest. Active work on this investigation was begun in June 1916, by the appointment of A. S. R. Wilson, as geologist, and W. H. Whittier, as research fellow. Both of these men graduated in 1916 from the College of Mines of the University. The geological work done during the summer months last year consisted of an examination of iron-ore deposits at the following places: The magnetic black sand at the mouth of Sombria river on the west coast of Vancouver island; magnetite on Texada island; magnetite on the Kasaan peninsula, Prince of Wales Island, Alaska; and magnetite on Louise island, Queen Charlotte group. The geologic investigation has resulted in the determination that the magnetic sands as a source of iron ore in commercial quantity are not important enough to warrant further investigation, particularly in the light of the known occurrences of magnetic iron ore. It was also determined that magnetites occur over a wide range of territory tributary to the Pacific north-west and that further exploration is necessary before complete information dealing with exact resources will be available. In addition to the geological study of these deposits, samples amounting to over 2000 lb. were collected for further work at the laboratories of the university. These samples are now being analyzed for iron-content and impurities, and are being used in making mill-tests to determine the best methods of concentration and elimination of undesirable elements in the iron ore. This work is being completed as rapidly as possible so that information dealing with the character of the raw materials may be available soon. Economic questions dealing with the possible establishment and operation of an iron and steel plant in the North-west are being studied by Mr. Whittier. This investigation deals with the consumption of iron and steel products; the domestic and export market, especially the territory along the Pacific Coast; the influence of water transportation for the eastern region of this country and from China; the cost of raw material; the cost of production of iron and steel, and the market prices. The investigation will not be completed for some time.

The Bureau of Industrial Research is a result of a meeting which Henry Suzzalo, president of the University, had with a group of Seattle and Tacoma business men in which they offered to finance such an investigation.

KOREA

During December the Seoul company recovered bullion worth \$133,705. The net amount received during 1916 for copper sold at prices exceeding the basis used in monthly reports was \$150,000. Preliminary prospecting at Nau Churi shows interesting developments, and developments of the Tong Ahm property continues satisfactory.

The November clean-up of the Oriental Consolidated was \$135,865; December, \$164,239; 50c. dividend January 25.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

COURTENAY DE KALB is at Globe, Arizona.

COREY C. BRAYTON is visiting mines in Utah and Montana.

WALDEMAR LINDGREN is to be in South America for four months.

VICTOR C. ALDERSON now has his office at 185 Devonshire street, Boston.

E. W. CARSON is superintendent of the Oceanic quicksilver mine, California.

F. A. MALINS is mill superintendent for the Dos Estrellas company at El Oro, Mexico.

P. B. McDONALD has been appointed instructor in technical writing at the Toledo University, Toledo, Ohio.

G. B. BUTTERWORTH has been appointed manager of the South American Copper Syndicate's mines at Aroa, Venezuela.

D. C. BARD of Butte has joined the geological staff of the C. M. & St. P. railroad, and will have headquarters at Seattle.

HENRY P. SMITH and JOSEPH MACDONALD, JR., of the Guajato Reduction & Mines Co., Mexico, are inspecting flotation-plants in Nevada.

SAMUEL H. DOLBEAR, consulting mining engineer, announces the removal of his offices to Merchants National Bank building, San Francisco.

BRENT NEVILLE RICKARD, metallurgist, has been transferred from the Tacoma to the Murray plant of the American Smelting & Refining Company.

T. A. RICKARD delivered a course of five lectures on 'Technical Writing' during the past week to the engineering students in the University of California.

T. N. STANTON, late superintendent of mines for the Cananea Consolidated Copper Co., Cananea, Mexico, has returned to South America, and is superintendent of mines for the Cia. Estanifera de Llallagua, Llallagua, Bolivia.

OBAD A. PALMER, well known in Utah, died at Salt Lake City on January 13, at the age of 78. His work in the Park City and Tintic districts was of great value in subsequent development.

Belgian Relief Commission

The directors of the American Institute, on January 26, 1917, passed the following resolution unanimously:

In the name of all the members of the American Institute of Mining Engineers, this Board extends to Mr. Herbert C. Hoover, an honored Vice-President of the Institute, on the occasion of his present temporary return to his native land, the cordial welcome of his colleagues, and their congratulations upon the noble work splendidly done by the Commission for Relief in Belgium of which he is the head.

It is understood that a leading purpose of Mr. Hoover's visit to America at this time, is the collection of additional funds, to be administered by his Commission in the care of the destitute children of Belgium. To this enterprise endorsed by both belligerent parties, as well as inspired by the purest and tenderest sentiments of humanity, contributions are solicited from engineers, especially through an organization known as the 'Belgian Kiddies Limited,' which this Board, heartily approving its object and method, recommends to the consideration of the members of the Institute.

On motion duly seconded it was unanimously voted

That this minute be spread upon the record of the Board, and published in the Bulletin, and that a copy thereof be transmitted to Mr. Hoover, and to the San Francisco Section of the Institute.

THE METAL MARKET

METAL PRICES

San Francisco, February 6.

Antimony, cents per pound	24
Electrolytic copper, cents per pound	35
Pig lead, cents per pound	8.25—9.25
Platinum, soft and hard metal, per ounce	\$85—91
Quicksilver, per flask of 75 lb.	\$90
Spelter, cents per pound	12
Tin, cents per pound	48
Zinc-dust, cents per pound	18

ORE PRICES

San Francisco, February 6.

Antimony, 50% metal, per unit	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton	18.00—20.00
Magnesite, crude, per ton	8.00—10.00
Manganese, 50% (under 35% metal not desired)	16.00
Tungsten, 60% WO ₃ per unit	17.00—20.00

Tungsten appears in good demand with a slight advance in price from \$17.50 to \$20.

New York, January 31.

Antimony: High-grade ore is quoted at \$1.85 per unit.

Molybdenite: Further business for delivery within three months has been done at \$1.80 per lb. MoS₂ for high-grade concentrate.

Tungsten: About 300 tons has been placed under contract at prices close to \$17 per unit. It is reported that cold weather is interfering with production in the West, giving the market a stronger aspect.

EASTERN METAL MARKET

(By wire from New York.)

February 6.—There is no market for copper; prices are purely nominal. Lead is scarce with prices nominal. Spelter is quiet, and sellers are reserved.

COPPER

Prices of electrolytic in New York, in cents per pound.

The American Line has refused to take silver for transport to Europe because of the action of the German government in declaring gold and silver to be contraband of war. Although silver quotations are determined in London, the price-fixing is dependent on the figure at which the metal can be secured in New York, and eventually the buyers must pay the heavier insurance rates, as American bullion dealers will probably hold the silver for higher prices.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

ALUMINUM

Domestic consumption of aluminum in 1916 was over 121,000,000 lb., an increase of more than 21% over the consumption of 1915.

ANTIMONY

For Chinese and Japanese brands, 23. to 25c., duty paid, is quoted, prices having gone up sharply as a result of delayed deliveries from the West. It is admitted that a large quantity is in transit from Vancouver, but railroad conditions make the time of its arrival most uncertain. Considerable metal is in storage in this city, but the holders are unwilling to release it, for the reason that they must keep themselves in a position to meet their commitments of the next few weeks.

PLATINUM

Price of platinum, New York is \$100 per ounce for soft metal and \$106 for hard.

Eastern Metal Market

New York, January 31.

Copper is quiet, but nominal prices are fast getting back to high levels that prevailed in early December.

Zinc made a good start upward in the past week, but consumers did not support the rise, and the market is easier again.

Lead is the strongest of any of the metals—also the most difficult to find for prompt delivery. The A. S. & R. Co. has advanced its New York quotation to 8c., but the independents are asking up to 8.25c., and needy consumers would undoubtedly pay 9 cents.

Tin is higher because of a stronger London market.

A scarcity of supplies is sending antimony to high levels again, the prevailing quotation being 23 to 25 cents.

Aluminum also is stronger at 58 to 60 cents.

All the metals, and for that matter products of every description, are suffering from bad railroad conditions prevailing throughout the country, particularly in the West. At Eastern terminals, the freight congestion grows, while in the other parts, car shortages and bad weather conditions add to the trials of shippers. Traffic troubles have made the past week one of the quietest for some time in steel. Despite adverse conditions, the U. S. Steel Corporation in the last quarter of 1916 earned \$106,000,000, but the larger earnings are yet to come, as deliveries at the 2c. level have not yet been cleaned up. Foreign buyers, in their anxiety to obtain steel, are becoming less strict with regard to their specifications. All exports are restricted by the great difficulty of finding ocean freight-space. Prices remain firm in every direction in the iron and steel field. The metal-working machinery trade is quieter, and deliveries are becoming easier, especially where machines are not strictly high-grade.

COPPER

The copper market is practically back where it was prior to the break that followed the peace talk. Near-by and spot metal is practically unobtainable, despite the quantities which were pressed for sale, during the decline, by dealers, consumers and even some of the producers, all of which is evidence that faith in the situation is quite generally restored. Present quotations are nominal, inasmuch as there are few transactions to test the market. Strictly spot is quoted by some of the dealers as high as 35 to 36c. per lb., but more conservative factors put spot at 33 to 33.50c., February at 31.50 to 32.50c., March at 31.50 to 32c., and second quarter at 30 to 31c. Talk of a big order to be placed by the Allies for second-half delivery has subsided to a great extent. Just why copper is so scarce is explained only by conjecture. It has been maintained that the producers did not want to sell because of their expectancy of a big foreign order, also that they are short of metal and need all they have for the fulfilment of commitments. It is certain they are behind on deliveries. Severe weather in the West has impeded production, the railroad congestion has delayed deliveries of raw materials and finished products, while labor troubles at Eastern refineries have cut down production. It seems logical to suppose that the producers have none too much metal to satisfy demands they must meet. The big purchase by Great Britain, for instance—calling for 200,000 tons to be delivered in the first six months of 1917, at the rate of 75,000,000 lb. per month—has entered upon its period of delivery, but export statistics for January do not show that foreign shipments have been increased. Exports for the month, lacking one day, total 23,551 tons, which is under normal. All this argues for a strong market. Bearing out some of the foregoing, it is estimated that the January production was but 183,000,000

lb., against 210,000,000 lb. in December. For the first time in months the London market has shown an advance in the past week, the last price cabled for spot electrolytic being £143. The trade, however, attaches little importance to the advance in view of the fact that prices in Great Britain are officially controlled.

ZINC

In the past few days it has appeared that zinc was in for a steady and important move upward, but on Monday (January 29), when the New York quotation for prime Western ranged from 11 to 11.12½c. there came a slump which can only be credited to the rush to sell. Prices broke at least ½c. that day, and business became quiet. It was demonstrated that considerable spot and near-by zinc is in the East. Yesterday the New York quotation was about 10.75c. for spot and February, with March about 10.50c., and second quarter about 9.75c., the St. Louis prices ranging about ½c. lower. The conclusion to be drawn from the drop in prices is that the advance was abortive because of the lack of sufficient needy consumers to support it. An interesting phase of the situation according to a representative of one of the producers, is that Joplin ore—now quoted around \$90 per ton—is not fixing the price of zinc, but zinc is fixing the price of the ore. Brass-mill special commands a premium of 1 to 1½c. over prime Western. Exports in January, lacking one day, total 7555 tons. The London quotation for spot yesterday, the 30th, was £47, unchanged as compared with a week previous. Sheet zinc remains at 21c. per lb., f.o.b. mill, carload lots, 8% off for cash.

LEAD

In this metal most of the interest of the week has been centred. Freight conditions are holding up thousands of tons in transit from the West, and the result is a shortage which makes spot and near-by practically unobtainable, except for small lots, and even these are not easy to find. A few consumers have been obliged to close their works, and more are likely to shut down unless the situation is relieved—and no relief appears to be in sight. A dealer relates that a shipment which he hopes will reach him some time has been on the way since early November. Neither he nor the railroads know where it is. Incidentally the trade is wondering what will happen to prices when shipments do break through. On January 29 the A. S. & R. Co. announced its long expected advance, making its New York quotation 8c., but the announcement had little effect on the outside market, inasmuch as the new price is only used as a basis for compiling monthly averages. Those who have lead can get almost anything they want for it—some buyers would be glad to pay 9c. Sales were made within the past day or two at 8.10c., f.o.b. St. Louis, February shipment, and at 8.25c., New York. The London quotation is unchanged at £30 10s. for spot. Exports of the month, lacking one day, total 1290 tons.

TIN

Continued advances at London have carried the spot Straits price to £193 2s. 6d. (equivalent to 41.05c.), which was the quotation yesterday (January 30), compared with £189 on the 22nd. Some important London traders have been buying heavily of late. Deliveries into consumption in January established a new record, amounting to 7177 tons, the previous high figure having been 6398 tons last June. Of the January deliveries, 1977 tons came via Pacific ports. Business in New York has been light since the last report, but the strong London market caused prices to advance, today's quotation being 45.75c. In stock and landing at the end of January was 2622 tons, while there was afloat 3033 tons.

Silver in 1916

*Briefly the following factors affected the market during the past year:

Month	Average price per oz.		Factor
	New York, cents	London, pence	
January ...	56.775	26.960	{ General coinage demand for allied and neutral nations
February ..	56.755	26.975	
March	57.935	27.597	{ Indian Mint starts to buy
April	64.415	30.661	
May	74.269	35.476	{ Heavy shipments from China
June	65.024	31.060	
July	62.940	30.000	{ Great reduction in Indian Treasury silver reserves
August	66.083	31.497	
September .	68.515	32.584	{ Less competition from Allied Governments
October	67.855	32.360	
November ..	71.604	34.187	{ United States loan to China, part remitted in silver
December ..	75.765	36.410	
			{ Demand for U. S. Mint
			{ Some speculative activity for the rise
			{ Cessation of China sales
			{ Indian Mint a keen buyer

These prices were for cash delivery, there being no quotations for two months' delivery.

The year opened with fair prospects for silver. Coinage for Allied and neutral European nations was in operation, and a steady continuous pressure was being exerted upon the world's supplies in order to fill currency demands in England and abroad, which became keener as the year wore on. During the first 2½ months the price kept within ½d. (1½c.) of 26½d. (53½c.) The reluctance of prices to rise, notwithstanding the strength of the market, was attributable to sales of silver on account of China, where the visible accumulations of metal were large. The Indian Bazaars betrayed only an intermittent interest, not of an active character. Meanwhile a persistent decrease in the holding of silver rupees by the Indian Treasuries indicated that purchases would have to be made ere long for the Indian Mints. The War had imposed an unusual strain upon the stock of rupees. In three great theatres of the War—Mesopotamia, East Africa, and Egypt—these coins were in exceptional demand. In the last-named country the rupee was made legally current as a temporary expedient, until such time as sufficient piastres could be minted and put into circulation to meet the need of the troops. The large quantity of rupees that have obtained a fresh domicile, especially those in Mesopotamia, will not be quickly repatriated. Circulating among the Arabs and other denizens of countries bordering upon the Persian gulf, they have filtered into the interior, where silver currency, hitherto somewhat of a luxury, is welcome. An urgent demand for new currency in Australia, owing to the activity of war industries, led to an arrangement for silver yielded by Australian mines to be minted in the Commonwealth, so as to relieve the Royal Mint at London, fully occupied with British coinage. In the third week of March, a shipment of £350,000 was announced from China to India, and a sharp change came over the market. The stock of rupees in the Indian Treasury was 2806 lacs (1 lac = \$32,000) on December 31, 1915. By March 22, 1916, the total had fallen without a break to 2215 lacs; hence there was little doubt that the shipment was made on account of the Indian government. The price at once sought a new level, reaching 28½d. on March 24, and hovered in that neighborhood until the beginning of April, when a fresh upward movement began. Notwithstanding substantial purchases of silver in China, and

also in London, the drain of rupees from the Indian treasuries still continued until on December 22 the total was only 1623 lacs, a decrease of 1183 (\$37,856,000) in a year. The note circulation meanwhile increased from 6297 to 7963 lacs. During April, currency demand became increasingly active for the Continent as well as for the Indian and British mints. The last mentioned continued to find difficulty in coping with local needs. The healthy condition of the market encouraged speculative purchases on the part of the Indian Bazaars and elsewhere. The impetus generated by enquiries, so varied and constant, carried the price to 30d. within a fortnight, and to 31½d. within three weeks, and from this point until May the market developed remarkable strength. The highest quotation in 1916—37½d.—and the highest since 1893, was on May 3. It may be here observed that the great reduction in supplies from Mexico, where unrest has seriously hampered mining operations, especially in the northern districts, accentuated the difficulty of meeting the unusually urgent requirements that had arisen. Further, the undefined political situation in China prevented the trade of that country from acting as a counterpoise to silver in accordance with custom. High silver prices acting upon the China exchanges formerly had the effect of encouraging automatically foreign imports to a degree somewhat commensurate with the rise in rates, but internal conditions in China and the difficulty of shipping were not favorable to foreign imports. Therefore, the release of silver from China represented rather a transfer of capital than a transfer of trade. Hence the link between silver and the China exchanges failed to check the headlong course of the market. Some new sources of supply were tapped. Certain current coins, such as Mexican, Philippine, Maria Theresa dollars, etc., became worth more dead than alive. After a healthy reaction the price again mounted as high as 37d. on May 12. On the 15th, the total of silver—coined and uncoined—in the Indian reserves fell to 1771 lacs, the lowest figure recorded since January 24, 1914. This had much to do with the strong tendency of the silver market, for the currency figures are always closely watched by the Indian Bazaars. Not without reason, for they afford a reliable barometer—and a fall to 1800 lacs has been considered by authorities as danger-point. The reduction below the total hitherto considered advisable naturally encouraged speculative buyers, and the quotation kept at 36d. or over until May 20. An arrangement having been made to avoid unnecessary competition between mintage orders, the Indian Bazaars—at the time large speculative holders—took alarm, sold heavily, and by so doing, depressed the price instantly to 34d. on May 22. The decline continued, despite temporary rallies caused by spasmodic spells of speculation, until 28½d. was quoted on July 10. Throughout this period the Indian government, assisted by falling China exchanges, was able to replenish its reserves with such success that the Indian Bazaars, becoming obsessed with unfavorable views, not infrequently made bear sales in the London market. For the next 2½ months the inclination of prices was steadily upward. A loan by the United States to China reduced supplies from America to the open market, inasmuch as about 1,000,000 oz. was remitted in silver. On the other hand, China sold frequently either to the Indian Mint, the Bazaars, or London. Throughout October the price remained steady. Meanwhile the United States Mint absorbed some of the local supplies. The stock in Shanghai continued to shrink, and the China exchanges began to approximate the par of silver, suggesting that China had released about as much silver as could be spared, in view of the growing activity of its exports. Early in November the tables were turned. China ceased selling and commenced buying. The new factor

*Abstract from 'Annual Bullion Letter' of Samuel Montagu & Co., London.

was felt at once. The price rose rapidly, and after a slight reaction the advance was resumed until 36d. was recorded on December 2. The price remained about this figure for a few days and then again took an upward course, which carried it to 37d. on the 15th. This figure was attained the day after the Indian government announced that its allotments of Bills and T.T. would be confined to the amounts offered for tender. The main factor in these rising prices was the continuous and heavy withdrawal of rupees from the Indian Treasury. In the latter half of December a considerable quantity of silver—reported as over £1,000,000 in value—was acquired for the Indian Mint at Bombay and Calcutta. The pressure being somewhat relaxed, prices eased off toward the close of the year.

Appended will be found the apparent stocks of bar silver at

ment takes place, the more powerful the leverage will be upon the price of silver.

It is not surprising that the Indian Mint has figured as an extremely important buyer, for there has been not only external demand for silver rupees incidental to the War, but Indian crops have commanded unusually high prices. The Indian peasants, therefore, required correspondingly large payments in a unit commensurate to their daily needs.

Concerning the future of silver, present world conditions being unprecedented, and the course of events touching finance so uncertain, any forecast of future movements of the price would be guesswork. However, two factors can reasonably be anticipated to be an influence during the War, namely: a more or less persistent demand for silver currency as a consequence of the locking-up of gold and other causes, and a degree of

the close of 1916 as closely as can be ascertained, together with corresponding figures for the three preceding years, in ounces:

	1916	1915	1914	1913
Shanghai	not reported	720,000	500,000	2,660,000
Bombay	2,420,000	6,900,000	5,000,000	1,320,000
At sea	*1,400,000	3,125,000	1,500,000	2,000,000
London	6,350,000	6,800,000	11,000,000	15,800,000
Total	10,170,000	17,545,000	18,000,000	21,780,000

*Exclusive of silver consigned to the Indian government.

The totals of sycee (60-oz. shoe-shaped bars) at Shanghai for the four periods were 1916, 23,900,000 oz.; 1915, 62,100,000 oz.; 1914, 68,000,000 oz.; and 1913, 50,300,000 ounces.

Two circumstances are of interest in connection with the shipment of silver from China. First, that the demand for remittances to London was large and continuous, and evidently independent of the movement of trade. The likeliest solution is that foreigners in China have been transmitting unusually large amounts of capital from China to the United States and Europe. Second, China could not indefinitely dispense with the currency represented by these shipments of sycee and dollars that have taken place. The reflex influence of the operations referred to, must ultimately be felt by the future trade in China, inasmuch as the replacement of the exported currency, which may amount to one-quarter of the world's production for one year or even more, will influence considerably the price of silver and China exchange rates in sympathy. The shorter the period during which such replace-

stringency of supplies, owing to the great drain made on them during the past year.

DURING 1916 the New York & Honduras Rosario Mining Co., operating in Honduras, Central America, yielded an average of 150,600 oz. of silver and 1280 oz. of gold per month, from 10,565 tons of ore. The value averaged \$125,000. The December output was 11,600 tons for 182,000 oz. of silver, and 1550 oz. of gold, valued at \$165,000. In 1915 the average monthly yields were 9815 tons, 145,659 oz. of silver, and 1267 oz. of gold, valued at \$97,125. Silver in 1915 realized 50.1c. per oz.; in 1916, 66.6 cents.

The Calumet & Hecla company reports as follows for December and 1916, in pounds of copper:

Mine	December	1916	1915	1914
Ahmeek	2,321,536	24,142,158	21,800,492	13,634,605
Allouez	770,223	10,219,290	10,043,459	6,056,548
Calumet & Hecla.	6,424,053	76,762,240	72,613,320	53,691,562
Centennial	193,050	2,367,400	2,347,509	2,287,130
Isle Royale	1,113,814	12,412,111	9,342,106	6,601,235
La Salle	169,211	1,380,352	782,493	540,731
Osceola	1,561,836	19,586,501	19,731,472	14,970,737
Superior	254,477	3,034,656	3,866,484	3,217,635
Tamarack	582,267	6,618,507	3,888,150	1,074,808
White Pine.....	238,307	4,207,449	2,824,145
Total	13,628,774	160,730,664	147,239,621	102,074,992

Industrial Notes

Information supplied by the manufacturers.

A New Gable-Bottom Ore-Car

The Orenstein-Arthur Koppel Co. of Koppel, Pa., claims that its new car possesses every improvement known in gable-bottom iron-ore cars. The side-door locking-gear is of special interest as each door is held closed by a longitudinal shaft running along the bottom edge of the car underneath the door, the shaft being provided with manganese cast-steel hooks which engage the bottom of the door. This shaft has a hand lever at one end, and the lever is kept in position by means of a spring-catch. Previous designs for a door locking-gear provided for a longitudinal bar fastened to the door, the bar fitting into catches at each end of the car, but on account of the load pressure against the doors it was necessary to hammer the catches loose; the catches also became filled up with dirt and ice so much that it was difficult to unlock the door. The construction of this car does away with the defects mentioned thus effecting a considerable saving in time and repair expense. Manganese-steel wheels with caged roller bearings are used. Cars of this type are being used extensively for locomotive haulage in the Michigan and Minnesota iron-ore ranges on account of their rugged construction and ease of operation. Some thirty odd of these cars have lately been shipped to the Pickands Mather Co.'s properties in Minnesota.

The Largest Electric Motor

The accompanying illustration shows the largest electric motor ever constructed, namely, of 15,000 hp. It was made by the Westinghouse Electric & Mfg. Co. of East Pittsburgh, and

THE LARGEST ELECTRIC MOTOR.

is described as a reversing motor, designed for driving 35-in. reversing blooming mills in steel plants. The man standing by the machine is 6 ft. high, so further details of size would be superfluous.

Commercial Paragraphs

In catalogue No. 710, of 106 pages, the HARRISON SAFETY BOILER WORKS of Philadelphia describes and illustrates its open feed-water heaters, heaters and receivers, valve-stack heaters, and water-softener heaters.

The Union Zinc Co. at Knoxville, is enlarging its mill, and has just given the DENVER QUARTZ MILL & CRUSHER Co. a hurry-up order for a quartz mill. A. A. Blow is president of the company, which uses oil flotation in treatment.

In its new 55-page catalogue SAUERMAN BROS. of Chicago detail and show the use of their power-scraper. Stock sizes

range from $\frac{1}{4}$ to 2-cu. yd. capacity. Any power may be used. Sketches are given showing arrangements of scrapers in the field.

In Bulletin No. 250, the SPRAY ENGINEERING Co. of Boston, Mass., describes and illustrates in an informing manner its 'spraco' equipment for washing and cooling the ventilating air for steam turbine-driven generators. The spray-nozzles are shown in detail.

In the suits of the DEISTER CONCENTRATOR Co. v. the DEISTER MACHINE Co. in Indiana and Chicago the Machine company won. In the first case it was a question of the use of the name by the Machine company; in the second it was in regard to infringement of the Concentrator company's patents.

The JASPER QUARRY Co. of Sioux City, Iowa, is quarrying a bed of extremely hard dense quartzite that is used in grinding-mills requiring a refractory lining. The company says it has already been subjected to severe tests and that it has come up to every requirement. It has been placed on the market under the trade name of adamant-silica.

On January 3, 1917, at the Pittsburgh Athletic Association, occurred the annual convention and banquet of the sales representatives of the VANADIUM-ALLOYS STEEL Co., Pittsburg, Pa., which manufactures high-speed, carbon, and alloy tool-steel. Some interesting topics were thoroughly discussed, the most prominent being a paper on crucible tool-steel read by Roy C. McKenna, president of the company. This company has for free distribution a folder descriptive of 'vasco-marvel,' a semi high-speed steel. This folder contains much information of interest, together with the high-speed steel standard classification of extras adopted July 22, 1915. The company owns valuable tungsten properties near Boulder, Colorado.

Bulletin No. 70-A, second edition, of the SULLIVAN MACHINERY Co., describes the Sullivan rotator hammer-drills, classes DP-33 and DR-33. Standard rotators are made in five different styles, as illustrated and described in this bulletin. These include a drill with hollow piston, a drill with air-tube, one with tube for use with steam, and one with water-tube for cleaning the hole for use in driving. Two styles of mountings are described; the shell and cradle mounting with feed-screw, and the pneumatic-feed mounting. The DR-33 auger-type rotators for soft ground, are also fully described, and the bulletin contains a number of new illustrations showing the application of these practically 'all-around' hammer-drills to different classes of rock-drilling work.

The CHEMICAL ENGINEERING catalogue recently issued is another instance of the American tendency to do something in a better way than it has been done before, and to do it more cheaply, by doing it more scientifically. The catalogue is a standardized collection of the advertising matter of the various manufacturers of chemical engineering apparatus and supplies, and will eventually contain in a single volume practically all of the available information on raw materials, equipment, and supplies that previously has demanded the maintenance of an extensive file of manufacturers' catalogues and an elaborate filing system. This catalogue is a convenience and an economy to both producer and consumer, and since it is thoroughly indexed and cross-indexed, it serves the additional purpose of the ordinary trade directory.

HEATON'S ANNUAL, 1917. Commercial handbook of Canada. P. 518. Index. Heaton's Agency, 32 Church street, Toronto, Canada. Price, \$1.25.

With its usual promptness, this annual reference book on all matters pertaining to the Dominion of Canada, is now to hand. Several improvements and refinements are noticeable in this, the 13th number. Statistical data are official. Readers of the PRESS will naturally turn to the mining section and will find 16 pages devoted to the minerals of Canada. Generally speaking, Heaton's will be found worth a place on any book-shelf.

EDITORIAL

T. A. RICKARD, Editor

LAST year the group of disseminated-copper mines under the Jackling management produced nearly 25% of the American copper output, the aggregate being 220,500 tons, which was 31% more than the same group of mines produced in 1915. Assuming an average price of 25 cents per pound, the joint product was worth about \$110,000,000.

DURING the three days beginning on February 19 the American Institute of Mining Engineers will hold its annual meeting in New York City. We note that the occasion is to be used to hold a re-union of Harvard mining engineers and geologists on February 19. Such foregatherings of friends fulfill one of the chief purposes of the Institute meetings.

SHORTLY after this issue reaches our readers they will learn who has been elected President of the American Institute. We hope, whatever the result may be, that the candidate not elected will be nominated and elected without opposition for the following year. This is suggested in the best interests of the Institute and in the hope to avoid the recurrence of competitions not in keeping with the dignity or welfare of the profession.

FREIGHT-RATES across the Atlantic have become a vital factor in the foreign copper trade. Before the diplomatic break with Germany it cost \$75 per ton to transport copper to Mediterranean ports as against a \$4 rate just before the beginning of the War. Insurance was quoted at 10%. To French ports the freight-rate was \$45, as compared with \$2.50 or \$3 per ton in normal times. The British government has taken freightage to England into its own hands. At the present time traffic across the Atlantic is practically in abeyance.

IN our last issue a typographical error was made when comparing the output of gold in the Transvaal in 1916 and 1915. In 1916 it was 9,295,538 ounces, worth £39,484,934—the highest on record—and in 1915 it was 9,093,671 ounces, worth £38,627,461, so that the gain last year was £857,473 or \$4,158,875. The gain made by 1915 over 1914 was £2,970,000 or \$14,404,500. In 1916 the total of dividends declined further, being estimated at £7,300,000 as compared with £7,824,799 in the year preceding. These changes are due to the impoverishment of the older mines of the Rand without an adequate gain in output and profit from the younger enterprises. The best showing is made by the Modderfontein group, including the Government Areas, which doubled its milling plant during the year. The East Rand Proprietary

has never recovered from the fiasco of 1911 and went further down-hill during 1916. Subsidence underground, producing air-blasts, have continued to handicap the Village Main Reef. The Randfontein Central has improved its output notably, thanks to better management. On the whole, however, the story of the Rand in 1916 serves to remind us that the greatest of all gold-fields has passed its zenith.

IN December the sale of the Tyee copper smelter, at Ladysmith, on Vancouver island, was reported as having been sold to American capitalists for \$275,000. Various interests were credited with the transaction, notably the Guggenheims and the Consolidated Company at Trail. It appears now that the purchasers are a group that includes Mr. F. A. Sieberling, president of the Good-year Tire & Rubber Company. Additions and alterations to the plant are being made under the direction of Mr. W. J. Watson with a view to increasing its capacity to 1000 tons of ore per day, as compared with the former capacity of only 600 tons daily. It is understood that a supply of copper ore is to be derived from the Mount Sicker mines in British Columbia and also from sundry Alaskan copper mines, as well as from customers elsewhere on the Coast.

EXCESSIVE taxation has caused the Canadian Mining Corporation, controlling the Cobalt Town Site, Cobalt Lake, City of Cobalt, and other properties at Cobalt, Ontario, to change its registry from England to Canada. It is stated in a circular to the shareholders that the advantages to be gained by the transfer will be (1) an active share-market at New York and Toronto, as well as London, (2) economy of management, and (3) conversion into dollar shares. The real grievance is the double taxation, namely, the English income-tax on profits remitted to London and the Canadian taxes. There is also an idea of escaping any future liability on the excess-profit tax. In London the action of the corporation is deemed unpatriotic and the *Financial Times* suggests that the Treasury or the Stock Exchange committee may forbid dealings in the new Canadian shares until after the War.

STEPS are being taken by the Minerals Separation people to exact royalty from those not licensed by them to use the froth-flotation process. We publish a copy of the letter sent by their lawyer to various mining companies, together with the list of questions the latter are ordered to answer. The tone is mandatory and per-

emptory. Some of the questions are inquisitorial and unwarranted. It is no business of Minerals Separation what "type and manufacture of apparatus" is used by anybody. The Supreme Court has upheld the validity of patent No. 835,120, but defined it closely, and under that definition no embargo is placed on the use of any machine unless it involves the application of a process employing less than 1% of oil and the 'beating-in' of air. Again, the demand for particulars concerning "any flotation tests" made on the ore is quite outside reasonable curiosity—it is an impertinence. The object evidently is to obtain information for the use of Minerals Separation and to discover the names of metallurgists engaged in experimental work, in order to put them on a black list. Thus the company is continuing its maladroitness of antagonizing those engaged in mining and of creating an intensified opposition to its alleged monopoly. The Miami appeal has been heard before the higher court at Philadelphia and the suit of Minerals Separation against the Butte & Superior company comes to trial at Butte on March 19. New evidence will be presented by the defendant. At the same time the question of damages due to Minerals Separation will be adjudicated. We have not heard as yet of any injunctions having been granted against mining companies since the Supreme Court decision.

SHAFT-SINKING is always an interesting process, particularly the methods employed in doing fast work. Two records of rapid sinking have attracted the attention of mining engineers. One of these comes from the Tintic district of Utah, where the rectangular shaft of the Chief Consolidated mine was sunk 261 feet in 31 days. The shaft has two compartments 50 by 50 inches, and one compartment 50 by 38 inches. It is protected by 8 by 8-inch timbers. Sinking progressed at the average rate of a little over 8.42 feet per day. The rock penetrated was limestone in thin layers. The total size of the rock-cutting we estimate at 15 ft. by 6 ft. 4 in., which includes 2-in. lagging and the usual allowance for clearance between the outer walls of the shaft and the rock. This indicates a sectional area of 95 square feet. The other record was made at the Crown Mines on the Rand, in South Africa, where a circular shaft 20 feet in diameter was sunk, through quartzite, 252 feet in 30 days—an average rate of 8.4 feet daily. This is almost exactly the same as in the Tintic shaft. The sectional area of the Crown Mines shaft is 314 square feet, or three and one-third times larger than the other; consequently the shaft on the Rand was really a much bigger job than the one at Tintic. However, a shaft of such large size permits of greater freedom of operations in some ways, and the effective working of a greater number of men per square-foot of area. On the Rand, too, the matter of timbering does not retard progress, as the bottom of a shaft there is often 100 feet or more in advance of the last set of timbers. Both of the shafts above-mentioned are notable examples of what may be accomplished in mining under competent supervision.

DISCUSSION this week is again varied and interesting. Mr. David Cole returns to the fine-grinding experiments at the Inspiration mill and traverses the remarks of Mr. C. T. Van Winkle, of Salt Lake City. By the way, this Mr. Van Winkle should not be confused with a gentleman of the same surname interested in the sale of a grinding-machine and resident in San Francisco. Mr. Cole finally disposes of the controversy over the test between the Hardinge pebble-mill and the Marcy ball-mill, and describes the Hardinge ball-mill, now about to be tried against the Marcy mill, which has done such good work at the Inspiration. The results of this competitive test will not prove which machine is best for all kinds of ore; but it will be most useful in suggesting a further development of this type of grinder. Our friend Mr. Jacobs, an acknowledged authority on British Columbian mines, demurs to sundry statistical statements and makes a correction of some figures quoted by us from our usually well-informed contemporary, the *Boston News Bureau*. Mr. C. S. Parsons writes from Ottawa to contribute a useful note on the use of caustic soda as a deflocculent in the flotation process, and we thank him for it. Mr. Maurice D. Leehey, as a lawyer versed in mining litigation, particularly in the Northwest, discusses the friendly controversy between Mr. Winchell and ourselves. He contends that no law can be devised that will prevent disputes over its intent and he expresses a reasonable fear that Congress may be driven to the making of dangerous experiments, more particularly the placing of our mineral lands under a leasing system—an idea that is strongly disliked throughout the West. So he cautions the mining community against insisting upon any radical change in the existing mining law. Then follows Mr. W. H. Storms, who, as a former State Mineralogist and a mining engineer of mature experience, also submits objections to setting aside the extra-lateral right. He likes the Mexican law, with its vertical planes of limitation, and the facility for locating a large area temporarily, until the locator can ascertain, by prospecting, how much ground he will require on the dip of the vein or lode. Cyanidation is represented by the letter from Mr. P. R. Whitman, who discusses the successful application of counter-current decantation at Porcupine, apropos of the excellent paper recently contributed by Mr. L. B. Eames. Mr. Whitman gives some useful data concerning similar work done nine years ago in Mexico, and we hope that his notes will provoke the former managers at the Indé to add to the information furnished by him. The 'Pertinent Questions' asked by 'A. B. C.' draw further replies from Messrs. George Jackson and S. H. Brockunier. The former records a feat in tramming that may provoke comparisons. 'A. B. C.' himself makes some practical comments on the replies made in previous issues and tells us about foremen that pooh-pooh systematic methods. We take pleasure in giving space to an appeal made by a committee of the American Association for the Advancement of Science asking for the co-operation of industrial laboratories in the great work of scientific research. The

names of the men on this committee will give weight to the appeal. An ancient topic, the black sand of the Pacific coast, receives the intelligent attention of Mr. Jacob W. Young, who writes from Alaska to describe his own useful experience in the treatment of this product. He supplements Mr. Herbert Lang's valuable article on the subject.

Metallurgy of the Rand

In this issue we are fortunate in being able to give our readers an article by Mr. H. Foster Bain discussing and criticizing metallurgical practice on the Rand. This critique is based on observations made by him during a recent visit to South Africa. It is kindly and it is meant to be useful. Evidently not much adverse criticism is possible, for a recovery of 95% of the assay-value of the ore speaks for itself, but the average reader will be surprised to note that about 64% of the gold is still extracted by means of amalgamation, although the plates are placed after the tube-mills. Mr. Bain conveys to us his own impression of the bigness of the operations by comparing the daily output of some of the leading mines of the Rand with well-known properties in the United States. He also corrects the general impression that the ore of the Rand is unusually low-grade. A \$6 ore would be considered rich at Treadwell, Juneau, Calumet, or Deadwood. The ore is relatively docile. The metallurgical problem is mechanical rather than chemical. Mr. Bain offers some interesting comment on the cost of milling, comparing it with other regions in which native labor is employed and with districts in which all-white labor is available. Apparently the chief factor in promoting economic reduction has been the development of crushing machinery to pulverize a hard ore, and this has been done mainly by the judicious use of the tube-mill so as to save the stamps that part of their duty that they are least fit to perform. Mr. Bain's discussion of the ball-mill is particularly timely, having regard to recent controversies over the use of it in copper-concentration. It has been suggested that ball-mills of large diameter, say, 10 or 12 feet, would be the most effective crushers for Rand ore. They should have steel liners, but no balls, the grinding being done by the ore itself, fed for this purpose up to, say, 8-inch cubes. The coarseness of the gold in parts of the banket has stood in the way of crushing with cyanide solution. Mr. Bain's remarks on this point will be appreciated. Even those that oppose crushing in cyanide solution, followed by amalgamation, will approve of an effort to reduce the cost of grinding to a level where it will be economical to reduce all the ore, say, to 80% through a 200-mesh screen. The logical step then would be amalgamation followed by direct treatment of the whole product in Merrill presses, as is done with the slime at the Homestake, or crushing in cyanide solution—without amalgamation—and continuous thickening, agitation, and filtering of the all-slimed product. Mr. Bain's reference to the lack of attraction of air-bubbles for particles of free gold is surprising, for our under-

standing is to the contrary. His suggestion to make a small proportion of high-grade concentrate by flotation is sound. We hope some of our readers will contribute their opinions on these matters. Coarse gold, of course, will not float if the particles are so large that gravity overcomes surface tension. The familiar needle experiment fails with a large needle. On the other hand the floatability of fine gold is one of the axioms of milling. The treatment of the flotation-concentrate by cyanidation offers sundry difficulties—such as the oil—but these are now being overcome in many laboratories and we may count confidently on a satisfactory solution of the problem. In regard to the further use of Dorr thickeners on the Rand, we are informed that it will depend chiefly upon the ability of these most useful machines to deliver a slime containing less moisture than at present. Recent experience in the United States indicates that by using Dorr trays as much as 7800 square feet of effective settling-area may be obtained from a 50 by 12-ft. vat; this is about double the settling-area of the standard 70-ft. vat used on the Rand. Such concentration of area suggests the practicability of housed vats, and the improvement of both settling and precipitation during the winter. Mr. Bain's comment on the distribution of labor between mines and mills will be appreciated at Johannesburg. We agree with him that the monotony of treating the same kind of ore year after year, and also the lack of variety in the composition of the outputs from the various mines in the district, serves to diminish interest in local metallurgical practice and to deter ambitious young men from spending many years on the Rand. We hope that Mr. Bain's pertinent criticism of one phase of the mill-management will reach those for whom it is intended. Such criticism is invaluable. We trust that the whole of his article will be taken in the kindly spirit with which, we know, it was written. In these modern days the engineer is favored with tons of descriptive matter on technical subjects—enough to provoke mental dyspepsia—but the proportion of judicious and timely criticism is lamentably small. The profession will welcome more of it; for only by aid of it is real progress attainable.

Short-Selling

The selling of shares that one does not hold has been defended lately by so eminent a financier as Mr. Otto H. Kahn, and the financial press has accepted his lead, publishing a great deal of flapdoodle in defence of an essentially iniquitous practice. The *Wall Street Journal* suggests that the market-man who sells 500 cantaloupes to the Waldorf for a coming banquet may not have a single one in his shop; he anticipates the arrival of a consignment from the South-west, in order to 'cover his shorts.' But the cantaloupe-dealer is not using the fruit as a mere counter in a gamble, he is a middleman between the producer and the consumer. The attempted analogy cannot be accepted. The *Journal* proceeds to call short-selling a "market stabilizer and a great convenience to the public"—which provokes a smile. The customers

are induced by the bucket-shop tout to 'invest' on a rising market and are encouraged to pyramid their commitments until the margin of safety is passed, whereupon the predatory broker starts selling short and smashes the quotations, making a fairly safe profit. That is why the public figures as a 'lamb' among the 'bears' on Wall Street. The simile is born of much observation. Most of such unscrupulous brokers will not take an order to sell short, because a short sale requires delivery within 24 hours and the broker is usually on the other side of the deal. The idea is to keep the greedy and gullible public in the corral until it has been sheared. On declining markets the bucket-shops go broke. In an article by Mr. Albert W. Atwood, appearing in the *Saturday Evening Post* we have an example of the way in which a mine is used as a means for such chicanery. Its value, or lack of value, played no part in the story; the mushroom brokers, their 'house organs' or circulars, a complacent press, and the eagerness of ignorant people to become rich were the factors that counted—not the mine. Such sordid little melodramas are being played every day just now. It is well that the subject should be ventilated. *The Times*, of New York, said recently: "The fact remains that short sales tend to decrease the value of another man's property." That is why the 'short' is so deservedly unpopular. A gambler that goes bankrupt on a bear deal is rated as a man that plays a mean game, for he stands to lose little and gain much, and in the gamble he may injure a great number of innocent persons. To succeed he does not hesitate to lie; in order to depreciate the stock he attacks, he employs devious ways of manipulation. The idea that his performance—or that of a 'bull'—creates industry is one of the silly myths that the broking fraternity palms upon a simple-minded public. The gambling on Wall Street no more creates legitimate industry than Monte Carlo. Speculation is the essence of adventurous enterprise, such as mining, but the risks attendant upon such useful activities are quite enough without foisting upon them the tricky gambling of a faro-table or the legerdemain of a three-card sharper.

Belgian Relief

We offer no apology for discussing a subject that must command the interest of the engineering profession in the United States not only because the members of it are the least provincial of men but because one of themselves, Mr. H. C. Hoover, has been the originator and chief executive of a noble effort "to write a page of true Americanism in Europe." If foreigners have jibed at our making money while modern civilization was being sent to the shambles, we have tried to salve our consciences by pointing to the splendid work done by a group of American engineers in Belgium. Some have solaced themselves with the idea that the American people had financed the great benefaction, but Mr. Hoover himself has disclosed the innermost finance of the Relief Commission, informing us that out of \$250,000,000 con-

tributed for the purpose only \$9,000,000 has been subscribed in the United States. As against that the Commission has spent \$150,000,000 in the purchase of supplies in this country, and on these purchases a profit of \$30,000,000 has been made, so that the United States is \$21,000,000 richer for Mr. Hoover's work. These figures might make us feel poorer in spirit if we did not return to our pride in the generous initiative and executive ability displayed by the members of our own profession in Belgium. Surely the time has come—if not too late—to give official recognition to the work. Mr. Hoover said recently that he and his coadjutors have always felt that they were "performing a national service, that it was not only a duty and a responsibility to save human life and avert suffering, but that it was a privilege to do it in the name of the American people, and to do it in a big, generous, and efficient way." Recently we made a special appeal, in behalf of a group of representative mining engineers, for funds to succor the children of Belgium. The response has been good, because many have contributed, but the amounts have been small and the big donations from rich men have been few. We quote Mr. Hoover again: "I have no patience with those who appeal only to the emotions. The man who is swayed by his emotions is usually a man of small intellect, and the man of small intellect is always a man of small pocket-book. Help we need from all classes, but our main appeal must be made to the men who have made America what it is, the big constructive men, the men of brains and wealth." With that we agree; emotional excitement will not help the little ones in Belgium, but the mining engineers and speculators that have made huge sums of money, running into millions, by reason of the big rise in the prices of metals, *they*, can help in a substantial way—and they ought to do so. Mr. Hoover says: "The justification of America's wealth can only be her requital of the obligation which comes of riches, and this requital should not be only her duty but it should be her crown." These quotations give some insight into the character of the man by whom they were uttered. He ought to be backed whole-heartedly by the people of the United States and by the Administration at Washington. Just now the work of the Commission is menaced by the rupture between this country and Germany, and by submarine piracy. If war follows, no American will be able to remain in the German province that was Belgium.

Since writing the above we have received the news that the German government has told the Commission to get out of Belgium, leaving Mr. Brand Whitlock, the American minister, and one or two others to exercise some supervision over the work. We hope that a means will be found for continuing the benefaction, but it must be confessed that the outlook is gloomy, for the confidence of the Allies that the food goes to those for whom it is intended will be lessened and the German authorities may seize the supplies—valued at \$25,000,000—now stored by the Commission in warehouses distributed among the various districts of Belgium.

The Struggle for Gold in Russia

*While the financial leaders in the United States are worried over the vast amount of gold in the country, now about \$3,000,000,000 and the steady influx, which was \$1,000,000,000 in the last two years, other countries are desperately striving to increase their store. Russia especially is worried about the leakage of gold across her frontier. This leakage is stimulated because the foreign buyer has his gold minted free while the Russian mint charges in all 8%, of which 6% is illegal. The gold produced in Russia and Siberia is surreptitiously bought by Chinese and German agents, who pay a much greater price than the Russian mint. The leakage is also stimulated by lessened smaller transportation charges and speedier returns by the foreign buyer as compared with the dilatory procedure of the Mint. Moreover, much gold is produced by 'poachers' who naturally smuggle it out of the country. The remedy suggested is for the Government to buy the gold at the place of production and pay the market-price.

Complaint is made of the unfair practice of the Mint, which is legally bound to buy gold offered in quantities of not less than a quarter of a pound and to pay for it within three days, less a fixed charge of 2% for assaying, refining, and coining. But when dealers deposited gold (in 1915) they found to their astonishment that a further deduction of 6% was made, and no explanation was given for this additional charge—it was a mere caprice. These charges and the payment for the gold at less than the market rate caused such a loss of gold that in September 1915 a council of ministers issued regulations for the payment of such a premium that there should be no profit in the exportation of gold to China, but the premium was fixed at 30%, or much less than was paid by the Chinese buyer. Hence the leakage continued. Besides paying a larger price for the gold the Chinese buyer made a settlement within a few hours while the Mint took as long as four months. One writer says that it is easy to stop the outflow of gold: all that is needed is to pay the market price promptly; but he fears that nothing can be done, for although an Imperial order was issued in October 1914 to increase the production of gold nothing had been done for a year. However, a decree allowing the free importation of dredges and their parts was subsequently issued and it is hoped that this liberal measure will increase the output.

A committee for furthering gold mining has decided that the purchase of gold must be organized in places near the mines and that, in the first instance, post and telegraph offices must be used. As a safeguard, 2% of the estimated value of the gold should be retained. Financial, economic, and judicial commissions are to be formed for investigating the gold industry. The ques-

tion of modifying gold-mining regulations and the necessity for obtaining prisoners of war for work on roads were considered. No decision was made about the free admission of Chinese laborers in the mines of Eastern Siberia; this admission was demanded by the operators and opposed by the bureaucrats.

According to an article in the *Rhein. Westfälische Zeitung*, quoted in *Zoloto i Platina*, elaborate plans for enticing gold from Russian and British producers was developed by a special commission of the German Imperial Bank. By this plan illicit-gold miners in Siberia, private buyers of gold, and agents of the German government are to be induced to collect gold for German use. German consuls are instructed to issue special appeals to illicit-gold miners in their own language and to pay a higher price than that ruling at the mines. Special agents are to be hired at a fixed commission. Private buyers are to be attracted by giving special credits and by speedy payment for the gold; and by the payment of a premium, which in July 1915 was about 1.25% for those delivering about \$10,000. German and Austrian subjects who buy gold are given large credits and stimulated by honorary titles, orders, and privileges. Buying of gold is carried on by all banks, insurance companies, post, telegraph, and telephone offices; steamer, railway, and forwarding agents; doctors, judges, pastors, custom and frontier authorities, and the Government agents that are found in all German firms; to assist in this work local consuls are obliged to open credits. Tables have been prepared, and sent to all consuls, giving the assays of gold from various districts. These tables include minute subdivisions; for example, the Amoor region is subdivided into 14 districts; Manchuria into 22; Belgian Congo into 65; British East Africa into 17 districts. This system enables the Germans to make a close approximation to the value of the gold offered. In Peking, Chefoo, and Shanghai the Germans have built permanent laboratories in which careful estimates of the value of the gold are prepared and a final settlement is then made with the sellers, who are in the first instance paid about 95% of the supposed value.

TUNGSTEN MINERALS were produced in the United States in the first half of 1916 to the value of \$9,112,000. Of this 1495 tons was ferberite, all of which came from Colorado, and valued at \$3,590,000; 1404 tons was scheelite, having a value of \$4,322,000; 201 tons of wolframite sold for \$613,000, and 185 tons of hübnerite for \$587,000.

GOLD received by the San Francisco Mint in January totaled 415,449.795 oz.; silver, 103,243.01 oz. Coinage executed was 290,000 half-dollars, 1,500,000 quarters, 320,000 dimes, and 400,000 cents. The vaults contain \$443,601,618.43. Since its inception the local Mint has coined money to the value of \$2,022,140,686.87.

Adaptation of Mining Methods to Geology and Topography

*The methods of prospecting and mining adopted by the Chino Copper Co. in the Santa Rita district, New Mexico, have been determined by the geologic features of the ore deposits, and the general scheme of excavation, ore delivery, and waste disposal has been well adjusted to the topographic situation.

By reason of the wide extent of the orebodies as compared with their depth, they were well suited to churn-drill prospecting for the determination of quantities and grades of ore. The altered and generally soft nature of the rocks resulted in low drilling costs, and the relatively even grade of the ore favored accuracy in determining its copper-content. The feasibility of open-cut mining by means of steam-shovels depends on the size of the deposits and the thickness of the overlying waste. Because the altered rocks that contain the ore and constitute the gangue are soft, drilling is easy. These rocks are much jointed and break readily when blasted. Any appreciable addition to the amount of waste material that must be moved, owing to large slides, is not anticipated. In general, the overburden of soil, or unconsolidated débris, is shallow; and everywhere such material is essentially free from percolating water. Overburden consisting of weathered rock is also well drained, and both materials stand well without 'slaking' in any important degree. Although the ore and the weathered rock contain abundant sericite, and when finely broken develop much colloidal material, in place they are generally strong enough to stand with fairly steep slopes for all depths that are reached by open pits.

The mines are situated in a basin which is a broadened section of the valley of Santa Rita creek. In plan the outline of the Santa Rita mine workings is like that of a jew's-harp, two great cuts forming the flaring loop, the block left to carry the creek forming the tongue. The creek flows south-west, leaving the ore-bearing area 4000 ft. beyond the point of entry and at an elevation 120 ft. lower. The inclined approaches that permit locomotive haulage in removing the ore from the deep pits have grades opposed to the general surface slope. These approaches diverge at a point more than 1200 ft. down stream from the western edge of the ore area. The length of haul from the far end of each of the mine pits to the common track that serves the crushing-plant is thus greater than a mile, so that considerable depths can be directly attained. Eventually spirals or switchbacks will be required, and possibly the use of hoisting-planes or Shay geared-locomotives may be advantageous. At present the development plans of the company do not contemplate that any mining will be done by means of steam-shovels below an elevation of 6050 ft., which is

approximately 150 ft. below the points where the pit approaches intersect the ground surface.

The crusher is situated near the mouth of the canyon-like valley that drains the Santa Rita basin, the delivery track being at a level about 80 ft. above the assembly yard. From this yard the ore-trains go to the concentrating plant at Hurley by way of the Atchison, Topeka & Santa Fe Railroad. Whereas the ore-tracks necessarily converge for the purpose of delivery, the waste-tracks are in the main divergent. The principal dumping-ground is in the valley of Whitewater creek, south of the mines, but most of the waste from the upper levels of the northern section has been deposited within the Santa Rita basin west and north-west of the mines.

Because of the semi-arid character of the climate, current ground-water seepage is slight in comparison with the extent of the workings, and pumping-costs are correspondingly low. At times of heavy rains the lowest levels in the pits become flooded, but little time is lost from this cause. Continued rains, which are seldom experienced, result in reduced operating efficiency, mainly by causing track troubles. For some time to come a channel for the creek will be maintained directly across the Santa Rita basin, but eventually, in order to remove large quantities of ore, the diversion of the stream will be necessary. Occasionally after heavy rains the volume of water carried by the creek is large, but the mine pits have been so planned that they are in no danger of being flooded from this source.

The Chino company has, for convenience of reference, grouped its property into six orebodies, as follows: C. Y. B., Sierra, Hearst, R. W. T., Old Fort, and Estrella. This grouping, however, is somewhat artificial and the divisions do not correspond in every case with actual breaks in the mineralized area. In fact some of the orebodies are somewhat merged with each other and some are separated by areas of mineralized but low-grade rock.

THE GOLD MINES OF THE WORLD produced, 35 years ago, in 1881, about \$103,000,000. The production for 1916 will be over \$450,000,000. The total estimated production of gold in the world to date is in excess of \$12,157,000,000, of which about \$8,000,000,000 is in the form of coin. The balance is in use in the arts, or has been irretrievably lost.

SINGLE-ARM cams permit a greater number of drops of a stamp without camming than is possible with a double-arm cam, when each has the same height of drop. All of the early stamp-mills were equipped with single-arm cams, after the iron cam-shafts and steel cams came into use.

*Abstract from Bulletin 107, U. S. Bureau of Mines.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Fine Grinding at Inspiration

The Editor:

Sir—I have read Mr. Van Winkle's discussion of my late attempt to reflect, for the benefit of your readers, the situation now prevailing in regard to "fine grinding in the Miami district," and while I deplore his attitude and tone of voice, so to speak, I believe with him that your readers may be interested in an explanation of the difference between a real Hardinge ball-mill and the pebble-mill that has been under discussion.

The particular Hardinge mill referred to by Mr. Van Winkle as "used in competition with a Marcy mill during December 1914 at the Inspiration test-plant" was an 8 ft. by 36-in. machine made with a sectional cast-iron shell, was equipped with 10-in. face herringbone gears, and was driven by a 75-hp. motor direct-connected to the pinion-shaft through a flexible coupling. The feed-scoop and throat-opening were designed to handle material previously crushed to $\frac{3}{4}$ in. or smaller. The mill was lined with pebbles set in cement. When fully loaded this machine carried five tons of flint pebbles as the crushing medium, and used 56 hp. (input to motor). The unit was served by a drag-belt classifier adequate to return the oversize when working under normal pebble-grinding conditions. The weight of this mill and motor (not including the load of pebbles) was approximately 26,000 pounds.

The Marcy machine being used in the test-mill at that time was an 8 by 5-ft. machine carrying a very heavy manganese-steel lining of the Krupp form, and using ten tons of chrome-steel balls fed to the mill at five inch diameter. The mill was belted to an electric motor and consumed 180 to 200 hp. (input to motor). The feeding devices were ample in size to 'take' coarse feed up to three inches, and the unit was served by a duplex Dorr classifier for returning the oversize. The results were

pebble-load and manganoid (cast-iron) balls were substituted. Shortly after starting with the ball-load the pebble-lining came out, and a survey of the situation showed that in order to put the Hardinge machine upon a basis wherein results would be comparative, it would be necessary to re-design it entirely; to provide first, a steel lining adapted for the use of iron or steel balls; second, gears and motor capable of standing up under the doubled load; third, feeding facilities (scoop and throat) that would handle coarse feed; and fourth, to increase greatly the capacity of the apparatus for returning oversize. To carry out this program would take more time than was then allowable and the experiment was therefore discontinued.

No engineer has previously regarded this work in the light of "competition." The management did not so consider it, and to refer to it as Mr. Van Winkle has done is absurd. References of this kind are responsible for the erroneous impression that had gone abroad, and it was to correct in some measure this obvious wrong that I was moved to write what I did under the caption 'Grinding Mills at the Inspiration' in your issue of December 9.

I have not the remotest interest in the manufacture or sale of the Hardinge, Marcy, Marathon, or any other 'fine grinder,' but I do love truth and fair-play. I know that the experiments now approaching the period of fruition in the South-west are intended to bring out the facts in regard to the competing machines and to do it with the minimum color of prejudice. The results will not be "conclusive" in the sense that Mr. Van Winkle assigns to my remarks, but to those who are confronted with grinding problems, the records about to be made will be sufficiently so for the moment at least.

The following table shows the weight, power required, load, etc., of the two types of Hardinge mill, and also the Marcy mills as being used at Inspiration at present:

	Hardinge pebble-mill	Hardinge ball-mill being installed at Inspiration	Marcy mill now in use at Inspiration
Size of mill	8 ft. by 36 in.	8 ft. by 36 in.	8 ft. by 72 in.
Size of motor	75 hp.	150 hp.	225 hp.
Weight of unit empty (with motor)	26,000 lb.	52,000 lb.	104,000 lb.
Weight of charge (pebbles or balls)	5 tons of pebbles	10 tons of balls	15 tons of balls
Power used, full load	56-57 hp.	120-130 hp.	200-225 hp.

very attractive from the first, and it was realized that the Hardinge mills that had long been in use did not in any wise provide parallel conditions, but to satisfy curiosity the mill first described was emptied of its

The 'size' of the Hardinge mills is the dimension of the cylindrical portion of the shell, and in the Marcy mill the diameter and length of cylinder are given. There is a screening-diaphragm in the Marcy machine

that shortens the grinding-chamber; therefore, the cubic contents of the grinding-chamber is less than the dimensions would indicate. In the Hardinge mill the grinding-chamber is larger than the dimensions given would indicate, because the balls or pebbles occupy the cone as well as the cylindrical part of the mill.

El Paso, January 23.

DAVID COLE.

Canadian Copper Production

The Editor:

Sir—The information relative to Canada, quoted in your issue of January 27, from the *Boston News Bureau* and purporting to "include all the mines that produced over 1,000,000 lb. of copper during the past year," is incomplete so far as British Columbia is concerned. This province is credited only with Granby Consolidated 45,484,142 lb. and Consolidated Mining & Smelting 4,446,080 lb. It may be that the latter amount includes the copper obtained from 16,400 tons of ore from the Le Roi No. 2 company's Josie group, at Rossland, and 4400 tons from the Iron Mask mine, at Kamloops, together estimated at not less than 2,000,000 lb., which, however, is doubtful. It is certain, though, that nearly 3,000,000 lb. produced from British Columbian ores through the B. C. Copper Co.'s smelter at Greenwood; about 19,000,000 lb. from the Britannia and Marble Bay mines in the lower Coast district, and between 2,500,000 and 3,000,000 lb. from the Rocher De Boule Copper Co.'s mine in the Skeena country (Omineca mining division) were not included by the *Boston News Bureau*. Deducting 28,000,000 lb. shown as the production of the Canadian Copper, which I take to be an Ontario producer, there remains a little less than 50,000,000 lb. for British Columbia's share of the total for Canada quoted by you. Figures supplied to me (by the producers) for use in making up my annual estimate of mineral production show that the output of copper from British Columbian mines in 1916 was not less than 70,000,000 lb., so I have no hesitation in requesting you to make it clear that by unintentional omission the copper production of this province last year was shown by the *Boston News Bureau* as having been about 20,000,000 lb. less than it actually was.

E. JACOBS.

Caustic Soda in Flotation

The Editor:

Sir—In the December 30 issue of your paper it is stated that caustic soda is added to the flotation pulp at the Tul Mi Chung plant of the Seoul Mining Co. in Korea. The reference goes on to say that the caustic soda flocculates the colloidal slime and allows the oil more free access to the mineral particles. My own experience has been that the caustic soda, instead of flocculating the slime, deflocculates it. The mineral particles that were locked up in the floccule of slime are set free, which allows them to be more easily oiled. Before the

caustic soda was added the oil had to penetrate the floccule of slime in order to reach the mineral particle.

Nearly all ore particles carry a negative electrical charge, hence when caustic soda is added the hydroxyl ions are absorbed into the floccules, causing them to break up and liberate any contained mineral particle.

I have experienced cases where the addition of caustic soda to the flotation pulp has not only increased the extraction but has improved the grade of the concentrate by over 300%.

C. S. PARSONS.

Revision of the Mining Law

The Editor:

Sir—I heartily commend the editorial comment in your issue of December 23 upon the proposed revision of the mining law. I regret that to do so compels me to take issue with my esteemed friend, Horace V. Winchell, for whose versatile talents I have long had such an enthusiastic admiration, and I should be sorry to have him classify me among those "shrouded in the densest ignorance of the subject." His quotation from Judge Dickson does no violence to your statement that the present law "has been filtered through the courts until its intent is clear." The intent of the law is made reasonably clear by the numerous court decisions, but it is still true, as Judge Dickson says, that "its true meaning or interpretation is still unsettled as to many questions." So is the interpretation of our national banking law and of the Interstate Commerce acts "still unsettled as to many questions," and this is evidenced by the numerous cases constantly arising under those laws. The trouble is that the advocates of general revision imagine a perfect law can be enacted, one whose language will be so clear that no disputes can arise under it. No lawyer need be told it is impossible to express such a law in our language. The framers cannot anticipate every question that may arise under a law, and even if they did, words cannot be arranged to express the rule completely and without ambiguity. And even if this could be done, it is impossible to bring about the enactment of such a law, especially under conditions existing in Congress, where such a law must be passed by men 90% of whom know absolutely nothing about mining or public-land conditions. To this situation we might apply the remarks in your last issue upon the subject of simplified spelling. No doubt our spelling could be simplified and improved, and we are just as likely to obtain an ideal system of spelling as an ideal code of mining laws.

But the great objection, from a Western standpoint, to any general revision of the mining laws at this time, is that such revision will be made by a Congress which is both ignorant and unappreciative of the fundamental principles involved, a Congress just now far less responsive to Western sentiment than it is to the influence of the well-intentioned but misinformed and impractical theorists who would place all of our public mineral-lands under a leasing system. It would surely result also in

an increase of Federal control and red tape, and limit or destroy the present power of our State legislatures to meet the varying local conditions. Really, I think we had better go slow at this time in changing a law that has stood the test of 45 fruitful years and permitted—if not fostered—that wonderful era of mining development throughout the West.

The great bulk of the unappropriated mineral-lands now left in the public domain are situated in Alaska; hence that territory is vitally interested in any new legislation. From disastrous experience we have good reason to fear any general revision at this time. We have had some trouble over the question of discovery, but so far there has been no case in the courts of Alaska involving the law of extra-lateral rights. This although Alaska, as compared with the States, has for years ranked third as a gold-producer, and now stands fifth in copper, first in tin, and either fourth or fifth in the total production of metals. The apex law has indeed been so well interpreted by the courts that counsel now has little difficulty in advising clients how to avoid its complications—no more difficulty than is presented in applying any other law, for no law has yet been written, or ever will be written, that will be free from doubt in the involved circumstances of every case which may arise under it. We are especially opposed to the bureaucratic suggestion that location notices be recorded in the U. S. land offices, of which there are three in the Territory, and the nearest often more than a 1000 miles, or three weeks, distant. We fear that any revision at this time, no matter how well considered by its proponents, will result disastrously to our interests after it has run the gamut of Congress. The coal and oil lands of Alaska are still tied up, for so far the coal-land leasing law has not proved workable, and Congress has not even passed a law permitting operations in the oil-fields. The one patented oil claim is daily demonstrating the richness of the field, but Congress has not been able to legislate for their operation, and until Congress at least demonstrates the ability to provide the much-needed new legislation for the relief of our forbidden industries, we prefer to get along with our present metal-mining laws.

Seattle, January 16.

MAURICE D. LEEHEY.

The Editor:

Sir—I have read the contributions of a number of gentlemen to this discussion, and the more I read these expressions of opinion on the subject, the more firmly I become convinced that some of them, at least, are under the impression that a change in the mining statutes that would abrogate the right to follow the dip of a vein in its downward course beyond the side line of a claim, and underneath the surface owned by another, would affect alike all mines in the West, and that there would be an end, at once, to all side-line litigation. Of course, this would not be the case, as no new law is retro-active, and only those mining claims located after such a new law became operative would be affected by it. In contemplating any change in the law that would eliminate the

extra-lateral right, due consideration must be given the necessity for following a vein downward on its dip to any depth that profitable ore may be mined.

As an illustration of this, permit me to call attention to such mines as the Kennedy, Argonaut, South, and Central Eureka, Bunker Hill, Keystone, Fremont Consolidated, Plymouth Consolidated, and other deep mines in Amador county, California. There the angle of dip of the veins is usually between 50 and 60°, and the lower workings of the mines are far out beyond the side lines of the locations that cover the outcrop of the veins. In the case of the Kennedy, which is the deepest, it is fully half a mile from the outcrop to a point vertically over the lowest level of the mine, and this distance will increase as the workings are carried to still greater depth.

In the Grass Valley and Nevada City districts the veins are much flatter than those on the Mother Lode and horizontal distance from the outcrop is gained rapidly with increasing depth. These two districts are mentioned because they may be taken as typical of veins in many other regions elsewhere—the Mother Lode fissures are in slate and amphibolite schist; the Grass Valley-Nevada City mines are mostly in granite, and conditions obtaining in these two localities are analogous to occurrences in other places, where mining locations may still be made on the public domain.

When a prospector discovers the outcrop of a vein, how will the proposed new law provide for him to follow his vein in depth, to a region, say, half a mile or more horizontally distant from the outcrop, and permit him to do so without interference with the rights of others?

It may be argued that the prospector need not concern himself about what may happen in 10 or 20 years, as he, in all probability, will never be able to carry his workings to a depth that will take him so far from his outcrop. This may be true, as to the locator, but if he sells his claim, as he is most likely to do, the only rights he can transfer to his wealthy successor are those derived from his original location. In many respects, the Mexican law, in normal times in that Republic, is superior to ours, and in none more so than in the method of acquiring title to mining property from the Government. The Mexican law provides that a prospector may, on application to the proper authority, 'denounce' (locate) for the purpose of prospecting, as many *per-tenencias* (claims) as he deems necessary, for which privilege he pays a stipulated tax or fee. He then proceeds with his investigation and when he has satisfied himself as to the number and situation of the several claims he wishes to secure, he relinquishes all of those he does not consider essential, and thereafter pays the tax only on those he decides to retain. During the prospecting period he has the exclusive privilege of searching for mineral within the boundaries of the tract selected, so he remains in undisturbed possession as long as he complies with the requirements of the law. He acquires no extra-lateral right, but is entitled to all the mineral he may discover within the planes of all his boundaries extended vertically downward. If he can

ascertain the direction of the dip of his vein, he secures in that direction what he believes to be an area sufficiently large to permit him to continue his operations to great depth. This is a law that gives to the miner all that he claims, but no more, and extra-lateral troubles are unknown. In the United States these matters require careful consideration, and when contemplating the chaos that most likely would ensue, following the proposed elimination of the extra-lateral right—if wise provision is not made to ensure the privilege of deep mining—it may be doubted if such a change is really either necessary or desirable.

There are some who say that others may acquire the ground overlying the deeper part of a vein, thus opening a line of 'deep levels,' as is done on the Rand. The argument is fallacious—there is but one Rand, its nearest geological analogy being the Lake Superior copper deposits—and the idea of creating a line of 'deep levels' and a second line of 'deep-deep levels' would not be found to give satisfaction in the West, as it would place an almost insurmountable handicap on deep mining, for only those mines producing an unusually rich ore would be considered as possibly justifying the additional expense incident to the necessary equipment, and the sinking of the deep shafts required to reach the vein at great depth, and beyond the side-line of the outcrop claimant.

Berkeley, January 17.

W. H. STORMS.

Counter-Current Decantation

The Editor:

Sir—To some of us who have followed the commercial development of the cyanide process, the successful adaptation of counter-current decantation as exemplified in the practice at Porcupine and a few other districts seems of such vital importance that data concerning it are worth preserving. Apropos of Mr. Eames' interesting article on C. C. D. in your issue of December 30, 1916, and of his comments on early attempts along that line, permit me to state that in 1908 the Indé Gold Mining Co., at Indé, in Durango, Mexico, had the continuous decantation process in successful operation. On the chance that neither Mr. Harris nor Mr. McCart (former managers at Indé) have furnished any data, I may say that the all-slimes pulp from a closed circuit of tube-mills and one of the original Dorr classifiers was thickened in three 15-ft. diam. cones, 60° sides, fitted in the centre, with diaphragm-pumps, making thirty 1½-in. strokes per minute. Barren solution was introduced into the closed circuit at the tube-mill discharge and at the classifier sand-discharge. The clear overflow from the cones, assaying two to three grams in gold and ten grams in silver, went to zinc-boxes through a Burt clarifying-filter. The average cone-feed contained 90% moisture, and the diaphragm-pump discharge 55% moisture, thus continuously decanting and precipitating 86% of the solution at its point of greatest enrichment, for, curiously enough, little further solution of gold or silver took place after the thickened

underflow went to the agitators and Butters filter. It is my belief that, at the time, we were not aware of other attempts at either continuous thickening or continuous decantation, nor did we altogether realize the full importance of the principle involved in the use of the apparatus as stated. These facts are given solely with a view to their preservation as of historical interest, the writer making no claim whatever to any credit in this connection.

Toronto, January 6.

P. R. WHITMAN.

Some Pertinent Questions

The Editor:

Sir—One of the questions asked by A. B. C. is: "How far should a trammer push a loaded car on a fair track underground in one minute?" I should say about 250 feet, or a little slower than the average walking gait. A man walking at the rate of three and a half miles an hour goes 308 ft. in one minute, so the distance mentioned—250 ft. in one minute for a trammer to push a car on a good track—is about right. However, there is a great difference in the energy that men will apply to any occupation, particularly to tramming. I knew one man who used to tram ore on contract at 4 cents per ton, from a loading-chute underground, to a mill. The distance was 600 ft. The car had a capacity of 20 cu. ft.—about one ton of broken ore. The track was straight and good—16 lb. rail—the grade was about five inches to 100 ft.; 250 ft. of the distance was underground. That man generally delivered 90 cars of ore to the mill every shift that he worked. This means that he pushed a heavy car containing one ton of ore a distance of 10 miles, and pushed the empty car back, a distance of 10 miles—20 miles per shift, and he never missed a shift for weeks at a time. Some trammer!

Sutter Creek, February 2.

GEORGE JACKSON.

The Editor:

Sir—I am pleased to see that more than one engineer has taken sufficient interest to comment on the questions I asked in your issue of January 13, though it is now evident that I should have stated in the first place, that the questions were intended to refer to the particular mine under the direction of each individual superintendent, as it would be impossible to give arbitrary answers to some of the questions that would correctly apply to all places. As an example, some of the granite in the mines of Tuolumne county is extremely hard, and no miner can drill in that rock as rapidly as in some of the softer formations of the Mother Lode. Also, it is far easier to shovel from a pile of slaty rock broken fine by blasting, than to 'buck' into a lot of hard angular blocks of greenstone, or granite, where the percentage of fine material is small, and where many of the larger pieces must be picked up by hand and thrown into the car. In such material shoveling is difficult, even from a floor, and progress is relatively slower than where the

shoveler has to handle only fine slaty rock mixed with gouge.

In my original list of questions I failed to make any reference to the size of the hat a mine superintendent should wear, as I did not realize that cranial measurement was important, but I see that Mr. Lewis thinks it is. He ingenuously states that his own hat is under seven, though from the style of his writing I think he is mock-modest. It recalls to mind the remark I once heard an old-time preacher make: "Big head, little wit; little head, worse yet."

I once knew a mine-foreman who, like Mr. Lewis, disdained to burden his mind with figures, and who frankly insisted he knew nothing of book-keeping. The superintendent called him into the office one day and showed him, on the books, that shoveling had cost two cents more a ton the last month than the average for several months past, and that the difference represented the wages of eight shovelers. The foreman declared he didn't understand it, and didn't "know nothin' about keepin' books, nowhow," and left the office. Within an hour eight disgusted shovelers appeared at the office with time-slips. The foreman was an eminently practical man, but had neglected to keep a careful eye on the smaller details of the work for which he was personally responsible; but the superintendent—I don't know the size of his hat—did have a grasp of detail and took the method above described, of teaching his foreman something of the art.

A. B. C.

Copperopolis, California, February 5.

The Editor:

Sir—I have just read the letter from 'A.B.C.' in your issue of January 13. Obviously it was intended to start something, as it is hard to believe that A.B.C. had encountered a mine superintendent too ignorant to answer his questions offhand, as applied to his particular local conditions. There is only one question that might bother one, because we do not often have to meet it or use it. It is my private opinion publicly expressed that no man is fit to be a mine superintendent who cannot answer these questions, and a great many more, offhand. They are only a few of the multitudinous questions that have to be answered by any competent mine superintendent each day.

S. H. BROCKUNIER.

Nevada City, January 29.

Research

The Editor:

Sir—The undersigned committee on Engineering of the General Committee on Research of the American Association for the Advancement of Science feels that it is timely to issue the following appeal to the industrial research laboratories of the country.

In the course of work done in the numerous industrial laboratories of America, many physical and commercial constants and data of great scientific interest and value

are doubtless arrived at, and which may, for a certain period of time, constitute an asset of considerable commercial value to the particular corporations in question. During this period, everyone recognizes the proprietary right of the industrial laboratories to the retention of this information.

A time frequently arrives, however, when such scientific information loses its commercial value (often by being duplicated in other laboratories), and just at this point we wish to impress upon the industries their obligation to enrich scientific literature with such facts and data, which might otherwise be lost or forgotten.

Some of our industries have been reproached with the suspicion of acting as sponges, in that they absorb an immense amount of useful information from scientific literature without giving any return in kind. This suspicion would be entirely removed if, from time to time, scientific information which has ceased to be of commercial value were contributed by them to its appropriate channel and thus became available to all scientific workers throughout the world.

If any doubt exists as to the appropriate channel for the publication of such scientific data and communications, the secretary of the A. A. A. S., Dr. J. McKeen Cattell, Garrison-on-Hudson, New York, will be glad to act as intermediary and to forward such communications to the proper scientific body.

A. E. KENNELLY,
J. W. RICHARDS,
A. SAUVEUR,
A. N. TALBOT,
C. C. THOMAS.

Cambridge, January 27.

Black Sand

The Editor:

Sir—I have read with interest the article by Mr. Herbert Lang on this subject in your issue of December 2. It reminds me of the somewhat intermittent investigations that I have made in connection with black sands in various parts of the country.

My idea in making the study of black sand was to see what, if any, gold was actually enclosed within the magnetic particles such as could be picked up by the ordinary horse-shoe magnet, as I had greatly doubted the accuracy of statement which I had read and heard as to the exceeding richness of some black sands, in which the gold, inferentially, if not so stated, occurred as an integral part of the black magnetic granules.

By spreading the black sand thin on a sheet of paper and passing the magnet over it, all of the magnetic particles were removed as well as some mechanically included gold and some non-magnetic minerals. By repeating the operation three or four times so as to eliminate practically all the non-magnetic material and then assaying the resultant magnetic sand, I have found that little or no gold was carried by this material. The results of the assay showed from nothing up to two dol-

lars per ton; more often than not, however, the assay was blank. On account of the tendency of the extremely thin and flaky gold to be mechanically carried to the magnet with the magnetic grains, I am loath to credit the magnetic sand with the higher assay-values obtained, as being that of actually enclosed gold particles.

Black sand from regions where platinum occurs will, after separation with the magnet and assay of the magnetic portion, show platinum in the assay. All of the platinum, however, is not magnetic.

My experience has been that the gold is in a free state, that is, mechanically mixed with the grains of sand, but it is not always bright. While the gold on the Coast, as mentioned by Mr. Lang, would have its surface apparently untarnished because of its having been subjected to recent scouring action, that in the gravel deposits situated inland which have been permeated by mineral-bearing waters and subjected to weathering agencies is sometimes more or less tarnished and discolored. In fact, it is sometimes black from iron or manganese oxides. The saving of this discolored, as well as the bright, gold, which for some reason is not readily amalgamable, is best accomplished by putting it and its containing sand through a pebble or ball-mill, thus scouring the film off the gold and causing it readily to amalgamate. This is the practice on the more modern of the gold-dredges in California for saving the fine gold that is difficult of amalgamation.

If, as Mr. Lang thinks, the gold can be concentrated into one-fifth of the original bulk of the sand by mere screening, the handling of the beach-sand at a profit would seem to be much simplified. The product from screening, if treated on the Wetherill type of magnetic separators, would give clean concentrates of the various constituents of different magnetic permeability. The non-magnetic residue would contain the gold, and part of the platinum—if any was contained in the original material. The magnetic platinum would be with the magnetite. The treatment of this non-magnetic residue for the separation of its contained gold would, in my opinion, on account of the difficulty of direct amalgamation of this sea-beach gold, be best accomplished by grinding it in a ball or pebble-mill until the gold was sufficiently scoured to cause it to amalgamate readily, and then put it over amalgamation plates.

The non-amalgamating qualities of the beach-gold may be due to a coating of oil. Some years ago an engineer who had been investigating the beach-sand mining in Humboldt and Del Norte counties of California informed me that the reason for the difficulty of amalgamating the gold in those deposits was because of the particles of gold being coated with a minute quantity of oil, derived by exudation from the underlying formations.

As regards the origin of the gold, my observations lead me to disagree with Mr. Lang. I believe that it did not originate in the ordinary quartz veins. The flatness of the particles and their extreme thinness is no evidence of an unusual origin. The flakiness is due to the abrasion to which the gold has been subjected during and after

its erosion. A fact not generally appreciated is the glaciation to which the mountainous region to the eastward has been subjected, and it is to the sliding movement of the ice that the gold owes its present physical condition. Small particles of gold when caught between the ice and the rock-surface, would be flattened almost to extinction. Flakes of similar character would also be abraded from the larger particles of gold. This finely divided and flaky gold was peculiarly susceptible to transportation by flowing water. When the ice was rapidly disappearing and vast quantities of water were being given off, the glacial gravel was subjected to sorting and re-sorting action, and the thin flaky gold, on account of its large superficial area in proportion to its bulk, was largely carried to the ocean, where it has since been concentrated in the black sand.

In the heavily glaciated regions of Alaska this extremely thin flat gold is widely distributed. While it has no economic importance, it furnishes criteria for determining the origin of gold of similar physical characteristics in other regions.

JACOB W. YOUNG.

Valdez, Alaska, December 29.

MOLYBDENITE is produced principally in Australia at present, though the outlook for a substantial production in the United States is promising. Norway produced 72 tons of molybdenite in 1914, and 87 tons in 1915. Australia yielded twice this amount. A large mass of granite containing small scales of molybdenite, ranging from 1 to 10%, has recently been discovered near the California-Oregon State line, not far from Oak Bar, in Siskiyou county, California. Molybdenite is found also in El Dorado county, California, at Grizzly Flat, and near Fairplay, in granite; in quartz, at the Kings River copper mine, in Fresno county; in the White mountains, in Inyo county, at several places in Kern county, and is abundant in some of the mines near Nevada City, and at many other places in the State, as well as in Nevada, and elsewhere. The mineral recently has attracted much attention and doubtless further search and development will result in the establishment of a new industry in the West.

THE Straits tin shipments direct to the United States have increased largely during the past three years. In 1913 the total tin shipment to the United States had a value of \$13,295,674, which in 1915 had increased to \$17,991,042. It is expected that the annual production of Straits tin will approximate 15,000 tons for several years to come. Tin production there is always directly, and sometimes seriously, affected by labor conditions. The present price of the metal is \$860 per ton. In November, 1915, the price was \$825, the highest price reached in that year.

GOLD imported (net amounts) into India during the last five years was as follows: 1916, £7,000,000; 1915, £4,017,600; 1914, £8,386,000; 1913, £18,547,600; and 1912, £27,592,900.

Metallurgical Problems of the Rand

By H. Foster Bain

INTRODUCTION. Metallurgical practice on the Rand has been described with generous wealth of detail by the men responsible for its success. Indeed Rand practice has been discussed with unusual fullness and precision in two notable volumes,¹ supplemented by numerous papers read before the technical societies; particularly a recent summary by F. L. Bosqui² which, with the succeeding discussion³ by C. W. Merrill, Hennen Jennings, W. A. Caldecott, A. J. Clark, G. H. Stanley, W. R. Dowling, and H. A. White, brings the whole matter up-to-date. It may not be wholly useless, however, to set down some of the questions that come up to a visitor as he makes the round of the mills under the courteous guidance of resident metallurgists.

Most readers of MINING AND SCIENTIFIC PRESS have not visited the Rand and probably never will. To them, there may be interest in learning how the Rand mills impress a visitor who comes to them with only that general knowledge of milling that the practitioner in another branch of the mining profession can claim. Preliminary to this the briefest possible summary may be presented of standard practice. In this I shall follow the excellent and brief summary contributed by W. A. Caldecott to the recent edition of Rose's 'Metallurgy of Gold.'⁴

After passing through either jaw or gyratory crushers, set underground to crush at 6-9 inches and at the surface to reduce to 1½-2 inches, the ore is fed under heavy stamps and thence through screens having openings up to ½ inch. From here it gravitates or is pumped to tube-mills, 5½ by 22 ft., passing through a cone, diaphragm or plain, the overflow being further split into sand and slime for the cyanide plant. The coarse material, with about 39% moisture, is crushed by means of selected hard pebbles (picked out of the conglomerate constituting the ore) passed over amalgamating plates, and returned to the first cone from which that which is sufficiently fine overflows, and, after passing classifying cones, goes to the cyanide annex. The sand is collected wet or dewatered on a sand-table and then mixed with solution, to be treated by percolation in vats. The slime is delivered to vats, where the mill-water is decanted, then cyanide solution is added and the material circulated by being pumped from vat to vat as the requisite number of washes are given. In a large number of plants this method has been superseded by the Butters system

of vacuum-filtration, too well known to require further comment here. The solution is decanted or filtered, clarified in sand-vats, and precipitated upon zinc, mainly in the form of shaving. The general results of this treatment are summarized below, the table showing averages *pro rata* to tonnage, from the records at the Simmer & Jack, Robinson Deep, Knights Deep, and Simmer Deep mines in 1913.

Ore crushed monthly, in tons	70,567
Percentage of <i>minus</i> 90-mesh product in the tailing leaving the crushing plant.....	75.4
Percentage of sand, by weight.....	54.52
" " slime	45.48
Screen assay-value, in dwt. per short ton.....	4.720
Assay-value before cyaniding, sand, dwt. per ton....	2.595
" " " " slime,	1.482
" " " " total,	2.089
" " after	0.354
" " " " slime,	0.171
" " " " total,	0.271
Percentage of theoretical extraction.....	94.26
" " " " by amalgamation.	55.74
" " " " " cyanidation...	38.52
" " actual recovery, on screen assay-value..	95.17
Total working cost per ton crushed from headgear to dump	80c.

SCALE OF OPERATIONS. Probably the first impression received by the visitor is made by the great scale of operations and the extent of territory involved. From end to end of the Rand is 70 miles, and for almost the whole distance mine crowds upon mine. It is only in the Far East, where the lode lies nearly flat, that the distance between shafts becomes impressive. Along the Central Rand there is one nearly continuous range of tailing-piles. That this impression is not incorrect is indicated by the fact that the number of tons hoisted by the mines of the Rand in 1915 amounted to 31,331,316. This is almost exactly the total of the tonnage of gold, silver, lead, zinc, and copper ores mined in 1914 in the States of Arizona, California, Colorado, Montana, Nevada, and Utah together.

It is true that 1914 was not a good year for American metal mines; nevertheless to mine and treat in one district a tonnage comparable in quantity to that produced in six of America's most important non-ferrous metal-producing States is a job that claims respect.

The scale, too, of operations at the individual plants is large as contrasted with ordinary mining. While there is nothing on the Rand that competes with the open-cut mining of iron and copper, or that equals the 3,898,100 tons treated by the Anaconda Copper Co. in 1914, or what the Inspiration is now achieving, the Rand is a district of big mining units. The four largest producers now are the Crown, Randfontein Central, East Rand

¹'A Text-Book of Rand Metallurgical Practice,' by Ralph Stokes, J. E. Thomas, G. O. Smart, W. R. Dowling, H. A. White, E. H. Johnson, W. A. Caldecott, A. McA. Johnson, and C. O. Schmitt, London, 1912.

²Bull. A. I. M. E., May 1915.

³Bull., Dec. 1915 and Jan. 1916.

⁴London, 1915, pp. 400-409.

Proprietary, and Knights Deep. How the tonnage hoisted at these mines ranks with that of a few large American properties is indicated below, all figures being for the year 1915:

Mine	Tons
Randfontein Central	2,642,357
Crown	2,558,203
East Rand Proprietary	2,006,841
Knights Deep	1,143,370
Ray	2,848,969
Calumet & Hecla	3,188,583
Treadwell group	1,652,307
Homestake	1,573,822

Each mine is operated by underground methods. Such comparisons can never be pushed far, since there is always a question as to what is a mine and what a group of mines. If only the largest of the East Rand Proprietary mines were taken into account that company would rank much lower, and if the whole of the Calumet & Hecla output from subsidiaries were added that company would perhaps head the list. The latter is now mining from 17 shafts on three lodes and producing up to 11,000 tons per day from stopes extending to 5000 ft. in depth. The new mines at Juneau, Alaska, are being opened on the basis of producing 6000 to 12,000 tons per day and the Inspiration Copper company in Arizona is already hoisting 17,000 to 19,000 tons per day from one mine. The majority of Rand mines are content with outputs of less than 75,000 tons per month. It remains true none the less that the large mines of the Rand are really big mines and that the operations generally are on a much grander scale than those to which gold miners are elsewhere accustomed. In 1915, 53 companies mined 31,331,316 tons, and after 9.62% had been sorted out, 28,314,579 tons was turned over to the metallurgists for treatment. Of the 53 companies operating, 33 had in service 100 or more stamps.

GRADE OF ORE. The second impression is, that, as matters go elsewhere in the world, the grade of the ore is fair rather than particularly low. The average for the companies reporting in 1915 was 6.18 dwt. per ton. The number of companies working upon ore of various grades is indicated below:

Dwt. per ton	Number of mines	Dwt. per ton	Number of mines
— 4	4	7— 8	3
4— 5	10	8— 9	5
5— 6	17	9—10	3
6— 7	10	+10	1

The lowest yield was that of the Glencairn Main Reef, 3.27 dwt., and the highest the Meyer & Charlton, 10.85 dwt. Both are relatively small producers, milling 251,640, and 176,410 tons respectively. The average grade and tonnage at the four largest mines in 1915 was as below:

Mine	Tons milled	Dwt. per ton
Crown	2,497,000	6.11
Randfontein	2,446,520	5.52
East Rand Proprietary	1,983,600	6.19
Knights Deep	1,217,950	3.61

How these figures compare with a few large producers elsewhere is indicated below:

Mine	Grade
Homestake	\$4.09
Alaska Treadwell	2.41
Alaska Mexican	2.62
Alaska United	2.07
Mother Lode, California	5.48
Dome, Ontario	4.80
Alaska Juneau	2.00
Alaska Gastineau	1.25
Lake Superior copper mines	2.50

The dollar is worth a trifle less than a pennyweight, but the comparison is sufficiently close for such general purposes as such figures serve. In the case of the Rand mines the figures represent the yield per ton, as is also true of the Lake Superior copper mines. The others represent the gross value per ton milled except as stated. So far as the value of the ore is concerned the Rand can hardly claim pre-eminence as a low-grade district.

CHARACTER OF ORE. A third impression is made by the relative simplicity of the ore. There is no problem of refractory ores such as metallurgists elsewhere have so commonly to overcome; along the whole of the Rand there is no smelter—that last resort of the metallurgist who has to treat sulphides, arsenides, tellurides, antimonides, or other mixtures that refuse to give up their gold to mercury or cyanide. The gold in the banket can be saved by the methods in use, amalgamation and cyanidation. The limit of recovery is an economic one; it is determined by the cost of crushing and after-treatment. If I may discriminate, I should say that the local technology is simple, it is the introduction and realization of economies that demand thought and command the admiration of the visitor.

In his introductory chapter to 'Rand Metallurgical Practice,' Stokes has given the following as representative of surface costs on the Rand:

	s.	d.	Cents
Sorting out waste	3	or	6
Preliminary breaking	3		6
Transport of ore and waste	2		4
Stamp-milling	1	6	36
Tube-milling	7		14
Cyaniding, including filling, conveying, and discharging sand (65% of pulp)	1	2	28
Slime (35% of pulp)	6		12
Total	4	5	\$1.06

These figures do not include general and head-office expenses, which are stated separately and amount to 1s. 6d. or 36c. per ton. Caldecott gives the following as the average cost of treating 3,387,000 tons of ore by four companies controlled by the Consolidated Gold Fields company in 1913:

	Pence per ton
Transport of ore	2.773
Breaking and sorting	3.258
Stamp-milling	10.512
Tube-milling	8.340
Sand-treatment	9.113
Slime-treatment	5.988
Total	(£0.80) 3s. 3.984d.

While comparisons, from one district to another, are

of questionable value, because of difference in conditions and in methods of stating results, the following costs of treatment at mines in other countries may be cited. In each case the mines yield gold ores and the process is either one of amalgamation followed by cyanidation or by concentration with some form of after-treatment. Except as indicated, the costs are quoted from 'Mining Costs of the World' by E. N. Skinner and H. R. Plate.

The Homestake mine in South Dakota in 1915 treated 1,573,822 tons of ore by amalgamation and cyanidation, employing 1020 stamps. The company publishes its costs in unusual form and in order to get at milling costs per ton it is necessary to work back from tonnage and total charges. On this basis the total cost amounts to about 44.3 cents per ton, the items⁵ being as below:

	Cents
Milling	24.25
Re-grinding	0.81
Sand treatment, leaching (in tanks)	10.81
Slime leaching (in filter-presses)	8.42

44.29

These figures represent costs per ton milled. In a careful review of Homestake metallurgy⁶ Allen J. Clark gives the following as the cost of each stage of the process, based on the tonnage treated at that stage:

	Cents
Stamp-milling	24.25
Re-grinding	12.64
Sand-treatment	17.72
Slime-treatment	18.38

The summation of these is not the cost per ton, for which figure the 44.3 cents already derived is more nearly correct. If a complete distribution of general expense were made, the total would be slightly increased. At the Homestake white men only are employed and, as on the Rand, all the material passing the amalgamation plates is cyanided.

The Treadwell group includes four mines, dropping 960 stamps in all. Only white labor is employed. Amalgamation is followed by concentration and cyanidation of the concentrate. According to the report of P. R. Bradley for 1915, the total cost of treatment ranged from 37.58 to 41.39 cents per ton. The details for the properties were as below, stated in cents per ton:

	Alaska Mexican	Alaska Treadwell	Ready Bullion	700-Ft. Claim
Milling	30.56	31.22	29.32	27.35
Concentrate treatment..	9.81	9.34	9.37	9.49
Bullion charge	0.69	0.83	0.87	0.74
Total	41.06	41.39	39.56	37.58

The Mother Lode mines of California are working at various depths down to 4000 ft. and treating the ore by amalgamation followed usually by concentration, the concentrate being in turn subjected to cyanidation, chlorination, or smelting. The units of production are small as compared with the Rand. All the labor is white. According to figures compiled by Charles Janin⁷ the

A TAILING-WHEEL

CYANIDE VATS

FERRO-CONCRETE FOUNDATIONS

⁵M. & S. P., April 1, 1916, p. 495.

⁶Bull. A. I. M. E., July 1915.

⁷M. & S. P., October 26, 1912.

milling cost ranges from 24 to 55 cents at seven of the better known properties though higher in the case of two others mentioned. At the most progressive mine, the Plymouth Consolidated, the cost of milling is 32 cents.

Turning from the districts in which all the labor is white, I may cite the cost incurred by the Indian and Korean mines, in which natives work under white supervision. Representative Indian costs are as below:

	Milling		Cyaniding		Total	
	s.	d.	s.	d.	s.	d.
Mysore, 1912	2	2.76	1	2.16	3	4.92
Ooregum, 1912	2	1.80	1	9.24	3	11.04
Nundydroog, 1912	1	10.44	1	3.60	3	2.04
Champion Reef, 1911 ...	2	5.88	1	8.76	3	14.64

These totals range from 76 to 94 cents per ton.

The Korean sets of costs are as below, the figures being in cents (American) per short ton:

Mine	Milling	Transport to mill	Concentrate expense	Total
Oriental Con.	47	..	19	66
Seoul Mining Co. ...	62	5	24	91

Consideration of these figures leads to the surprising conclusion, in which probably too much confidence ought not be placed, that even in milling, where machinery counts for so much and labor is relatively unimportant, it is only in the countries where native labor is employed that treatment costs are generally as high as on the Rand for ore that requires somewhat similar treatment and when the quantity handled per unit is of approximately the same order. It may be well to repeat that such comparisons are not to be pushed too far and instances of higher milling costs in 'all white' countries may be cited, such as the Dome in Canada, where in 1913 the total ran to \$1.65;⁸ Waihi in New Zealand, which had a milling and cyaniding cost of 5s. 11d. in 1912; and the Goldfield Con. in Nevada, where in 1915 the total for stamp-milling, concentrate treatment, marketing concentrate, and bullion came to \$1.42 [of which 29c. was for cyanide and 39c. for water]. Probably all that one can fairly say is that Rand milling costs, while creditable, do not seem to have been lowered particularly by the presence of native labor and are not remarkable in view of the heavy investment in plant. This may be necessary and unavoidable, having in view the nature of the ore and the conditions under which the work is done, but it comes to the visitor as a bit of a disappointment. It may be helpful to try and diagnose the cause.

THE COST OF TREATMENT depends upon (1) the nature of the ore; (2) character and cost of labor; (3) cost of supplies; (4) cost of power; (5) scale of operations.

It is clear that the character of the ore determines the treatment. The choice of method and of machine is limited by it. I have already indicated that the ore is simple in composition and does not require complex methods. The gold is 'free' if only the containing rock and pyrite be broken, so as to expose it to mercury or cyanide. The main difficulty is to so break it. In the table of costs of the Consolidated Gold Fields properties already given, it may be noted that breaking and sorting,

stamp-milling, and tube-milling together account for nearly 60% of the total. Since the Gold Fields costs are among the lowest on the Rand, and since at these properties sorting has been reduced to a minimum, it may be taken the hardness of the ore is the cause of the great expense in milling. In hand-specimens the banket shows as a dense dark mass set with glistening quartz pebbles between which is a silicious matrix containing a minor proportion of pyrite. The whole is so thoroughly cemented that it is extremely rare to find the rock breaking around a pebble, and in examining large heaps of spent 'pebbles' from the tube-mills I have not seen one that showed material difference between the wear of the quartz pebbles proper and that of their matrix. The banket is 'frozen' tight to the quartzite that lies above and sometimes is interbedded with it, and the whole has become one thoroughly cemented mass. In view of these conditions the Rand metallurgist has rightly concentrated his attention upon crushing machinery, and by adding the tube-mill to the stamp he has achieved success. The average duty in tons per 24 hours for the 9396 stamps at work in 1915 was 9.53 tons. Details for a few Rand properties are cited below:

Mine	Stamps	Tube-mills	Duty per stamp
Con. Langlaagte	98	10	22.78
Van Ryn Deep	80	8	21.44
Modderfontein Deep	60	6	21.36
Government Areas	98	10	20.88
Rodepoort Un.	75	4	17.05
Modderfontein B.	96	5	15.26
Geduld	60	5	14.88
Brakpan	145	10	14.84
City Deep	153	9	14.33
Simmer Deep	193	9	13.76

Despite these excellent results, and because of the high proportion of cost chargeable to crushing, there is no subject that attracts more attention on the Rand than the possibility of improving this branch of the practice. The gold occurs in the matrix partly in the quartz and partly in the pyrite. It is native and the ideal method of crushing would seem to be to crack the gangue away from the metal. This, it will be recalled, is the problem in the Michigan copper mills, where the steam-stamp has obtained such a dominant position. The thought of applying steam-stamps is not new and a series of 500-ton single units sounds attractive. When, years ago, attempts were made to domesticate the steam-stamp at the Homestake preparatory to introducing it generally in gold-milling, it was rejected largely on the basis of the increased amount of slime produced. That would now be an advantage, and the question arises as to whether there is not now scope for such stamps. The subject has been so well discussed by T. T. Read,⁹ and Algernon Del Mar¹⁰ in two papers easily available that I shall not repeat details. It is sufficient to say that conditions, in particular the presence of relatively large particles of metal held much less firmly in its matrix than the gold of the Rand banket, have been responsible for the wide vogue of

⁹M. & S. P., February 25, 1915.

¹⁰*Ibid.*, October 3, 1914, p. 513.

⁸Now 77c. on 40,000 tons monthly.

steam-stamps in Michigan. As steam-users they are not economical save when supplementary devices have been introduced such as compounding or low-pressure turbines following the stamp. While upon the Rand the waste-steam would find a use in heating solutions to facilitate precipitation by decreasing the viscosity, the best local opinion is to the effect that progress will hardly be in the direction of such an innovation. This is all the more interesting in view of the great improvement resulting from the increased weight of the ordinary stamp¹¹ and the introduction of the Nissen. H. C. Behr has a project for meeting the difficulty by introducing a pneumatic stamp, in which the air, used at high pressure, is only partly expanded and then returned to the compressor. In theory such a stamp shows marked power economies but it has not yet been tested in practice.

BALL-MILLS. The alternative for stamps is some form of rolls, edge-runners, or ball-mills, and many of these have been tried. So far all have proved to consume so much steel as to off-set what other advantages they show. This is imputed by Caldecott to the fact that all of them introduce abrasion, which is interesting, since about two-thirds of the crushing on the Rand is now done in tube-mills, where abrasion is most important. The figures already quoted demonstrate that the crushing done in the tube-mill costs less than that accomplished by the stamp, a fact fully appreciated on the Rand, where the tendency is to throw more and more of the work on the tubes. The explanation of the paradox is the fact that the 'pebbles' in the tube-mills are merely roughly rounded pieces of ordinary banket. Their abrasion is therefore a benefit rather than the reverse. If the work now done were accomplished by means of steel, or even barren chert pebbles, the economic ratio would be seriously disturbed.

In Canada and the United States the ball-mill has been gaining ground recently at the expense of stamps. The reason for the renewed interest lies in improved methods of discharge, as in the Marcy mill, coupled with the sizing action of the conical shape in the case of the Hardinge. At a number of mines where competitive tests have been made, ball-mills have been substituted for stamps both on the basis of economy of floor-space and of lower power consumption. At the Dome, where C. W. Dowsett, formerly at the Brakpan, is mill-superintendent, Hardinge ball-mills are being substituted for stamps to crush 3 in. material to $\frac{1}{4}$ in., with 50% passing 100-mesh. For this purpose an 8-ft. mill, 30 in. long, driven by a 125-hp. motor, is used. C. D. Kaeding, the general manager, states that the steel consumption from balls is 0.22 lb. per ton and he estimates the liner consumption at 0.60 lb. At the McIntyre a 6-ft. mill showed a total steel consumption of 1.03 lb. per ton. This may be compared with half a pound per ton with stamps on the Rand.¹² In this connection it may be mentioned that extensive trials completed some time ago on the Rand with the Giesecke, a double-chambered tube-mill, showed a quite prohibitive consumption of steel balls. As the ore in the

ROBINSON CENTRAL DEEP

SAND DISTRIBUTOR

STAMP-MILL FOUNDATIONS

Porcupine district is a comparatively soft though tough schist, the Dome metallurgists are not willing to commit themselves as to what a ball-mill would do there. In this connection a word of caution may be appended as to the results of short-time tests. As balls are usually made, by forging,¹³ they are much harder on the exterior than through the whole ball. A new charge therefore gives better results as to steel consumption than a true average.¹⁴

Another machine which is attracting attention for intermediate work is the disc-crusher. This has the advantage of great freedom of discharge, since the ore is fed through the centre and the material passes out around the circumference of a circle, the action being rendered positive by employment of centrifugal force. It also has the advantage, which may prove important on the Rand, that the crushing is not accomplished by rolling or abrading, but by pinching or nipping. The action is similar to that in a jaw-crusher since the two horizontal revolving discs are set slightly eccentric to each other so that the two rims approach and recede as do the jaws of an ordinary crusher. One of the disc-machines has been used in crushing waste-rock on the Rand for road-making. Last spring the Mines Trials Committee began a series of tests upon it to determine its availability for regular work in the mills. The preliminary figures showed remarkable results as regards quantity of material handled and power consumption, but the excessive consumption of steel was found to offset all other advantages, and the disc-crusher was condemned as wholly inapplicable to Rand ore.

AMALGAMATION. If the hardness of the ore is a serious detriment to low crushing-costs, the fact that the gold is 'free' simplifies the succeeding treatment. Despite various changes, amalgamation still plays an important part in the recovery of the gold, although the use of coarse screens in front of the stamps has necessitated the transfer of the plates to a position below the tube-mills. At the Homestake mill, Clark has shown¹⁵ that from 86 to 91% of the amalgamation is accomplished in the mortars and on the first two rows of plates, and it is common experience that the bulk of the gold is saved near the head of a string of plates. On the Rand amalgamation in the mortars has long been abandoned and the plate-area greatly restricted. It was, I believe, Mr. Maxwell at the Randfontein who first made a radical reduction in plate-area, but the practice has now become general, the minimum being in the Gold Fields mills, where there are only three plates of 4½ by 12 ft. area per tube-mill circuit. It has been found that the consumption of mercury is proportionate to the plate-area exposed, but the recovery of gold is not. With the efficient cyanidation plants now in use there has been no increase in tailing-losses in consequence of reducing the plate-area. Of the total value recovered in 1915, namely, £37,264,992, amalgamation was responsible for £23,809,801, or 64%.

Contrary therefore to the general impression, amalgamation is still much more important than cyanidation on the Rand. It is a bit surprising to contrast the small area devoted to plates and the big yield from it, with the acres of vats and other plant devoted to cyanidation. It is easy to see why local metallurgists hesitate to adopt any method that interferes with amalgamation; all the more in view of the fact that while the bulk of the gold exists in the rock in very fine particles, coarse gold is present and often in amounts sufficient to threaten serious tailing losses if the present system of cyanidation alone were relied upon.

CRUSHING IN CYANIDE. It is this that has stood in the way of crushing in cyanide, despite the great saving that might be realized if the process were adopted. The objections are mainly the corrosion of the plates and the difficulty in sampling. Minor objections are the necessity for handling a baser bullion due to the cyanide dissolving copper from the plates, the need of a more expensive cyanide treatment, and the increased liability to loss from leakage. It is just possible that these difficulties are not so serious as has been thought. It was in 1892, I believe, that the process was tried at the May Consolidated and condemned, and much has been learned since that pioneer date. It has been my general observation that in mills where crushing in cyanide is practised the trouble with the plates is much less important than had been anticipated. At the Lonely Reef only a few months ago I was told that there was no trouble. While, owing to the small plate-area used on the Rand, amalgamation practice differs a little from that in other districts, it is still not easy to see why there should be any corrosion beyond the control of capable metallurgists. Remembering the years that shaking plates were built on the Rand because of some early experiments, only to be found later unnecessary and abandoned, and recalling various metallurgical experiences in other districts, the visitor wonders whether by chance this is another instance where a thing is believed to be impossible because it has not been recently tried.

SAMPLING. The cost of this can be overcome if it be considered worth while. It is true that reliance upon lip-samples, as at present, would not be safe, but even now lip-samples taken at intervals of six hours seem woefully inadequate, despite most convincing tabulations and records. The miner makes up his figures by combining stope-samples. The mill-man depends upon lip-samples taken at the mortars. The two do not check and there is the same feud between mine and mill on the Rand as in other districts. Even lip-samples taken in different sets in the same mill do not altogether check and it is only the blessed law of averages that saves the situation. If it be judged of sufficient importance it would not be difficult as a technical matter to take a complete sample ahead of the stamps where at most Rand mills the whole stream of ore is re-united after passing through the ore-house. At the point where the main belt delivers to the movable cross-belt, which in turn delivers to the ore-bins, an automatic sample of any desired size

¹³Now mostly cast-steel. However, the comment holds good.

¹⁴For general discussion see articles in M. & S. P. by H. C. Cutler, February 5, and Henry Hanson, March 13, 1916.

¹⁵*Op. Cit.*, p. 1385.

could be diverted and, after being mechanically quartered down, returned to the stamps. Especially in mills where plates have been taken out of old structures there is room that could be used for a sampling-plant, and in any new mill proper space could easily be secured. The methods of mechanical sampling and weighing are so well understood that it is hardly necessary to quote details. At the Washoe mill of the Anaconda company a larger tonnage than that treated by any Rand company is handled and the ore has long been regularly sampled in a plant built by D. W. Brunton. At normal prices for metals the gross value of the ore at Anaconda is less than at a considerable number of Rand mines, including such properties as the City Deep and Ferreira Deep. The ore comes to the mill at Anaconda in a condition as regards coarseness, irregular moisture content, and other features not greatly different from the Rand ore as usually delivered. Mechanical sampling is feasible if it be considered worth while. It must be admitted, however, that with the later development of Rand milling, where the pulp travels in a series of impinging circuits with its escape from one to the other controlled by the accuracy of exceptionally good classification, there is some justification for the dictum of Rand metallurgists that it is far less important to know what gets into the mill than what leaves. A reasonably accurate method of sampling the feed may be accepted so that more time and attention may be devoted to greater accuracy in determining the product and the tailing.

Whether crushing in cyanide would unduly increase the expense of cyanidation itself, or, with proper safeguards, seriously add to losses from misdirected solutions, I make no attempt to determine. Possibly further study on these points would reveal methods of meeting the situation.

CONCENTRATION. At various times proposals have been made for supplementary amalgamation by concentration and before the cyanide process attained ascendancy large sums were spent on tables, vanners, and other concentration devices. This has all been given up. The plan breaks down before the simple fact that the gold occurs not only in the pyrite but in the quartz. If therefore all the sulphides in the ore were concentrated successfully there would still be a heavy loss of gold in the uncrushed particles of quartz. When the material is crushed sufficiently fine to release the gold in the quartz it is also released from the pyrite and open to attack by either mercury or cyanide. By a fortunate circumstance the arrangement of dewatering and sizing cones in the tube-mill circuit is such that the particles of pyrite are subjected to more crushing and longer treatment than the quartz, so that there is added opportunity for release of the gold.

The objections to ordinary wet concentration would apply equally in the case of flotation, and would even be stronger, since the air-bubbles are not known to have any affinity for gold. At the Falcon mines, where flotation is used, the greatest care is exercised to save the coarse particles of free gold before the pulp goes to the

flotation-cells, and this would be necessary on the Rand as well. So far as present knowledge goes there seems little reason to expect that it will prove feasible to use flotation as a supplement to amalgamation alone and so to substitute a simple compact plant for the acres now devoted to cyanidation. If flotation be introduced it seems best to use it as a supplementary process for treating the sand or slime after cyanidation. According to J. E. Thomas,¹⁶ the pyrite, while constituting but a small percentage of the residue, contains from 6 to 10 times as much gold. It is worth investigating whether it would not be possible by flotation to produce a small amount of relatively rich material here, operating with a high concentration ratio. This is all the more possible since in South Africa the sulphur as well as the gold in any such concentrate would probably be of value. It is said that in the Black Reef there are considerable bodies of low-grade pyritic ore. Formerly attempts were made to work them by wet concentration, though with no great profit, according to report. Some work is being done now. It is possible that here also is a field for flotation.

In the work of cyanidation as practised on the Rand, among the striking characteristics are (a) the large use made of centrifugal pumps; (b) the perfection of the sizing and classification; (c) the persistent use of decantation; (d) the employment of zinc-shavings for precipitation; (e) the growing use of vacuum-filters for slime-treatment.

TAILING WHEELS are giving place all along the Rand to centrifugal pumps, which are being used for elevating materials from the finest slime up to $\frac{1}{2}$ -inch stuff. The pumps cost less, and while operating charges are higher, they have the great advantage over wheels that changes in plan requiring a higher lift do not necessitate scrapping the whole plant. The wear on impellers and liners is naturally heavy with coarse material, and so far no quite satisfactory system of reinforcement has been devised. At the Geduld hard iron liners last about 26 days. Probably this need will be met in time by building small foundries at the mines and re-casting scrap. This is done with good results in Rhodesia. At the Lonely Reef only one skilled white man is employed on the work, but melts are made twice a week and many shapes, including pump-parts, are cast. The cost is 4 to 5c. per pound and the scrap is used over and over. A similar system of relying on cheap material frequently re-cast has been found applicable at Joplin, Missouri, and in many districts where better material of longer life would be, as on the Rand, unusually expensive.

The work of dewatering and classification is conducted on the Rand on a big scale and with excellent results. Cones, especially the delightfully simple and effective diaphragm-cone invented by Caldecott, are much used. These are often supplemented by the sand-table, which was also designed by him and which proves most satisfactory in operation. These features of Rand practice have been so well described that I need merely mention them.

¹⁶'Rand Metallurgical Practice,' Vol. I., p. 181-182.

DECANTATION is another process that has achieved unusual prominence on the Rand. To the visitor it is one of the most impressive features of local practice. To settle slime to a 40% moisture content, in great quantity and within the time limits that may be allowed in practice, is an achievement indeed, and however much one may go to the Rand prejudiced against a discontinuous process of this type, he is bound to return with the feeling that there is much to be said in its favor. In other regions the whole trend is toward continuous processes made as automatic as possible, and it may be noted that in the plans for the new Modderfontein mill the slime treatment will be along this line, with Dorr thickeners such as are used so generally in Canada, the United States, and Mexico. In this connection it may be pointed out that even in a country of low-priced labor, metallurgical results and costs seem to gain by substituting machinery for men where possible. The mills on the Rand that treat the lowest grade of ore, and at the most favorable cost, are the very ones where the fewest men are seen.

Supplementing decantation by vacuum filtration is now recognized as standard practice for new plants. Filters have been added to a number of old ones. While the additional recovery has not shown as high a profit as was anticipated, there is still sufficient profit to justify the added investment. It should be remembered that a final tailing worth only 0.25 dwt.—and that is what Rand metallurgists work toward—does not leave much margin. An actual recovery of 95 to 96% on ore of the grade treated on the Rand must be conceded to be satisfactory.

Precipitation is still done by means of zinc-shaving. The pros and cons of zinc-dust precipitation, which has so generally replaced zinc-boxes elsewhere, have been stated in detail by Bosqui. It may be pointed out that the choice of method on the Rand is not wholly governed by technical conditions, though the weakness of the solutions is a factor. So long as it is a settled policy to show the same clean-up per month without very close regard to the grade of the ore milled, it is a matter of great convenience to have in the hundreds of zinc-boxes a reservoir that may be used as a regulator.

COST OF SUPPLIES. The Rand, owing to its distance from manufacturing centres, is a district in which cost of supplies is unavoidably high. The total amount expended in the Transvaal in 1915 for such supplies as are listed by the Government Mining Engineer was £10,889,115. This may be compared with the total of white and native wages and salaries, namely, £13,501,291. It is difficult to segregate the mill-supplies. Caldecott gives the following as the average consumption of metallurgical stores per ton of ore milled by the Consolidated Gold Fields companies in 1913.

	Pounds
Mercury	0.0664
Lime, 75%	2.1822
Sodium cyanide (130%)	0.3072
Zinc	0.3965
Lead acetate	0.0487
Bisulphate of soda	1.4805

The total amount expended on the Rand in the same year for purchase of the chief mill-supplies is listed below:

Cyanide	£538,366
Zinc	234,330
Lime	124,850
Shoes and dies	159,552
Tube-mill pebbles, liners, etc.	56,361
Mercury	34,435

These few figures sufficiently emphasize the importance of careful buying and, back of that, of systematic and thorough study of the quality, uses, and possible substitutes for each material bought. Since the War began, great progress has been made in this direction, and various inter-mine committees are now at work looking for substitutes or methods of decreasing the amount used per ton. From their work important technological assistance may be expected. The Consolidated Gold Fields maintains, under the direction of A. McArthur Johnson, a testing-laboratory that is of much service in setting standards for supplies.

COST OF POWER. Most of the mines now buy power through the Victoria Falls Power Co., which maintains steam-generating stations, transmission mines, and pipes for distributing electricity and compressed air. Where individual power-stations are maintained at the mine there is a by-product in that the waste-steam is used to warm the solutions and so facilitate decantation. That this is not more general is due to the fact that the purchase of current is so common. South Africa is fortunate in possessing abundant coal that may be cheaply mined. This, with the excellent character and large size of the generating-stations, results in low charges for power. Contracts are made for 12 and 20 years and current is furnished at 2100 and 525 volts. The consumer supplies a sub-station building and pays an additional 2% on his bill to cover losses in transforming and stepping-down the current, but the switches, transformers, and other gear are furnished by the power company. The standard and price on a 12-year contract is 0.515d. per unit so long as the monthly load-factor is 70% or better. The price is subject to revision under certain contingencies as to cost of production, and there is a penalty of 7s. per hour per 100 kw. for failure to supply current. Actually there are remarkably few stoppages, since the power company draws from several stations and has a network of transmission lines. The largest station is at Vereeniging, where the Vaal river furnishes abundant water for the condensers and the New Cornelia Colliery supplies coal. The plant is equipped with mechanical stokers, water-tube boilers, and every device for labor-saving. It is, I believe, the fourth largest power-station in the world and supplies about 25,000,000 electric units per month to the system, using about 3% of its gross output to move its own machinery. About 5% is lost in transmission. The coal consumption varies from 1100 to 1300 tons per day, depending upon the proportion of total load assigned to this station, and, despite the fact that the coal is high in ash, the generating cost is the lowest of that at any of the company stations.

It is planned to increase the plant to a size that will demand 60,000 tons of coal per month. Thanks to the excellent manner in which the scheme has been carried out the company is a profitable enterprise despite the low price at which current is sold. In this particular the Rand mines are fortunate.

LABOR PROBLEMS. The mills have a constant fight to keep from having an undue proportion of the least efficient men passed to them. A poor workman underground is a danger to so many aside from himself that naturally and properly the tendency is to make a place for him at the surface. Here he is often able to work effectively, but it is not a rule without exceptions. Native labor at best has many drawbacks and can hardly be expected to show high efficiency, but in its distribution the mills get the worst of it. The same is true to some extent of white labor, and many a man contrives to keep his connection with the pay-roll in a mill who would be dismissed even by a Rand shift-boss, who is usually so short-handed that he becomes extremely long-suffering. In most mining districts the pressure is for jobs at the surface and the bright young men from the schools of mines feel that there is better opportunity for them to use their technical knowledge above than below ground. On the Rand a larger part of the best technical graduates go underground for the reason that there is no other route to the coveted position of mine-manager. Attempts have been made to balance matters by creating the position of Reduction Works manager with control over both stamp-mill and cyanide annex, with a salary corresponding. So far this has not been widely done and most mill-men reach the limit of promotion and pay in a few years. After that the life is not especially attractive because of the monotonous routine. A Rand mill, handling always the same ore, artificially kept as nearly as may be to a predetermined grade, does not offer much field for novelty. In certain organizations the disagreeable conditions are made worse by the line drawn between the operating man at the mine and the head-office metallurgist. The operator is not unlikely to get into the attitude of dodging responsibility. The mill is handed to him complete, he has no part in its design or erection, and if changes are made they will be determined by the head-office man. It is not unnatural, however deplorable it may be, that some of the men drift into the mental state where they reason that so long as they suggest nothing they will not be responsible for a failure and so long as they keep the other man's plant going even reasonably well, they are sure of a comfortable job. With neither increased pay nor credit to gain, why take responsibility for suggesting any change? I would not imply that all the mill-superintendents adopt or act on any such ideas, but the feeling is present on the Rand and shows in the work. The consulting metallurgists as a class are a fine type and have been wonderfully skillful in preventing the growth of this feeling among operating men, but it is not an easy task where lines are drawn so sharply between operation and design and where the rewards on the two sides of the line differ so greatly.

The isolation of the district is a great handicap. Many

of the men in the mills have never seen any other metallurgy than that of the Rand. They are extremely narrow specialists and it is difficult to see how this is to be avoided. The leading men keep in touch with practice around the world, but the subordinates cannot afford to do so on their incomes and they do not have the opportunity, open in most great mining districts of quitting and going elsewhere. How much this factor of isolation affects costs it is impossible to say, but that it does do so is patent. This brings out again the old fact that regardless of the character of the ore, the cost of power, or the type of plant, the human factor enters into milling, and to its consideration many anxious hours must be devoted by the chief on whom falls the main responsibility.

The Source of Copper in Gold Bullion

Copper is nearly always present in gold bullion derived from amalgamating in mills. The source of most of this copper is the detonating caps used in blasting. The amount will vary greatly, depending on the ratio of shots fired to the tonnage of ore milled. In some mines every ton of rock broken is the direct result of one or more blasts. In other mines, the method of mining and the character of the ore, or its condition, are such that many tons can be obtained without firing a shot. In a mine that produced and milled 5000 tons of ore monthly, 1500 shots placed in ore were fired. Many other shots were in waste, but assuming that the greater part of the copper of the detonators fired in stoping mixed with the ore and went to the mill, then this copper, which was still in metallic form, amalgamated, together with the gold, and most of it entered the bullion. The copper in 500 detonators of the usual size weighs about one pound, and the 1500 caps exploded in a month then weigh three pounds avoirdupois, which is equivalent to 47.74 troy ounces. The ratio of copper to gold depends on the amount of amalgamable gold in the ore, so the proportion of copper entering the bullion may be relatively great or small. Comparatively little copper in mill-bullion is derived from the abrasion of plates, or from pieces of plate that may be broken off in the battery, or from copper screws, or other copper articles that find their way into the mortar, for these are usually seen and removed when cleaning the amalgam. Scarcely any copper comes from the ore. The lead so often found in the gold-sponge taken from the retort can generally be traced to pieces of babbitt that fall from the cam-shaft boxes, or from the spindle of the rock-crusher.

INDIA is a large producer of both manganese and tungsten ore. The output of manganese ore in 1915 was over \$4,500,000 and of tungsten, \$1,444,000.

ALUMINUM MONEY was issued by the Chamber of Commerce of Marseilles, France, during 1916. An issue was also authorized by the German Government.

The Minerals Separation Campaign

Herewith we publish, for what interest they may offer to our readers, the letter sent by the Minerals Separation company to those not licensed by it and the list of questions that the latter are requested, or commanded, to answer.

January 22, 1917.

The Blank Mine,
Blankville.

Gentlemen: In behalf of my clients, Minerals Separation, Limited, of London, England, and Minerals Separation North American Corporation of 61 Broadway, New York, N. Y., you are hereby notified of infringement of my clients' patents for froth flotation concentration of ores, and particularly the basic patent for such a process, No. 835,120, issued November 6, 1906, to Sulman, Picard and Ballot, recently held to be valid and infringed by the Supreme Court of the United States in the case of Minerals Separation, Ltd., and another against Hyde. I am enclosing a copy of the opinion and order of the Supreme Court and of the decree and injunction affirmed thereby with immaterial modifications. My clients are willing to grant licenses to those who wish to use their inventions, but before any consideration can be given to that matter, a full settlement for past infringements must be made, and this altogether regardless of whether or not you wish to continue to use flotation.

You are therefore hereby directed to send to me a full statement of your infringing operations in accordance with the interrogatories enclosed herewith, in default whereof I am directed to commence suit against you for an injunction, profits and damages, including a preliminary injunction at the commencement of the suit to immediately stop your infringing operations.

Yours, etc.,

HENRY D. WILLIAMS.

STATEMENT OF FLOTATION OPERATIONS

1. Name of Company.....
2. Where incorporated
3. Home office address.....
4. Name of mine.....
5. Mine address
- 6(a). Is mine in operation.....
- (b). Is mill in operation.....
- 7(a). Present daily tonnage.....
- (b). Expected daily tonnage.....
8. General character of ore.....
9. Principal sulphide minerals.....
10. Principal gangue minerals.....
11. Type and daily capacity of milling plant.....
- 12(a). Is the flotation process in use or has it been used, experimentally or otherwise, in this mill.....

- (b). For how long.....
13. What products are or have been treated by flotation
14. What is the total mill recovery.....
15. What proportion of total recovery is due to flotation
16. Number of tons treated daily by flotation.....
17. Total tonnage treated by flotation to date.....
18. Total concentrates produced by flotation to date
19. Average assay value of flotation concentrates....
20. Gross market value of all flotation concentrates produced to date in this mill.....
21. Type and manufacture of flotation apparatus used in this mill.....
- 22(a). Have any flotation tests been made on this ore...
- (b). If so, by whom.....
23. On separate sheet, give complete details of flotation tests made.
24. Remarks
- Dated Signed
- Title.....

MOLDING-SAND is used in foundries, and as the name signifies is employed in molding the forms into which the molten iron is poured to make the castings. The only sand that has been found to give good results in molding is of natural origin, and consists of fine sand bonded by a small amount of clay. Numerous attempts have been made to grind silica and mix it with clay for the purpose, but this was expensive and the result was unsatisfactory, as the sand does not stand well in the molds. A microscopic examination of a good natural molding-sand shows the quartz grains to be angular, from the coarsest down to the finest that can be discerned. These angular grains do not pack as closely as rounded ones, and therefore the mass has a greater permeability to gases. These quartz grains show the characteristic fracture of silica that has been comminuted by crushing under pressure, rather than by attrition or abrasion. The molding-sand obtained in most of the Eastern States is found in the area of glacial drift, and is supposed to be of glacial origin. Some sand suitable for foundry-molds has been mined near Ione, in Amador county, California, but good sand of this description is scarce.

MINERAL OUTPUT of British Columbia during 1916 is officially valued at \$42,970,555; a record and an increase of \$13,523,047 compared with the previous year. Both lode and placer gold showed a decrease.

The Origin and Geo-Chemistry of Magnesite

By S. H. Dolbear

INTRODUCTION. Magnesite is usually defined as the normal carbonate of magnesia, composed, when pure, of magnesium oxide 47.6% and carbon di-oxide 52.4%. Mineralogically this definition is correct, but magnesite subjected to heat loses its carbon di-oxide, and the residual magnesium oxide is also designated as 'magnesite.' The use of the word has become too general to limit its application alone to the carbonate. Furthermore, the word 'magnesite' is not used generally in describing artificially prepared magnesium carbonate.

VEIN DEPOSITS. Magnesium forms with silica a long list of silicates. Very few of these occurring in nature are simple silicates of magnesium, for they usually contain iron, alumina, lime, and sometimes other elements in varying formulae, as for example hypersthene, diopside, and the more complex augites.

The ease with which magnesium silicates are broken down when brought in contact with carbonic acid and water has been demonstrated in the laboratory. In the case of the alteration of olivine the reaction is represented by the equation:

$$2\text{Mg}_2\text{SiO}_4 + 2\text{H}_2\text{O} + \text{CO}_2 = \text{H}_4\text{Mg}_3\text{Si}_2\text{O}_{10} + \text{MgCO}_3$$

and similarly in enstatite:

$$4\text{MgSiO}_3 + \text{H}_2\text{O} + \text{CO}_2 = \text{H}_2\text{Mg}_2(\text{SiO}_3)_4 + \text{MgCO}_3$$

In each case magnesite (MgCO_3) is one of the products, while it will be seen that the residual materials possess chemical formulae different from one another. This residual material is represented in nature principally by serpentine but sometimes by such substances as talc, and chlorite. Lack of space prevents a discussion of the chemical influences of carbonic acid on each of the many silicates, but the cases stated above may be taken as characteristic. It is noted that water plays an important part in these reactions, the residual material usually becoming hydrous. These reactions, however, appear to be incomplete and it is logical to conclude that all of the magnesium present in the original rock—olivine, enstatite, etc.—may be converted to magnesium carbonate if the conditions resulting in the incomplete change persist. Then reaction (1) below would be followed by reaction (2), the conversion of all magnesium present to MgCO_3 would be accomplished, while water and silica would be set free.

(1) $4\text{MgSiO}_3 + \text{H}_2\text{O} + \text{CO}_2 = \text{MgCO}_3 + \text{H}_2\text{Mg}_2(\text{SiO}_3)_4$

(2) $\text{H}_2\text{Mg}_2(\text{SiO}_3)_4 + 3\text{CO}_2 = 3\text{MgCO}_3 + \text{H}_2\text{O} + 4\text{SiO}_2$

This would then account for the free silica in magnesite deposits and justify the supposition that deposits in rocks that are greatly altered are more likely to contain high proportions of silica than those in less altered areas.

CARBONIC ACID. Several sources of carbonic acid are possible:

1. Atmospheric carbonic acid.
2. Organic—arising from oxidizing organic matter.
3. Occluded gases.
4. Deep deposits of calcium carbonate.

1. Atmospheric carbonic acid is that present in the atmosphere, which today contains normally about 3 parts by volume in 10,000. Heavy vegetation during the

VEIN OF MAGNESITE IN A CALIFORNIAN MINE.

Carbonaceous age leads us to believe that the atmosphere of that time contained a much greater proportion. While the magnesite deposits are of a later period, the fact remains that the diminution of CO_2 in the atmosphere was gradual, so that during the time magnesite was being formed this source was more important than now.

2. Organic carbonic acid need not be taken as an important factor. There is no evidence of abundant organic matter in the vicinity of magnesite deposits.

3. When heated to high temperatures in vacuum, rocks are made to yield astonishing quantities of uncombined gases, including carbonic acid. It cannot be contended that the presence of these is due to absorption, as free

hydrogen is also driven off, and the latter is not known to exist under normal conditions in the atmosphere. As the alteration of these rocks to magnesite and associated substances is dependent on the presence of water, it is not probable that these occluded gases have any immediate influence unless other agencies—such as heat—set them free.

4. Calcium carbonate as a source of CO_2 in magnesite has not been hitherto suggested, but it seems worthy of consideration. There is some evidence, of an indirect character, that relatively deep-seated limestone deposits may exist in at least some of the magnesite localities. 'Gas pockets' are not at all uncommon in magnesite mines. Sulphide minerals, such as pyrite, are found disseminated through the associated rocks. These sulphides when undergoing oxidation would acidulate descending solutions, which might themselves react on the magnesium-silicate rocks were they to reach them under favorable conditions as to heat and pressure. If, however, these acid solutions be brought in contact with the calcium carbonate of an underlying series, CO_2 would be liberated.

Masses of magnesium silicate intruding through limestone would cause a change in both. This might be represented by the formation of magnesium carbonate and a calcium silicate within the contact region.

DEPOSITION OF MAGNESITE. The presence of CO_2 in great excess would increase the solubility of MgCO_3 and this would be deposited when the solution yielded its excess CO_2 through freedom from pressure, cooling, evaporation, or because a part of the CO_2 would be required to form MgCO_3 with the magnesium-silicate rocks with which it would come in contact. Then we would have magnesite replacing the wall-rock of veins, and examples of this kind are quite common. It may be recognized either by the presence of serpentine 'horses' or by the gradation of magnesite into the wall-rock, usually without any distinct mark between the two.

We have then two types of deposit resulting from the alteration of magnesium silicates, the true vein deposit and that resulting from replacement. The latter would usually be irregular in form and might be designated as lenticular.

SEDIMENTARY DEPOSITS. Two of these have been reported in the United States; they are believed to have resulted from the contact of soluble magnesium salts with alkaline carbonates. The most common soluble magnesium compounds found in nature are the chloride and sulphate. The reaction would be represented by

Sodium carbonate is quite common in the desert alkaline basins and it is in these regions that the sedimentary deposits are found. The question, therefore, is not the source of the carbonate radical, as in the case of vein-type deposits, but the source of soluble magnesium compounds.

Sufficient space is not available for an exhaustive dis-

cussion of this subject. In the Pacific Coast region there are two examples of this type of deposit, one at Bissell, near Mojave, California, and another near St. Thomas, in Nevada. Data regarding magnesian rocks that might act as a source of magnesia in the latter locality are not available. The magnesian series in the Bissell area are represented by talc, actinolite, and similar alteration products of primary basic rocks. The presence of gypsum (CaSO_4) and sodium sulphate in this area suggests that the magnesium salt entering into the final reaction to form magnesite was magnesium sulphate.

The sulphuric acid radical undoubtedly had its origin in decomposing pyrite, but it is not at all certain that the alteration of magnesium-silicate rocks was due directly to contact with sulphuric or sulphurous acid in the circulating ground-water. Had this been the case the decomposition would probably have been more complete and the resulting solution would have contained much iron. Analysis of the Bissell ore does not disclose a large iron content. Four analyses show

Evidence points to alteration by carbonic acid and the subsequent action of sulphuric acid on magnesium carbonate in solution to form the more soluble magnesium sulphate. This was carried to the playa in solution and here brought into contact with alkaline carbonates, also in solution, as indicated by the reaction stated above.

Another point leading to the belief that magnesium sulphate rather than magnesium chloride was the salt involved, is the relatively small quantity of lime present. The agencies producing magnesium chloride would probably also have produced calcium chloride, the solubility of which is very high. In the case of sulphates, the calcium salt would be insoluble and a separation afforded from the magnesium sulphate. Analyses for CaO reveal: 4.25% ; 3.36% ; 1.56% ; trace.†

The recent discovery of dolomite adjacent the deposits of sedimentary magnesite at Bissell cannot be explained until further data regarding the occurrence are available. It will probably be found to have originated during a different geologic period and from a source not closely related to that of magnesite.

Deposits of sedimentary magnesite should be examined for soluble alkalines if intended for refractory use, because the presence of such alkalines in quantity would reduce the fusing-point of the material.

HYDRO-MAGNESITE. This is a magnesite having the composition $3\text{MgCO}_3 \cdot \text{Mg}(\text{OH})_2 + 3\text{H}_2\text{O}$.

It occurs both in sedimentary and vein deposits, and in the latter is probably a secondary product formed when magnesite has been re-dissolved and re-precipitated by chemical reactions such as are described in the foregoing paragraphs on sedimentary magnesite. It is usually associated only sparingly with magnesite in veins, although at Red Mountain in Stanislaus county, at Devil's Hole in Alameda county, and in British Columbia it is found separately in quantity.

*Analyses of J. S. Fairchild, U. S. Geological Survey.

Copper Consumers in the United States

After considerable investigation the *Boston News Bureau* has compiled the following:

	Monthly lb.	Per annum lb.
American Brass Co.....	25,000,000	300,000,000
Buffalo Brass Co.....	12,000,000	144,000,000
Chase Rolling Mills.....	12,000,000	144,000,000
National Conduit & Cable Co.....	10,000,000	120,000,000
Detroit Copper & Brass Co.....	8,000,000	96,000,000
Scoville Manufacturing Co.....	8,000,000	96,000,000
Roebbing Sons Co.....	6,000,000	72,000,000
Standard Underground Cable Co...	6,000,000	72,000,000
Bridgeport Brass Co.....	6,000,000	72,000,000
Rome Brass & Copper Co.....	6,000,000	72,000,000
American Electrical Works & Phil- lips Insulating	6,000,000	72,000,000
Waelark Manufacturing Co.....	4,000,000	48,000,000
Baltimore Copper Smelting & Roll- ing Co.	4,000,000	48,000,000
Seymour Mfg. Co.....	3,500,000	42,000,000
American Steel & Wire Co.....	2,500,000	30,000,000
Michigan Brass Co.....	2,000,000	24,000,000
Plume & Atwood.....	1,500,000	18,000,000
Bristol Brass Co.....	1,250,000	15,000,000
Baltimore Tube Works.....	1,000,000	12,000,000
Taunton-New Bedford Copper Co..	1,000,000	12,000,000
Randolph Clowse	1,000,000	12,000,000
C. G. Hussey Co.....	1,000,000	12,000,000
Stamford Rolling Mills	1,000,000	12,000,000
Hendricks Brothers	750,000	9,000,000
Miscellaneous	6,500,000	78,000,000
Total	136,000,000	1,632,000,000

From an obscure position the Buffalo Brass Co. has forged rapidly ahead to a position second only to the American Brass Co. in the amount of copper used.

Eolian Concentration of Mineral Salts

Desert basins frequently afford evidence of the former existence of lakes that at one time covered large areas. Usually these 'lakes' now are entirely dry. Their distinguishing feature is a level floor of hard sandy clay. Some of them become covered with a shallow sheet of water immediately after a heavy rain, but evaporation is rapid and they resume their dry state quickly. In such dry basins the minerals that once were held in solution have been precipitated after the water became saturated with them by continued evaporation. When this has happened such minerals may now be seen forming a snow-white crust on the surface, or they are found in a succession of deposits intercalated with layers of fine sandy clay that has been carried into the lake during successive floods. The principal mineral salts thus deposited are sodium and magnesium chlorides, calcium borate, borax, sodium and magnesium carbonates, sodium and magnesium sulphates, and calcium sulphate. There are other salts—notably those of potassium—but these

usually occur, if at all, in relatively small amounts and in few places. Borax, salt, and soda are the minerals of greatest commercial importance that have been obtained from such sources. There is an unusual deposition of mineral salts on the east side of the Rodriguez dry lake, on the Santa Fe railroad 20 miles south-east of Mojave, in Kern county. This lake covers nearly 60 square miles. No efflorescence of mineral salts shows on its surface, but, on what may be called its eastern shore, there is an accumulation of sodium and magnesium sulphate, with some carbonate. These salts are found in crusts or layers of coarsely crystallized mineral in little basins among the sand-dunes that line the shore for a long distance. Curiously, the sand-dunes are confined almost exclusively to this side of the lake, indicating the prevailing direction of the wind. As there is seldom any water standing, and as there is no efflorescence of minerals to be seen, the natural query is, what is the origin of the concentration of mineral salts on the east shore? A number of wells and bore-holes were sunk in the lake-bed to determine the character of the subterranean water, which was found a few feet below the surface. Analyses showed the presence of sulphates and carbonates of sodium and magnesium, but in minute quantity. The conclusion was reached that the crystallized minerals deposited in abundance among the sand-dunes must have originated from the surface of the lake, where they had formed repeatedly as a thin efflorescence, and that the minerals had been blown from the floor of the lake, when dry, upon the east shore together with the sand. There are several small springs in the vicinity—mere seepages—but these, apparently, have supplied sufficient moisture to dissolve and concentrate the salts in favorable places.

Gold From River-Bottoms

On the Ohinemuri river, 17 miles from Waihi and 8 miles from Karangahake, New Zealand, the Waihi-Paeroa Gold Extraction Co. continues to recover gold and silver from the tailing washed down that stream from the plants treating ore in the mining districts. This tailing is rather the accumulation of years than new material. It is dredged from the river-bottom, ground in tube-mills (22), cyanided by agitation in Pachuca tanks, and filtered by vacuum-filters. A recent yield was \$23,500 from 16,700 tons of tailing, equal to \$1.40 per ton. Since starting operation 653,700 tons has given bullion worth \$936,000. Dividends amount to \$60,000.

Flotation at Broken Hill

Owing to labor troubles early in 1916 the De Bavay process of the Amalgamated Zinc company operated at low capacity. In 20 weeks 91,438 tons of tailing was treated, yielding 25,669 tons of concentrate assaying 48.9% zinc, 5.8% lead, and 7.4 oz. silver; also 440 tons containing 58.6% lead, 9% zinc, and 48 oz. silver per ton. Treatment, royalty, and payment of tailing, etc., cost \$5.08 per ton.

RECENT PATENTS

1,204,554. TUBE-MILL. Johan S. Fasting, Frederiksberg, near Copenhagen, Denmark, assignor to F. L. Smidth & Co., New York, N. Y., a Corporation of New Jersey. Filed Apr. 28, 1915. Serial No. 24,437.

1. An improvement in the art of grinding in grinding mills which consists in producing in said mill a slowly rotating mass of grinding bodies and a material to be ground, applying closely related annularly arranged and extended frictional lifting ribs having surfaces extending in the direction of rotation to said mass while rotating and causing a free longitudinal feeding of said mass at points below the inner surface of said rotating mass.

1,202,219. ORE-SEPARATOR. Albert M. Plumb, Denver, Colo. Filed June 30, 1913. Serial No. 776,529.

1. In an ore jig, a separating chamber provided with means for maintaining at least two separate columns of material communicating at their lower ends and with discharge openings for each column, the relative heights of the discharge openings being such that the weights of the columns of material, when each extends to the level of its discharge opening, will be substantially proportional to their horizontal cross-sectional areas, means for agitating the material in the separating chamber and means whereby the material adjacent to the tailings discharge opening will be agitated to a greater degree than other portions of material in the same column.

1,205,326. ART OR METHOD OF TREATING SLIMES. David Cole, Tucson, Ariz. Filed Apr. 12, 1913. Serial No. 760,702.

1. The art of separating crystalloids from slimes which tend to become flocculent, which consists in diluting the slime mixture sufficiently to insure the existence of spaces between the flakes for the passage of the crystalloid particles, allowing said particles to settle through said spaces and removing said flakes while in suspension from the settling zone and prior to the precipitation of any substantial portion thereof.

2. The art of separating crystalloids from slimes which tend

to become flocculent, which consists in diluting the slime mixture sufficiently to insure the existence of spaces between the flakes for the passage of the crystalloid particles, holding said diluted mixture in a shallow depth or layer and allowing said particles to settle through said spaces, whereby interference by the flakes with the settling particles is minimized, and removing the flakes while in suspension from the settling zone and prior to the precipitation of any substantial portion thereof.

1,205,936. LEACHING ORES AND OTHER PRODUCTS. John Edward Rothwell and Hugh Blackie Lowden, Denver, Colo., assignors to Colorado Iron Works Company, Denver, Colorado, a Corporation of Maine. Filed June 3, 1912. Serial No. 701,282.

A method of continuous leaching consisting in actively agitating a mixture of solids and solvent in a suitable vessel, continuously withdrawing solids with a portion of the liquid directly from said vessel while it is undergoing such agitation and passing the same to a following vessel, and at the same time continuously passing a substantially clear solution directly from said first named vessel to a preceding vessel.

1,207,174. MILL-LINER. Frank E. Johnson, Salt Lake City, Utah, assignor to American Manganese Steel Company, Augusta, Me., a Corporation of Maine. Filed May 27, 1916. Serial No. 100,218.

1. A liner comprising lining plates, lifting bars interposed therebetween, said lifting bars formed with base sections and with wear sections, said lining plates and lifting bars completely housing base sections.

2. A mill liner comprising lining plates, lifting bars interposed therebetween, said lifting bars formed with base sections spaced from the edges of the adjacent lining plates, and wear sections, mounted upon said base sections, secured thereto and projecting to opposite sides thereof.

1,202,512. METHOD OF CONCENTRATING ORE BY FLOTATION. Gustaf Gröndal, Djursholm, Sweden, assignor to Beer, Sondheimer & Co., Frankfurt-on-the-Main, Germany. Filed Jan. 18, 1916. Serial No. 72,757.

1. The flotation method consisting in projecting a heated gaseous current having a selective agent diffused therein

against an opposed current or ore pulp, and collecting by flotation the particles thereby differentiated.

2. The method herein described of concentrating finely divided ore by means of oil flotation, said method consisting, essentially, in first distributing oil in a stream of heated gas under pressure and thereby atomizing the oil, then utilizing the flow of the gas-oil to commingle therewith a large quantity of another gas, and forcing the gas-oil mixture thus formed into a liquid against a counter-current of finely divided ore.

1,210,392. DECANTING APPARATUS. Julius H. Alpenfels, Denver, Colo. Filed Feb. 5, 1916. Serial No. 76,424.

1. In apparatus for settling solids out of liquid, a vat having an outlet for settling solids, a plurality of ports for the overflow of liquid rising out of the settling solids, a trough to receive liquid passing through said ports, and filters covering said ports.

2. In apparatus for settling solids out of liquid, a vat having an outlet for settling solids, a plurality of ports for the overflow of liquid rising out of the settling solids, a trough to receive liquid passing through said ports, and filters composed of screen-covered fabric, covering said ports.

1,208,249. METALLURGICAL FURNACE. Utley Wedge, Ardmore, Pa. Filed Nov. 21, 1914, Serial No. 873,246. Renewed Apr. 27, 1916. Serial No. 94,055.

1. The combination, in a metallurgical furnace, of a casing having a hearth with a treating chamber above the same, a shaft, an arm projecting therefrom into said treating chamber and open at its shaft end, a valve sliding across said open end of the arm but otherwise rigidly mounted, and means for imparting such sliding movement to said valve, said means being otherwise rigid.

1,210,880. PROCESS FOR SEPARATING PRECIOUS METALS FROM THEIR ORES. William Henry Aghan, Burke's Flat, Victoria, Australia. Filed Dec. 9, 1914. Serial No. 876,350.

1. In separating precious metals from their ores—subjecting such ores to the action of a bath containing a solution of water, cyanid of potassium, sulfuric acid, corrosive sublimate,

and common salt, in the approximate proportions described, other reagents capable of modifying the action on the bath being excluded.

1,206,960. RABBLE-ARM AND RABBLE FOR METALLURGICAL FURNACES. Utley Wedge, Ardmore, Pa. Filed Jan. 7, 1915, Serial No. 958. Renewed Apr. 27, 1916, Serial No. 94,056.

1. The combination, in a metallurgical furnace, of a central shaft, a sleeve carried thereby, a stub end structure carried by said sleeve and projecting into the furnace chamber, and an arm detachably mounted upon that portion of the stub end structure which projects into the furnace chamber.

2. The combination, in a metallurgical furnace, of a central shaft, a sleeve carried thereby, a stub end structure mounted in said sleeve, and projecting therefrom into the furnace chamber, said stub end structure being detachable from said sleeve, an arm detachably mounted upon that portion of the stub end structure which projects into the furnace chamber.

1,209,269. MAGNETIC SEPARATOR. Myron Dings and Robert A. Manegold, Milwaukee, Wis., assignors to Dings Electro-Magnetic Separator Co., Milwaukee, Wis., a Corporation of Wisconsin. Filed Aug. 11, 1911. Serial No. 643,504.

1. The combination with a set of vertically disposed electromagnetic coils having polar projections of opposite polarity at their upper ends, a horizontally rotating solid disk of magnetizable material having its outer portions located above said pole pieces and adapted to form a straight path for magnetic lines of force extending directly across from the space above one pole piece to the space above the other, means for rotating said disk and having means for feeding material containing magnetite through the gap between the pole pieces and said disk, said conveying means comprising a thin support for the material having but one thickness in the supporting member, whereby the dimensions of the air gaps are reduced to a minimum and a magnetic separator of high intensity produced in which the solid rotating disk forms an induced magnet rotating in close proximity to the pole pieces.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

SITUATION IN THE ZINC REGION DURING JANUARY.

Bad weather throughout January seriously interfered with mining and deliveries to smelters. There were other causes contributing to a lower output and restriction of development, yet these drawbacks failed to prevent a fairly good showing. Prices for zinc-blende at the beginning of the month held at \$75 per ton for 60% ore, premium grades realizing \$5 higher. No competition developed, and several smelter agents failed to put in an appearance, indicating that lower markets were expected. In the second week there was a drop to \$72.50, with the range on medium and second-grade ores down to \$70. Demand for lower-grade ore fell off, and mine-run product began to accumulate with most of the independent operating companies. A marked change for the better then manifested itself in the spelter markets, and almost without warning the third week found zinc ore advanced almost over one night \$11 per ton, the price being \$82.50 on standard 60% concentrate, with premium grades about \$5 higher. This highly desirable condition prevailed until about the end of the month, when the quotation was \$85, with premium grades at \$90, when a war scare literally swept away all supporting props and a feeling akin to panic seemed to grip the market. Some of the refiners in the field, who had calculated that prices would take a sharp upward turn, had intentionally withdrawn considerable quantities of separator product, all of which was promptly marketed when prices seemed more nearly to their liking. The close of the month found no high-grade zinc product in bins, and sellers were pleased that advantage had been taken of the brief interval of higher offerings that immediately preceded the break between the United States and Germany. Many leading operators, personally interviewed regarding the situation in the field at the return of better prices, complained that operating conditions were distracting in spite of better prices for ore. Wages are the highest ever known, a genuine scarcity of labor, especially skilled classes of labor, is admitted, and supplies are in many cases from 40 to 60% higher than a year ago. The general manager of one of the largest producing groups of zinc mines here declared that lower metal and ore markets must necessarily mean a reduction in wages throughout the region. No relief is anticipated in the cost of supplies, but it will be practically impossible for producers to continue with the present wage-scale in force. On the other hand miners declare that the higher cost of living makes it imperative that good wages continue, and the outcome of the situation arising from the sea warfare is being awaited with considerable anxiety by all parties connected with zinc mining.

Lead ore producers were favored during January like the zinc miners. Prices commenced at under \$90 per ton. Advances in the price of pig-lead, at one time up to 8c. per pound, raised prices for ore, and producers who had been holding their product sold a little ore at \$100 per ton. It was intimated in well-informed quarters that prices would even exceed this figure, and the greater part of the ore mined during the month was carried over in bins in expectation of just such developments.

Continued high prices for sulphuric acid kept up the better offerings that prevailed for iron pyrite, but shipments for January were lighter than usual, about half. Refineries carried over a considerable quantity of fine, recovered in mag-

netic zinc-ore separation. This was partly due however to the improved prices for zinc-blende.

Producers of carbonate of zinc ore (locally termed 'dry-bone') lost the only outside buying interest represented in the field, and such ore as was offered for sale cleared through the old established channels afforded by the Mineral Point Zinc Co. The nature of the mill-feed precludes free handling of this grade of zinc ore during extremely cold weather such as has prevailed in this field, and production has been light.

Up to and including January 27 ore deliveries totaled 21,614 tons of blende, 215 tons of lead, and 1882 tons of pyrite.

EL PASO, TEXAS

IMPROVEMENTS AT THE A. S. & R. SMELTER.

The American Smelting & Refining Co. spent approximately \$500,000 during 1916 in remodeling and improving its smelter here. It is officially stated that an additional \$500,000 will be spent in enlarging the plant during the current year. The copper department has been greatly enlarged. A new 400-ft. stack is one of the latest improvements being constructed. A mechanical oil-handling system will be installed during 1917. Production of blister copper has given way to a method whereby copper bars are made ready for electrolytic treatment at Eastern refineries, instead of having to be re-melted. Two anode furnaces and a casting-machine make slabs weighing 600 lb., instead of the 300-lb. blocks. These are served by large electric cranes, carrying the molten metal from two new converters. The old steam tramway has been dispensed with in the copper department, and is used only for moving slag and serving the lead-furnaces. The 300-ft. reinforced-concrete stack for the copper plant was put in commission late in 1916. The old style reverberatory-furnaces that did service for several years have been displaced by the new anode furnaces. To carry off gases from the roasting-plant a brick stack, 30 ft. diam. at the top and much wider at the bottom, is being built to a height of 400 ft. Improved mechanical ore-feeders for the furnaces are to be installed. Additions to the machine-shops have been made. While the expansion of the smelter has been going on to take care of the copper business, the six lead-silver furnaces have been constantly in blast. At the beginning of operations by the company, which is known as the Kansas City Consolidated Smelting Works, lead-silver bullion was its only product. Revival of copper mining in New Mexico in the last few years demanded that the works be added to in order that the immense tonnage of copper ores be treated. The beginning of the enlargement dates from the contract made with the Chino Copper Co., which ships its concentrate from its New Mexico mine to El Paso. The converter-house, a steel structure, contains two Pierce-Smith converters, two anode furnaces, a casting-machine, and cranes. The roasting-plant consists of eight Wedge furnaces, each of 200-ton daily capacity. Oil is used for fuel. Coke from the Colorado and New Mexico coal-fields is supplied for reducing the lead-silver ores. Slag is moved by steam tramway from the furnaces to the dumps on the north side of the smelter hill. Electric power for motors and lights is generated by Corliss engines. A good-size lake on the top of the hill, replenished by a pumping-system from the Rio Grande, supplies water to the boilers. Normally the smelter employs between 1400 and 1600 men, but during the past few months the force has been increased to nearly 1800. The monthly payroll is over \$100,000.

MELBOURNE, AUSTRALIA

A REVIEW OF THE AUSTRALIAN MINING INDUSTRY

Australian mine operators have had an eventful year. Shortly after the War began, the Prime Minister, W. M. Hughes, realized how completely the metal trade of the Commonwealth was in the hands of German firms like Mertons, Aaron Hirsch, Beer-Sondheimer, and others, and started transferring this control to British concerns. At first he met with some open opposition and a lot of passive resistance, but he showed that the power vested in the Federal Government under the War Precautions Act was not to be flouted. Some of the old Australian and London friends and company partners in many a mining and share deal of the German

ing, and it is expressly stipulated that they must not be members of any stock-exchange. For the most part the members are either the directors of the large base-metal mining companies or firms of British origin that had a pre-War connection with the metal trade. The peculiar part of this organization is that while members of the stock-exchange were taboo, their closest associates and actual partners in share transactions or in the control of mines may belong to the organization. It has now been in existence for a year or so, and as all the metals produced in Australia must pass through its hands for sale, the members are a highly satisfied body of men. No wonder when Mr. Hughes returned from America they deemed him the subject of special laudation, though a year before, more than one of the members would have torn

THE 1060-MILE RAILROAD ACROSS THE CONTINENT WILL BE FINISHED AT AN EARLY DATE.

metal firms kicked, but among their ranks were two or three men of discernment. These saw that if the War continued there must be an adjustment of trade relationship. They perceived further, that, with a Labor government in office in Australia, there was every risk that if the situation Mr. Hughes was creating was not skilfully turned, there would be the possibility of a socialist domination being established. Then the business that had been built up during the previous decade with such skill and profit would be dispersed. This meant interference with large interests in the big group of Broken Hill silver mines and regulating—in the interest of the State—the expanding copper trade of north Queensland and southern Australia. If Mr. Hughes had selected as his instrument to investigate, and advise, a man at all tinged with his own party ideals, a State organization would have been ensured. As it was, he impressed a man of fortune and of probity as his adviser—one skilled in metallurgy, possessing doggedness of disposition and ability. Whether he suggested the Metals Exchange or not is not at all clear. If he did, the Prime Minister fell in with the idea most readily. This organization is now established to deal with the metal output of Australia. Its members have to show a good financial stand-

him to pieces for even daring to suggest the control of the metal trade through such an institution as the Metals Exchange. Whether this Exchange will last after the War will depend on more than one factor. If the Allies win, and carry out an effective trade combination, which will involve the exclusion of subjects of the Central Powers or neutrals from participation in the trade of the British dependencies, then it may continue. Or, if the Commonwealth government decides that it will place an export duty or restrict the export of metals to only Allied nations, the organization may persist. But some big international problems may have to be settled if action of this kind be taken. One point that will have to be determined will be whether the patriotic impulses of the members comprising the Exchange will be sufficiently shown for those who were not pro-British before the War to reject business overtures that may be extended to them. Of course, if the State had taken the trade into its hands then it would have been able to act as it liked, appoint its own agents, and nominate their business. As it has not done that, the future is full of business intricacies.

Out of the same series of events came the Zinc Producers' Association. This is another child of Mr. Hughes, and of his

adviser. Its birth was not without travail; for the Prime Minister or his deputy, the Attorney-General, had to compel the co-operation of the Broken Hill Proprietary and the Mt. Lyell companies, as these apparently had decided at the last moment to keep out of the organization. No one quite knows what were the motives, but had they been stubborn, it is almost certain that Mr. Hughes's arrangement with the British government to purchase a quantity of the zinc concentrate or spelter would have been checked. Anyway, the companies fell into line and the Zinc Producers' Association stands as another creation of the War aimed directly at wresting from the Germans their trade in the zinc products of Australia. It must not be supposed that the two companies just named were pro-German. They would have been ready to give any guarantee to trade only with British firms as refiners. That being so, it can be assumed that what they desired was to retain the handling of their own products. However, these have to go to the Zinc Producers' Association. This body, like the Broken Hill Associated Smelters Co., is described as being a co-operative body; that is, the profits of all the business transacted are to be divided among the companies or mines that subscribe or are affiliated with the organization. Great care has been taken to make these controlling concerns proprietary companies, so that their balance-sheets will not reach the eye of the public, or, for the matter of that, be disclosed to the shareholders of the co-operating companies. They may pass to their directors, but that is the most. In consequence, no one outside can know how costs are going, what are the management charges, or the fees paid to directors. To the lay mind the Zinc Producers' Association, the Metals Exchange, and the Broken Hill Associated Smelters appear to be a fusion of the interests at present commanding the output of the leading base-metal mines of Australia. How they would stand in the event of new mineral discoveries will rest on the power to control exports and internal trade under peace conditions.

In the meantime great importance attaches to the experiments set in train to utilize the cheap water-power of Tasmania for the manufacture of zinc electrolytically. To assist in the solution of the problem, the Amalgamated Zinc (De Bavay) Co. sent H. W. Gepp, its general manager to the United States to investigate. That official has returned, and has brought with him sundry experts. A company with a capital of £100,000 has been formed to carry on the initial experimental work near Hobart, under the most advantageous terms, so far as cheapness of power goes. It is expected that this venture will include the Broken Hill South, the North Broken Hill, the Amalgamated Zinc, and perhaps the Zinc Corporation, belonging to the Hoover-Govett group of London, as all these silver-lead-zinc interests have for a considerable time past co-operated in a number of enterprises. The Broken Hill Proprietary Co. has almost exhausted its mine at Broken Hill, so it is not the important factor in the zinc market it once was. The other big producer of the future is sure to be the Mt. Read & Rosebery Co., formed a month or two since to take over the zinc-lead silver mines at Rosebery in Tasmania. These comprise the Hercules, Tasmania Copper, and Primrose mines. Their reserves have been estimated by one of the members of the State Geological staff as follows:

	Blocked out, tons	Probable, tons	Total, tons
Hercules	273,000	391,000	664,000
Tasmanian Copper	185,000	341,000	526,000
Primrose	33,500	49,000	82,500
Total	491,500	781,000	1,272,500

The average assay of 263,000 tons mined in these mines to date is 29.79% zinc, 8.89% lead, 12.16 oz. silver, and 0.17 oz. gold per ton. Mr. Hills considers that the ore reserves may be accepted as agreeing in average composition with that

already broken. The Mt. Lyell company has done a good deal of boring since it got possession of the mines, and has made a substantial addition to the reserves. Further, it has sent a consignment of ore to Broken Hill to ascertain if it is amenable to flotation treatment. These experiments have been most encouraging, and confirm the work done by the staff of Messrs. Bewick, Moreing & Co. under the guidance of Mr. G. C. Klug when the Tasmanian Copper Co.'s lease was under offer to a strong European-Australian syndicate before the War started. It does not appear as if the Mt. Lyell company will get its power from the Great Lake scheme of the Tasmanian company, on which the Broken Hill group relies, but will seek to utilize some of the streams and lakes on the west coast of Tasmania to generate power for itself, as it is already doing from Lake Margaret for its mine and smelter. Estimates show that it should be able to obtain power at a low figure. No doubt now that the Mt. Lyell's properties are in order and the Tasmanian government has given it a most favorable enabling statute, it will rapidly develop its scheme for handling the resources of the important district that it will control through the Mt. Read & Rosebery Co. One step is sure to be taken, that is, to secure the services of a man highly qualified in the electrolytic treatment of such ores as those of the Rosebery field, and the expectation is that he will come from the Anaconda staff at Butte.

So far as copper mining goes, little need be said. The only district where any development of importance is occurring is Cloncurry, in Queensland. There the Hampden company has been proving the existence of fair reserves of pyritic ore beneath the rich masses of copper glance in the upper levels. As a set-off, however, the Duchess mine below the 700-ft. level is not encouraging. This leaves the company to rely on its Trekalona and Pindora properties to fill the gap. The ore of the latter group is highly silicious, and concentration is to be by flotation. The first unit is at work, but results are not known. Then the London and Paris, owned by the Mt. Elliott company is developing a large group of mines, both on its own behalf and for a subsidiary company. The most promising results have been from the Dobbyn near Mt. Cuthbert, while the well-known Mt. Oxide mine is also being steadily developed. It, however, is too far off to figure as a factor until transportation facilities are improved. Among the old-established mines the Great Cobar in New South Wales is unable to show satisfactory development. This also is the position of Mt. Morgan, whose pre-War estimates had to be greatly revised. Wallaroo & Moonta in South Australia plod along, proving the soundness of the adage that a good mine is difficult to kill. Progress at the Mt. Lyell group proper has been satisfactory, that is to say, that developments have more than maintained ore reserves, which are equal to over eight years' life at the present capacity of the smelters. From time to time reports come to hand of discoveries of new copper deposits in northern Australia, outside of Queensland, but none of these have materialized into anything important. What has been done at the instance of the Federal government is the formation of a company to turn to account the supply of raw metal so that Australia shall engage in the manufacture of articles in which copper is the leading element. British capital is interested in this concern.

Evidence is not wanting that the tin resources of the country are being steadily depleted. At the Mt. Bischoff mine in Tasmania the main deposits are greatly reduced, and it is inevitable that the company will have to rely more and more on the tin it can extract from the alluvial at the foot of the mountain, and any new shoots it may succeed in opening on its north side. So far as alluvial tin goes, north-eastern Tasmania is the main source of supply; but here, too, resources are shrinking. The same is happening in northern Queensland and in New South Wales. A gleam of hope comes from the Northern Territory, where some discoveries have been made, but so far the yields have lacked persistency. This

also is the case in Western Australia. Still, both of those States have such immense areas of undeveloped and unprospected territories that there is always hope of a lucky find. Diligent search is being made for tin, as it is considered that prices are at their lowest. The high prices for wolfram and molybdenum is stimulating the extraction of these metals, the output of which is under the control of the Federal government for War purposes. The other branch of the industry is gold mining. Unfortunately not a single development of importance has taken place since the Edna May group of mines was opened in Western Australia. Kalgoorlie is drawing on reserves rapidly, all the Queensland centres are much on the down-grade, and in Victoria and New South Wales the position is deplorable. Arising out of this condition of affairs one of the ablest among Victorian junior mining men, Mr. E. A. Dyason, has evolved a scheme for consolidating a group of Bendigo mines on the main central line of 'saddle' formations into one company. The area to be controlled is 1 by 5 miles. The only objection that can be offered to this consolidation is that labor conditions may not be fulfilled to the extent that is necessary in the interests of the field. The State no doubt will attend to this matter before it grants any such a consolidation as is suggested. What Mr. Dyason aims at is to secure cheaper working, more effective control, the centralizing of surface equipment, and the introduction of more scientific mining methods.

Taken as a whole, the outlook for mining in Australia is the reverse of encouraging. Only one field of importance is emerging from the lot, namely: the Mt. Read and Rosebery in Tasmania, controlled by the Mt. Lyell company. Prospecting is almost a lost avocation, on account of the general state of the industry for the last decade. The huge expenditures on public utilities by State governments have led to the diversion of men from mining to less hazardous occupations. The outbreak of War caused the staffs at a number of mines to be reduced, owing to the volunteering for military service. There also has been restriction of credit and of the promotion of companies. Above everything, however, has been the militant attitude of the labor-unions. These have demanded, and been supported in their demand, by the Federal Arbitration Court, for increases in wages of from 25 to 50% on pre-War rates. With the grade of ore decreasing as depth is attained, it is only the base-metal side of the industry that can sustain such a burden. In its case the high price of metals enables the mines to bear the extra charge and make large profits. What will happen after the War nobody knows. It looks as if the gold output of the world is decreasing everywhere. If that be so, great economic issues are involved, amid which gold mining will not suffer. The increase in the world's yield of gold put up the price of commodities. A decrease will have the reverse effect, to come on top of the confusion occasioned by an adjustment of the national finances after the War. There may have to be a marking-down in the price of lead, copper, and other metals, because of the declining supply of gold. Accepting this deduction as correct, and recognizing that the borrowing policy of Australia must be greatly curtailed because of the smaller supply of capital available in London, there will be a huge reduction in public expenditure in Australia. [The total debt of Australia is £490,000,000.—EDITOR.] This will throw out of employment an army of workers. It is "a guinea to a gooseberry" that many of these will return to mining. They will search for gold, silver, lead, and copper. So, while economic problems may be disturbing to the politician and to the theorists who created the Arbitration Court, the net result of hard times may be to give Australia new gold or base-metal mines, owing to the forcing of men into prospecting the distant parts of its vast unexplored territory.

The Zinc Corporation in December treated 16,870 tons of zinc talling by flotation, and 14,211 tons of lead ore by concentration, yielding 4065 tons zinc and 3372 tons lead concentrates.

LEADVILLE, COLORADO

SILVER DISCOVERIES.—DOWN TOWN AND OTHER AREAS.

Several new and important discoveries of ore made recently have given added impetus to development in this district, especially in the outlying sections away from the central area that has been fairly well prospected. In the St. Kevin section the Griffin property is the scene of the greatest strike that has been made here for many years. The cutting of a new vein several weeks ago was looked on as important, but it was not thought to be of such unusual value as development has proved. The vein, where opened, was 8 ft. wide, and assayed \$75 per ton in silver. Driving on the ore-shoot has continued for over 200 ft., and several raises were driven a height of 275 ft. without reaching the top of the shoot. The value of the ore has increased remarkably, the average now being shipped carrying 160 oz. of silver. Bunches of high-grade ore have also been found in the vein, which appears to be the most persistent and richest discovered in the area. Production is 50 tons daily, and as soon as facilities for extracting a larger output are complete this quantity will be increased. New bunk-houses and an assay-office are under construction. The property is about five miles west of Leadville, and two miles from the nearest railroad siding.—A discovery has been made in the Dinero property on Sugar Loaf. Lessees have opened a small vein assaying as high as 531 oz. of silver per ton, while the lowest is 35 oz. The shoot has been opened for several hundred feet. The weekly output is 40 tons.—Development of the new vein opened in the Bartlett mine on Sugar Loaf indicates that the discovery rivals that at the Dinero in value, while the size of the vein is several times as large. The installation of an electric hoist at the collar of the interior shaft is now in progress. As soon as this is done mining will be undertaken on a larger scale.

The discovery of high-grade carbonate of zinc in the Down Town mines is a recent event of importance. A large body of 30% ore has been opened and regular shipments are being made. One hundred tons of iron-manganese ore is being extracted in addition to the zinc, and it is stated that if railroad cars could be secured the property would produce 200 tons.—James Daniels, well known here, has organized a new company and secured a sub-lease from the Down Town Mines Co. on the Grey Eagle, Crown Point, and Wildcat claims, east of the Penrose on Carbonate hill. Large bodies of high-grade silver-bearing iron and iron-manganese are known to exist in the Grey Eagle. The property is famous in the early history of the district as a heavy producer of high-grade silver and lead carbonate ores. It has been idle for over 20 years.

Unwatering of the Greenback in Graham park is completed, and station pumps installed at the bottom and 900-ft. levels are handling the water. The shaft, 1350 ft. deep, is the deepest in the district and is in the centre of one of the richest ore-zones. When this mine was closed several years ago on account of water it was said that there was a large quantity of ore blocked out in it. Exploration is now to be started under P. Mulrooney; it is expected ore will soon be shipped.

The La Plata property on Rock hill, which was recently drained by W. E. Bowden and others, is the scene of another new discovery, an extensive body of zinc carbonate being cut on the 500-ft. level. Development shows promising indications. A great deal of the ore is low grade and is shipped to the Western Zinc Oxide Co.'s plant here. Higher grade material is being shipped to zinc smelters outside of the State.

The old A. Y. & Minnie mine in California gulch is being operated by lessees, who are extracting a large tonnage of low-grade zinc carbonate. A contract for 3000 tons has been closed with the Western Zinc Oxide Co.

The Mt. Champion mine in the Lackawanna district continues to produce steadily high-grade gold ore. The mill has been closed for the winter, but it is stated that the plant will be enlarged during the spring and summer.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

In the annual report of the Board of Road Commissioners for Alaska it is stated that since 1905 the sum of \$3,390,123 has been spent on roads in the Territory. These include 920 miles of wagon-roads, 629 miles of winter-sled roads, and 2210 miles of trail. These cost respectively \$3144, \$345, and \$106 per mile. The wagon-roads are good for all the year heavy traffic. Over 250 motor-cars and trucks are used on the roads, including a regular mail and passenger service between Valdez and Fairbanks. Details of the past year's work is given in the report.

CHICHAGOF. The Sea Level Mining Co., operated by Fleming brothers on the west coast of this island, are developing a deposit of high-grade copper-nickel ore.

JUNEAU. December returns of the mines on Douglas island are as follows: Alaska Mexican—\$18,284 from 11,739 tons of ore, giving a profit of \$4026, including sundry revenue; Alaska Treadwell—\$53,041 from 24,843 tons, and \$23,058 profit; and Alaska United—\$86,375 from 43,974 tons, resulting in a loss of \$41,096. Diamond-drilling from the 2300-ft. level of the 700-Foot Claim gave the following: No. 3, for 22 ft. averaged 29c. per ton; No. 4 for 550 ft., \$1.65; and No. 5 for 22 ft., \$1.29.

ARIZONA

KINGMAN. In the Maynard district, east slope of Wallapai mountains, 20 miles south-east from Kingman, the Telluride Chief Mining Co. of Los Angeles has been developing and equipping its mine for 11 months. The company has opened a large tonnage of high-grade molybdenite ore, which with adequate milling plant will place the property in the front ranks of molybdenum producers. For this purpose an issue of treasury shares is to be made.

MIAMI. During January the Inspiration Consolidated mined 516,000 tons of ore, while the mill treated 523,000 tons. The company is making experiments in leaching the oxide ore.

The International smelter is to be enlarged by another reverberatory furnace and accessories.

OATMAN. The manager of the Gold Ore Mining Co., A. C. Werden, announces that he will send samples of ore for flotation tests to the Minerals Separation's San Francisco laboratory. If results are good the company may construct a flotation instead of cyanide plant. Oatman ores are ideal for cyaniding. As a rule the gold is fine, and the ore is crushed to 200-mesh, giving 96% recovery. Flotation, however, is less costly for installation and operation. With cyanide selling at 75c. per pound, and the supply limited, operators are inclined to investigate the merits of flotation.

The Big Jim shaft has passed the 600-ft. point and will have the sump completed and a station cut by the end of the week. Cross-cutting will be started and the vein opened at 90 ft. from the shaft. The cross-cut will be extended through the vein, and drifts driven east and west to the end of the ore-shoot. The 600-ft. level is considered likely to disclose some streaks of rich ore. As soon as the ore on this level is sufficiently developed to permit of sampling, mill tests will be made. The company contemplates the construction of a 400-ton mill.

A choice piece of ground adjoining the Tom Reed on the east, west, and south, and thought to cover the extension of the Tom Reed-Grey Eagle vein system, is to be vigorously de-

veloped by the Red Lion Mining Co. The shaft has been sunk 40 ft., a head-frame erected, and a hoist purchased.

The Gold Road Bonanza is driving on the vein, which was cut at 506 ft. in the shaft, at the 550-ft. level. At 525 ft. the vein left the shaft. An average of 60 samples taken between the 506 and 525-ft. points was \$30 per ton. The width of the ore-shoot increased from 18 to 36 inches.

The cross-cut tunnel at the Crescent is being driven for the main Crescent vein. The face is in andesite cut by stringers of calcite, indicating proximity to the vein. Cross-cutting continues in vein-matter on the 400-ft. level at the Adams. The cross-cut has been in vein-matter for 75 feet.

At the old Moss mine the Santa Gertrudis Corporation, Ltd., is down 500 ft. in the second diamond-drill hole at an angle of 60°. Reliable, but unofficial information, is that the first drill-hole cut a 12 ft. vein at 500 ft. The Moss produced \$240,000 from a shallow hole where a fault cut the vein 50 years ago. Subsequent work through a cross-cut tunnel failed to open the vein at depth.

CALIFORNIA

AMADOR CITY. On February 6 two miners were killed in a runaway skip in the Treasure mine. Negligence is charged one of the engine-men, as when the hoist brakes were thrown off, the clutch was out of gear, allowing the skip to break away.

CLOVERDALE. The Culver Bear company is employing 40 men at its quicksilver mine. A 5-ton furnace is in operation, but a 25-ton unit is nearly ready to start treating cinnabar.

COPPEROPOLIS. The Calaveras Copper Co., S. M. Levy in charge, is to construct a railway from its mine to Milton, the present nearest terminus.

GRASS VALLEY. At the Champion mine flotation tests are to be made on tailing in Deer Creek.

The Matteson ranch of 440 acres has been sold by J. J. Keeney to the Brunswick Consolidated for \$60 per acre. Part of the land is to be used for tailing storage.

MARYSVILLE. Some of the supervisors of Yuba county are protesting against the application of F. R. Ritchie, who desires to mine by hydraulicking at Howland flat, Sierra county, and impound the debris behind the concrete dam constructed across Slate creek, a tributary of the Yuba river. W. J. Mellon and W. J. Forbes, supervisors representing the mining industry in the county, disputed Supervisor Hyde's contentions.

(Special Correspondence.)—The McAlpine Mines Co. has acquired five additional claims which will be operated in conjunction with its original holdings, known as the McAlpine mine. The properties are situated near the Tuolumne-Mariposa boundary line.

The Black Oak company has made another rich discovery. The new orebody was found close to the line of the Live Oak claim, on the 1300-ft. level. The ore is of the same general character and appearance as that of the orebodies which made the mine famous during recent years.

Work has commenced at the Rawhide No. 2, recently acquired by H. H. Stambaugh and R. C. Steese. Buildings, head-frame, and other surface improvements are under way. J. Packard, until lately holding a position at the old Rawhide mine, has been appointed superintendent.

A claim that gives promise of becoming one of the great mines of Tuolumne county is situated on Shipley flat, two

miles from Chinese. It is being developed by Rowe and Packard. At a depth of 30 ft. the vein is 4 ft. wide, and particles of gold can be seen in almost every piece of rock broken. It is said the ore will probably yield \$200 per ton. Placer gold to the amount of at least \$1,000,000 was taken out of the immediate surroundings during the early days.

Development in the Basin mine, near Columbia, has been retarded by a sudden heavy inflow of water encountered while driving a drift toward one of the underground gravel-channels in the property.

Sonora, February 3.

(Special Correspondence.)—The main shaft at the Old Eureka mine has been unwatered to a point 50 ft. below the 1600-ft. level, and will soon be dry. Shaft work is using 50,000 ft. of lumber monthly. The new head-frame has been completed, sheaves put in place, and ore-bins built. The structure rises 110 ft. from the ground, but the height will apparently be decreased 32 ft. when the platform is built at the top of the concrete piers and the ground filled in around the collar of the shaft, this platform to be on a level with the engine foundation. The new hoist can be started as soon as motors arrive and are installed.

The Central Eureka is increasing the depth of its shaft 50 ft. below the point where the shaft cut ore. Some ore showing free gold is being extracted from stopes above the 2825-ft. level.

The California Clay Corporation, recently organized, has secured a 50-year lease on 30,000 acres in the Arroyo Seco grant from the Ione Coal & Iron Co., and will build a \$65,000 factory near the Southern Pacific station at Ione for the manufacture of fire-brick and other clay material. The plant is to have a capacity of 3,000,000 bricks annually and a yearly pay-roll of \$30,000. The clay deposits at Ione are of great extent, and certain desirable elements for the manufacture of fire-brick equal to the best on the market. The new company will make a bid for supplying the United States navy, which uses each year 1,000,000 fire-brick on the Pacific Coast. Officials are: George C. Hallerton, San Francisco manager for the Pacific Gas & Electric Co., president; Arthur S. Cunningham of Ione, vice-president and general manager; Jas. R. Keith of San Francisco, secretary; and E. V. McGinto of San Francisco, treasurer.

The question of the State's title to the Royal Consolidated property at Hodson, Calaveras county, is to be decided among other points by Judge Shields of the Superior Court. The property was taken over by the State for unpaid taxes, but the defendants allege that the State's title is faulty. Operations were resumed at the mines and ore extracted since the State acquired title, and the State is suing for the possession of the ore for an accounting.

Sutter Creek, February 11.

COLORADO

CENTRAL CITY. The American Smelting & Refining Co. issued a new schedule last week, applying to Clear Creek, Gilpin, and Boulder counties, in which the treatment charges for all classes of ores have been reduced 50c. per ton. The W. J. Chamberlain Ore Co., having sampling works at Black Hawk, Idaho Springs, Georgetown, and Boulder, also issued new schedules of rates, similar to those given of the smelter. In comparing the new rates with those adopted by the Argo mill at the mouth of the Newhouse tunnel at Idaho Springs, it is found that they are almost the same as charged by the Argo plant.

CRIPPLE CREEK. Gold output of the district during January was \$1,169,188 from 74,706 tons of ore. Dividends totaled \$342,941. Excessive cold weather curtailed production of several small mines.

The Roosevelt drainage-tunnel was advanced 160 ft. in 24 shifts. The face is now in the Phoenix claim of the Ramona

company. The flow of water is 8000 gal. per minute. The Cripple Creek Deep Drainage Co. has decided to continue the tunnel to the Portland mine, as the Vindicator company requires all the water from its mine for the mill.

During 1916 the Isabella Mines produced 19,377 tons of ore worth \$412,962, of which lessees (30 sets) mined 16,573 tons valued at \$258,688. The company's profit from all sources was \$66,663. A dividend, the first, of 1% was paid. Development covered 18,587 ft., an increase of 1298 ft. The most important result was the discovery of rich ore on the bottom level of the Lee shaft. An ore-house, costing \$12,000, was erected. The mill was operated since October on ore assaying \$3 per ton. The recovery from 1500 to 2000 tons monthly is 70%.

Published in *The Electric Journal* for December 1916, W. N. Clark of the Arkansas Railway, Light & Power Co. discusses electricity applied to metal mining. Service to Cripple Creek was begun in 1898. Lighting at that time cost 20c. per kw.-hr. Only small motors were used at first, with comparatively high rates. Storms interrupted the supply of power in the winter, also damaging transformers, meters, and motors. Four central stations competed with one another for business. The aluminum cell-arresters next enabled electric companies to give reliable service, air-compressors, mills, and other large consumers being connected up. In 1911 the Arkansas company took over most of the plants, and now operates three in parallel—one at Pueblo, one at Canon City, (both steam), and one hydro-electric near Victor. The load for the lot is heavy, Cripple Creek and coal mines at Canon City using 16,000 hp. The motors drive a variety of machines. There are no large electric hoists, the biggest being 200 hp. Storage-battery locos are used in the Portland mine.

GEORGETOWN. The Imperial mill, operated by Campbell & Co. has received two ball-mills, a 6-cell M. S. flotation machine, a 36-in. Akins classifier, a 3 by 4½-ft. Oliver filter, and a 60-hp. motor. The plant is being reconstructed to embody flotation.

LEADVILLE. In the Down Town property (Penrose shaft) a considerable quantity of zinc carbonate is being opened. Shipments of iron and manganese ore continue to be made.

The old Grey Eagle mine on Carbonate hill, near the Down Town mines, is to be re-opened by lessees in charge of Joseph Daniels. Equipment is being erected, and re-timbering of the shaft started.

SILVERTON. This district shipped 201 cars of ore and concentrate during January, a record for that month.

TELLURIDE. During January this district shipped 110 cars of ore and concentrate, as follows: Inama-Periono lease, 1; Liberty Bell, 13; Smuggler-Union, 36; and Tomboy, 60 cars. The new flotation annex at the Smuggler plant is nearly finished.

IDAHO

If the bill passes the State Legislature a bureau of mines and geology will be created for this State, to act in conjunction with the State University.

In the *General Electric Review* for February, Ben Olsen discusses the application of electricity to mining in the Coeur d'Alene. The region, until recently, was served exclusively by the Washington Water Power Co. Now the Montana Power Co. supplies some current. In 1903, when 260,900 tons of ore was mined, the power consumption of the Bunker Hill & Sullivan was 288,000 kw.-hr. per year; in 1915, when 455,000 tons was extracted, there was 10,979,000 kw.-hr. consumed. Substation capacity increased 15 times. In 1915 mine properties used 29,508,711 kw.-hr., for which was paid \$214,190. Milling requires the largest proportion of the load at each mine. The article mainly deals with the utilization of power at the Bunker Hill & Sullivan mine.

ELK CITY. In the Marshall Lake district the Fox mine is yielding \$1000 of gold daily. In three months the total was \$76,000.

KELLOGG. The Douglas zinc mine in the Pine Creek district, operated under lease by the Anaconda company of Butte, is shipping 30 tons of ore daily. A compressor is being installed. Nearly 50 men are employed. A royalty of \$3 per ton is paid the Douglas company by the Anaconda.

MISSOURI

JOPLIN. Owing to a slump in spelter the zinc-ore market declined \$10 per ton last week. A sudden severe cold spell reduced operations 75%. The output of the Missouri-Kansas-Oklahoma region was 6759 tons of blende, 439 tons of calamine, and 1174 tons of lead, valued at \$688,497. For five weeks the total is \$3,331,807.

NEVADA

A bill before the State Legislature provides for a State assayer and inspector at a salary of \$3000 per annum. He is to be appointed for four years, and can employ deputies at \$5 per day. The duties of the new position are to watch and check consignments of ores to smelters for shippers.

From March 1895 to the end of 1916 the Nevada State Mining Laboratory has made 57,357 determinations on 14,825 samples of rock submitted by 7654 individuals. For 10 years

PART OF NEVADA, SHOWING SITUATION OF MANHATTAN.

the institution was little used, but from 1901 it became of importance. During 1916, 1651 people sent in 3236 samples, necessitating 12,565 determinations. This is 50% above 1915, which was 25% greater than in 1914. The present daily rate is 7 samples. V. M. Henderson is doing most of the work at the laboratory.

GOODSPRINGS. The report of F. A. Hale, Jr., general manager of the Yellow Pine Mining Co., contains the following concerning 1916:

The Bybee mine produced 22,662 tons of ore at a cost of \$3.81 per ton. Of this, 2081 tons was shipped and 20,581 sent to the mill. Development, 3358 ft., cost \$9.31 per foot. The 300 sub-level opened high-grade ore. A winze below this passed through 50% zinc-lead ore. A cross-cut and raise on the 700-ft. level are to develop this orebody. The mill treated 20,581 tons of ore averaging 10.5% lead, 30.4% zinc, and 4.53 oz. silver per ton, at a cost of \$1.66 per ton. There was shipped 2294 tons of lead concentrate containing 54.2% lead, 13.2% zinc, and 20.2 oz. silver; 14,240 tons of zinc concentrate

assaying 4.48% lead, 32.22% zinc, and 2.27 oz. silver; and 3570 tons of zinc-slime with 6.25% lead, 33.5% zinc, and 3.6 oz. silver. The crude ore carried 6.25% lead, 37.6% zinc, and 3.42 oz. silver. Net receipts totaled \$986,315. Total costs were \$9.919 per ton, and profit \$34.537 per ton. Dividends amounted to \$800,000. The bank balance is \$58,124, and special reserve fund \$94,000. It is intended to produce on the same scale during 1917.

MANHATTAN. Placer deposits of this district are described by H. G. Ferguson in Bulletin 640-J of the U. S. Geological Survey. Gold ore was discovered at Manhattan early in 1905, since when over \$3,000,000 has been extracted, probably too low a total. Placer mining contributed \$1,000,000 to this amount. The gravel deposits are of three types, namely: the old gravels, still existing in small patches along the side of Manhattan gulch above the present stream-level; the deep gravels of the gulch; and the surface wash and shallow stream-gravels in the immediate vicinity of the lode outcrops. The placers are all worked by drift mining, as the overburden is too thick for dredging or hydraulicicking, even if there were sufficient water available. There is a constant flow (20,000 to 50,000 gal. daily) of water through the pay-gravels along the greater part of the deep channel. This water is used for washing the gravel in the sluice-boxes. Trimming is done mostly by barrows. The cost of mining at a well-equipped property is rather more than \$1 per cubic yard. Most of the work is being done by Serbian and Italian lessees. The dry-washing machines recover only 70% of the gold, the wet methods much more.

NEW MEXICO

The Oaks Company paid its third monthly dividend on February 1. An option has been taken on the Maud S. mine, which has produced \$500,000 in the past.

STEEPLEROCK. It is authoritatively stated that August Hecksher (of New Jersey Zinc Co.) and associates have purchased the controlling interest in the Carlisle Mining Company. The mine was originally owned by Marshall Field, L. Z. Leiter, and N. K. Fairbanks, of Chicago, and was a large gold producer during the early eighties, with a production record of over \$6,000,000. About 1887, the Carlisle was sold to a London exploration company, which operated it for several years. As depth was reached, the ores become a mixture of gold, silver, copper, lead, and zinc, impossible to treat profitably by any known method. The Carlisle was closed in 1890, and allowed to fill with water. The present owners have unwatered the mine and have discovered a large quantity of ore, all of which is now amenable to profitable treatment under improved metallurgical processes. A 125-ton mill is now being erected on the property, and is to be enlarged several times that capacity.

OREGON

KERBY. The black-sand plant of T. W. Gruetter makes it profitable for miners to save their concentrates and have them treated there for recovery of rusty gold and platinum. Some miners send their black sand without first panning or amalgamating, thus saving time for sluicing.

TEXAS

EL PASO. The suit tried in the 41st District Court by Judge Price before a jury on January 8 was brought by C. A. Bentley in the name of the San Roberto Mining Co. of Zacatecas, Mexico, against the American Metal Co. and Penoles Mining Co. for breach of contract. The American Metal Co., through a subsidiary company, Minerals y Metales, had made a contract for the purchase of 10,000 tons of zinc ore from the San Roberto properties on March 27, 1915. The metal company broke this contract, alleging many and diverse reasons for doing so. Mr. Bentley brought suit against the company for breach of contract, and asked for \$390,000 damages. The jury,

by a unanimous verdict, gave him approximately \$70,000 damages, a verdict rendered at El Paso on January 13. It is thought that this is only a beginning of a number of other suits. It is not known at this time whether or not the defendant companies will appeal.

UTAH

ALTA. The tunnel of the Alta T. & T. Co. is in 2400 ft., in favorable formation with a strong flow of water from the face.

AMERICAN FORK. Mine operators in the American Fork district are making plans for the establishment of the American Fork Bureau of Mines for the purpose of giving publicity to the legitimate opportunities of the mining industry in that district, and to disseminate accurate and official information regarding the objects and progress of development plans being carried out at the various properties. The Bureau will have offices in the Salt Lake Stock & Mining Exchange building.

PARK CITY. This growing district produced 6943 tons of ore and concentrate during January. The Silver King Coalition led with 2313 tons, followed by Judge Smelting with 1210 tons, Silver King Co. with 1035 tons, and Daly West with 864 tons.

TINTIC. This district produced 40,000 tons of ore and concentrate in January, worth \$1,000,000. The Chief Con. led with 7000 tons, followed by Dragon Con. 6600, Iron Blossom 5000, and Centennial Eureka 4500 tons.

CANADA

Dividends paid during January totaled \$1,255,580. Companies paid \$854,392 from Cobalt, \$306,000 from Porcupine, and \$65,188 from Kirkland Lake.

COBALT. The Beaver Consolidated has cut 6 to 8 in. of rich silver ore on the 1600-ft. level. This is at the lower contact. This is of great importance to the mine and the district. As the Temiskaming company is also exploring along the contact, these two mines are to be connected at 1600 feet.

MEXICO

Companies operating in Mexico are annoyed at the new labor law, and some contemplate closing mines. The A. S. & R. Co. intended resuming at No. 3 smelter at Monterrey toward the end of January, but on account of the new regulations has decided not to start. The Minas Viejas and Villadama calciner are working. The Paloma and Cabrillas Monterrey are shipping ore. The Providencia and Abarradon Mazapil districts shipped several thousand tons last month.

SONORA

Increased activity is reported from several districts in this State, in spite of interferences. The well-known El Tigre, Cananea Consolidated, and Moctezuma companies are working regularly.

The CANADIAN MINING INSTITUTE will hold its 19th annual meeting at Toronto on March 7, 8, and 9. A number of interesting papers are to be read.

The short course for prospectors, miners and millmen, offered each year by the UNIVERSITY OF IDAHO at Moscow, continues until March 8. The work offered includes studies in chemistry, mineralogy, petrology, geology, prospecting, mining, assaying, ore dressing, and milling. E. K. Soper and R. R. Goodrich are the professors in charge of the work.

The LAKE SUPERIOR MINING INSTITUTE will assemble at Chicago on March 10, afterward leaving for Birmingham, Alabama, where the 21st annual meeting is to be held on March 13, 14, and 15. The invitation was extended the Institute through Edwin Ball, general manager of the Tennessee Coal & Iron Co., and C. T. Fairbairn, manager of the Republic Iron & Steel Co. Knoxville, Tennessee, will also be visited. A. J. Yungbluth is secretary at Ishpeming, Michigan.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

HOWARD D. SMITH is at New York.

C. D. KAEDING is at Mason, Nevada.

CHARLES C. RUEGER, of Butte, is visiting at Berkeley.

STUART CROASDALE, of Denver, called during the week.

ERNEST R. WOAKES has left London to go to South America.

H. E. CRAWFORD was here from Los Angeles during the week.

B. BRITTON GOTTSBERGER has returned from New York to Miami.

D. W. BRUNTON sailed on the *Ecuador* for Shanghai on February 12.

HUGH ROSE has opened an office at 487 Mills building, San Francisco.

ALBERT L. WATERS has gone to Kelvin, Arizona, for about four weeks.

FRANK E. MARINER, president of the Pensacola Tar & Turpentine Co., was in San Francisco during the week.

JAMES F. HOWARTH, of Wallace, Idaho, is at the Palace hotel, San Francisco.

J. F. MITCHELL-ROBERTS has returned from Denver and Globe to San Francisco.

E. A. STROUT, formerly superintendent of the La Fe mine in Zacatecas, is now at Los Angeles.

H. T. LIANG, of the Wah Chang M. & S. Co., is returning from New York to Changsha, China.

E. C. MORSE is watching tests being made by the Chino Copper Co., at Hurley, New Mexico.

A. A. COLE has been nominated by acclamation for the presidency of the Canadian Mining Institute for 1917.

JULIUS STIEGLITZ, of the University of Chicago, has been elected president of the American Chemical Society for 1917.

J. P. BICKELL of Toronto has been chosen president of the McIntyre-Porcupine Mines Co., of Porcupine, Ontario.

FORBES RICKARD passed through San Francisco on his way to the Atolia mines, in San Bernardino county, California.

HORACE V. WINCHELL, accompanied by IRA B. JORALEMON, sailed by the *Protecelaus* from Seattle, for Siberia, on February 16.

JAMES W. HUTCHINSON and EUGENE G. SNEDAKER, of the Goldfield Consolidated Mines Co., were in San Francisco during the week.

CHARLES H. DOOLITTLE has resigned as general manager for the Utah Metal & Tunnel Co. to devote all his time to his American Fork interests in Utah.

W. R. INGALLS has been appointed chairman of the committee of consulting engineers on mining law revision by the Director of the U. S. Bureau of Mines.

FRANK A. VESTAL, who has been superintendent of the cyanide plant at the Empire mine for several years, is now with the Grass Valley Consolidated Gold Mines Co.

ERNST TWITCHELL, of Cincinnati, has received the Perkin medal for 1917, from the New York section of the Society of Chemical Industry, for his research in applied chemistry.

The U. S. Civil Service Commission announces an open competitive examination for designing-mechanical engineers to fill a vacancy under the Board of Engineers, U. S. Army, at New York, at \$2100 per year. The duties of this position are those of an expert designing mechanical engineer, familiar with structural steel and reinforced concrete, and will include the designing of mechanical equipment and material pertaining to permanent fortifications, heavy mobile armament, and armored railway trains. As insufficient eligibles were secured from the examination for this position of November 21, 1916, qualified persons are urged to apply. Applications must be filed by March 6.

THE METAL MARKET

METAL PRICES

San Francisco, February 13.

Antimony, cents per pound	24
Electrolytic copper, cents per pound.....	35
Pig lead, cents per pound.....	8.75—9.75
Platinum, soft and hard metal, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	\$140
Spelter, cents per pound	12
Tin, cents per pound	48
Zinc-dust, cents per pound	18

ORE PRICES

San Francisco, February 13.

Antimony, 50% metal, per unit.....	\$1.00
Chrome, 40% and over, f.o.b. cars California, per ton.....	18.00—20.00
Magnesite, crude, per ton.....	8.00—10.00
Manganese, 50% (under 35% metal not desired)....	16.00
Tungsten, 60% WO ₃ per unit.....	17.50—18.00

New York, February 7.

Tungsten: Quotations are firm at \$17 per unit. The market has been adversely affected by the uncertainty of international affairs, but yesterday (February 6) considerable business was done in immediate deliveries. Congested freight conditions cause spot sales to be favored, material which left the West in December not having yet arrived.

Molybdenite: The market is nominally \$1.80 per lb. for 90% concentrate. If prompt supplies were available a good business could be done as foreign buyers are inquiring.

Antimony: Business has been done at \$1.85 per unit.

EASTERN METAL MARKET

(By wire from New York.)

February 13.—Copper is strong and closely held. Lead is active, spot metal bringing premiums. Spelter is fairly active and firm.

COPPER

Prices of electrolytic in New York, in cents per pound.

January copper production of important mines, in pounds, was as follows: Braden, 4,798,000; Kennecott, 7,080,000; Shannon, 759,000; East Butte, 1,479,520; Greene-Cananea, 5,700,000; Old Dominion, 3,000,000; Shattuck, 1,415,303; Cerro de Pasco, 6,152,000; Miami, 5,020,370; Inspiration, 11,600,000.

The total production of Miami in 1916 was 53,518,331 lb. of copper at a profit of \$8,200,000.

The Champion company has declared a dividend of \$6.40 per share, and the United Verde \$1.50 per share.

Nine copper mining companies in January paid dividends aggregating \$6,961,834.

The "Times of India" says: "The absorption of nearly 400,000,-

000 rupees in twelve months (of which about 100,000,000 are estimated to have gone to Mesopotamia and East Africa) is without precedent in the financial history of India and is due to trade conditions since the middle of 1915. The people of India have been paid in crores for which produce has been going up in value and they retain these crores because they have not been able to buy freely imported articles like piece goods, iron and copper goods, bar silver and gold." (1 rupee = 30 cents.)

LEAD

Lead is quoted in cents per pound, New York delivery.

ANTIMONY

Spot antimony is difficult to obtain, even at 25c., duty paid, the reason being the uncertainty of shipments from the West. In futures there is no business, the nominal quotations being 13 to 14c. in bond.

ALUMINUM

No. 1 virgin aluminum, 98 to 99% pure is strong at 57 to 59c. per pound.

PLATINUM

Price of platinum, New York is \$105 per ounce for soft metal and \$110 for hard.

Eastern Metal Market

New York, February 7.

International events have inspired a feeling that great caution is necessary on the part of all engaged in the metal trade. Everyone is waiting developments.

There is no copper market. The producers reiterate that they have no metal to sell for delivery before June and July, while second-hands are afraid to let go of their holdings. Quotations are therefore entirely nominal. Exports are almost at a standstill; meanwhile millions of pounds are accumulating at this port, the ultimate disposal of which can only be conjectured. If fed to the market lower prices undoubtedly will ensue.

Zinc is showing greater strength, but not much is doing, the producers being unwilling to sell except to satisfy the needs of actual consumers.

More than any other metal, lead is suffering from the congestion of railroad freight. For prompt metal, over 9c. has been paid. Great Britain has imposed on lead restrictions similar to those which cover copper.

Tin has again reached 55c., partly because consumers are building up reserves, and because of fear that shipments from the Far East may be interrupted. The possibility of shipping by way of the Pacific appears to be more or less overlooked.

Antimony is scarce and higher.

As was expected, because of the difficulty in securing deliveries of coke, the January production of pig-iron fell off, the production being 3,150,938 tons, against 3,178,647 tons in December. The daily rate was 101,643 tons, or about 900 tons less than in December. The total number of furnaces in blast on February 1, was 312, one more than on January 1.

Uncertainty over future shipments of ferro-manganese by England is a disturbing feature to the steel trade. Domestic makers have advanced prices to \$250 per ton, a rise of \$50.

COPPER

In keeping with the times, the situation in the copper market is unprecedented. Uncertainty fills the air and is responsible for a deadlock. Except for the occasional sale of a small lot, under circumstances which do not make the market, there is no activity, and prices are absolutely nominal. If a quotation for prompt delivery must be had, the best that can be done is to take the last quotation at which business was done—somewhere around 33c.—and call it the price. As a matter of fact, a leading metal journal which gives daily prices, temporarily dropped its table of quotations. Producers constantly reiterate that they have no metal to sell this side of June and July, and that for these months their price is 30 to 31c. It is unquestioned that second hands hold large quantities of copper, but they are afraid to let it go. A few exceptions come to light, of course, as in the case of a consumer who offered a small quantity, February 5, at 34.50c., cash. The export trade is practically at a standstill because no boats are sailing. Ships that might take the metal are behind their schedule in getting here. Of course, the Entente Allies will continue to get our copper, perhaps to a greater extent than heretofore, but temporarily there is a halt and in consequence copper is accumulating at the port of New York and elsewhere. The ultimate disposition of this metal is a natural subject of speculation. Millions of pounds are in New York awaiting export shipment, and while the movement to tide-water has lately been restricted by the railroads, more or less continues to come. Among the questions which the trade is vainly asking itself are these: Will the excess stocks awaiting export be thrown on the market? If war with Germany is declared will the metal be commandeered by the Government? Will the Government pay what the European nations have paid? If the Government does commandeer these accumu-

lated stocks, will there be one price for the United States government and another for the private consumer? The only answer is that the people are in a fair way to learn what a full-fledged embargo means. Lake copper, though accounted by some a shade easier than electrolytic, cannot be had for prompt delivery. The exports, February 1 to 7, total only 4148 tons. Electrolytic at London is higher at £145. A week ago it was £143.

ZINC

The spelter situation also is dominated by fear of the war cloud. The producers are not anxious to sell, except to supply specific needs. They are particularly not desirous of stocking up jobbers or other second hands at present prices. On February 5, February delivery was easily obtainable at the equivalent of 9.50c., St. Louis (9.75c., New York), but early the following day, the market firmed up to 10 to 10.25c., St. Louis—10c. St. Louis, being paid for 200 tons of March delivery. With ore quoted, February 5, at \$80 it is not surprising that the producers were not anxious to sell, for it meant that it cost about 9.50c. to produce the metal. On the afternoon of February 6 inquiry for several hundred tons of February to second quarter developed. At that time, brass-mill grades were quoted around 11c., delivered. In the past few weeks the extreme cold which has prevailed in the middle West has cut down production to a great extent through its curtailment of the natural-gas supply. There has been insufficient pressure to force the gas through the mains, and in some cases the available supply was conserved for other purposes. The exports, February 1 to 7, totaled 1110 tons. The London quotation for spot was unchanged yesterday (February 6) at £47. Sheet zinc is unchanged at 21c., carload lots, f.o.b. mill, 8% off for cash.

LEAD

The congestion of freight on the railroads dominates the position of lead. The situation will be understood from the fact that lead that has been en route from the West for three months has yet to arrive in New York. Spot lead has been sold at prices ranging from 9 to 9.25c., New York. Prompt shipment and the usual 30-day delivery, are regarded as specialties. March delivery can be had at 8.50c., New York, and 8.30c., St. Louis. While it is true that an occasional carload gets through, it is not enough to relieve the situation. It is through increased arrivals, irregular as they may be, that the situation will be finally straightened out. In the West there is plenty of metal; the entire problem is in getting it East. For one recent arrival 9.50c. was quoted, a figure which proved unattractive to buyers. The exports February 1 to 7 were only two (2) tons.

TIN

The January statistics, showing that 7177 tons of tin was delivered into American consumption that month, was a bull influence on the market, and between January 31 and February 2, between 400 and 500 tons changed hands. It is believed that a large part of the deliveries mentioned were taken by consumers as a reserve in case Germany's submarine activity should seriously interfere with imports. Under the stimulus of the large buying, and the uncertainty of the future, quotations have advanced radically, the quotation yesterday for spot Straits being 55c. and for spot Banca, 52c. Fears as to future deliveries are held by many to be unfounded, as shipments can be made by way of Pacific ports without much likelihood of interference by submarines. But the tin market is always ultra-sensitive. The monthly statistics also show that the total world supply at the close of January was 18,169 tons, or 2568 tons less than at the close of December. There is afloat 4248 tons.

Mining Decisions

COAL LEASE NOT TAXABLE

A leasehold interest with the privilege of mining coal for a period of 19 years does not convey any title to the coal in place, and is not a taxable interest in real estate under the laws of Alabama.

State v. Roden Coal Co. (Ala.), 73 Southern, 5. Nov. 16.

AUTHORITY OF MINING CORPORATION PRESIDENT

Authority to the president of a mining company to sell its mine for a certain price is not authority to employ another person to make the sale, in the absence of a showing that he was held out by the company as having general authority to make such employment.

Huey v. West Ossipee Mine Co. (New Hampshire) 99 Atlantic, 93. October 3, 1916.

GAS LEASES FORFEITURE WAIVED

An oil and gas lease not containing any provision that time was of the essence of the contract required the lessee to drill a well within 90 days. Six months elapsed of the one-year term of the lease, and then without notice to the lessee or claim of forfeiture the lessor executed a second lease. Thereupon the first lessee went into possession and put down a producing gas well. Held, on suit of the second lessee to oust the first one, that the failure of the lessor to insist promptly upon a forfeiture for failure to drill within the agreed time amounted to a waiver and the subsequent entry of the first lessee within the period fixed by his lease, and bona fide drilling operations established his right to continue for the term.

Bloom v. Rugh (Kansas), 160 Pacific, 1135. October, 13.

MINERAL OPTION: DEVELOPMENT WORK UNNECESSARY

An agreement called for a deed to an undivided interest in certain mineral and timber land and a 50-year option for the purchase of the remaining interest with the right, but not the express obligation of entering upon and exploring the property for mineral and timber. A cash consideration of \$17,000 passed. Owing to the lack of transportation facilities for ore shipments the optionees made no attempt for 15 years to enter upon or mine the property. Held, on suit by successors in title of the optionors to have the option declared forfeit, that there was no obligation upon the optionees to enter and explore for mineral; that the consideration of \$17,000 supported not only the land purchase but also the grant of the option on the remainder.

Mineral Land Investment Co. v. Bishop Iron Co., 159 Northwestern, 966. November 17, 1916.

REGISTEE'S CERTIFICATE OF ENTRY: EFFECT OF

The mere acceptance by the Register and Receiver of a local Land Office of the purchase price of a placer entry and the issuance of a Register's certificate, does not bar the United States during pendency of the matter in the General Land Office of the right to sue for cancellation and annulment of the interest of the applicant on the ground of fraudulent entry made in contravention of the oil-land withdrawal order of 1909. While the expiration of the period within which adverse claims might be filed would bar private applicants from contesting the entry, the Government itself is not thereby barred, nor is it necessary that contest by the Government be initiated in the Land Department where suitable grounds for intervention by a court of equity are set up in the complaint, such as fraud, necessity for receiver's appointment or other matters not within the Land Department's jurisdiction.

United States v. Devil's Den Consolidated Oil Co. (California), 236 Federal, 973. October 4, 1916.

Book Review

ELEMENTARY CAMS. By Franklin DeRonde Furman. P. 90. Ill., index. John Wiley & Sons, New York, 1916. For sale by the MINING and SCIENTIFIC PRESS. Price, \$1.25.

In the preface the author says, "This book has been prepared with a view to gathering the various types of cams that are in common use . . ." Naturally we looked for something on stamp-mill cams, of which there must be at least 30,000 in daily operation in the many mining centres of the world—including 6000 in the United States—but we found no mention of this important cam, upon which so much study in design and metal has been given. From this point of view we are disappointed with the work, and it is difficult to see how the author overlooked stamp-mill cams. A cam is a peculiar piece of mechanism. Its shape may be described as the involute of a circle, slightly modified at the end so as to retard gradually any desired motion. The design of cams involves many problems, and in this book they will be found discussed. Cams are used in most machinery, ranging from those operating valves in automobiles, the intricate gear in a linotype, valves on a steam-engine, gear on machine-tools, and the heavy double-arm cam lifting gravity stamps for crushing gold and silver ores. Mechanics will find this book of value.

EDITORIAL

T. A. RICKARD, Editor

THAT oil may be discarded eventually in flotation work is suggested by the success of the Freeman process at Broken Hill.

RHODESIA'S output of gold last year was worth £3,895,311 or \$18,892,258, this being £72,145 or \$349,903 more than in 1915. The largest producer is the Shamva, which contributed £36,054 from 51,360 tons in December.

CANADIAN consumption of cyanide is estimated at 1500 tons per annum, or slightly less than the quantity used for fumigation in the orange-groves of California. Ontario consumes 120 tons per month and British Columbia 8 tons per month.

THE nineteenth annual meeting of the Canadian Mining Institute is to be held at Montreal during the three days beginning on March 7. Mr. Arthur A. Cole has been re-nominated for the presidency by acclamation. A promising list of papers is announced.

COTTRELL patents for Japan have been acquired recently by a syndicate composed of the Ashio Copper, Furukawa, Sumitomo, and Kuhara companies. We are informed that \$150,000 in cash was paid to the Western Precipitation Company for the use of these patents both in metallurgical and industrial plants.

SOME thoroughly bad work is being done in flotation in mills that we do not care to mention. This failure is due largely to lack of experience and the inability to ascertain the modification most suitable to a particular ore. In many cases the flotation practice is compelled to adapt itself to a pre-existing flow-sheet, which may be defective, particularly in the grinding department.

BRITISH efforts to obtain sufficient tungsten and to control a sure supply for the future have led to the formation of an organization called High Speed Steel Alloys, Ltd. This is composed of 31 of the biggest manufacturers of steel in Great Britain. The company has taken steps to secure the Burmese and Malayan output of tungsten. An office has been established at Tavoy, in Burma, where a large laboratory is now serving to investigate the supply of wolfram and other tungstates obtainable in the Malayan peninsula and its hinterland. Meanwhile our domestic price of tungsten remains fairly strong and steady, the production having become less feverish. Some sort of regulation of the tungsten output from California, Nevada, Arizona, and Colorado is

likely to be effected, so that the mines will not be wholly at the mercy of the steel-manufacturers.

NOTICE is reported to have been given by the Mexican government that mining properties not operated for two months, and controlled by owners that have not made application for an extension of the time-limit within which the properties had to be started to work, will be seized by the Government. It is also rumored that Villa has gone to Japan. These items of news, like others from the southern side of the Rio Grande, are 'important if true.' Meanwhile the United States is again represented diplomatically at Mexico City, Mr. Henry P. Fletcher having reached his new post.

A FRENCH-CANADIAN prospector writes to a friend of ours concerning a new theory of ore deposition, whereby "iron was made by the sedition of water." He quotes several "authorities way up in the profession," more particularly a certain T. A. Rickard, who is described as State Geologist of Colorado, and is said to have delivered an address before a meeting of geologists at Buffalo, in October 1898, in which he said: "Mineral has come to surface by volcanic eruption, erosion, and overflow of the lava." To which our prospector adds: "The school of France says it short '*la fusion*'." So is a man's reputation stolen from him. 'Tis a sad world.

DESPATCHES from Belgium, and a telegram from Mr. Hoover himself to the San Francisco representatives of the Belgium Relief Commission, indicate that the good work is still proceeding and that it will proceed. The orders given by the German officials compelling the American Relief workers to get out of Belgium have been rescinded, so that they can remain at their posts under the conditions existing before the break in diplomatic relations between Washington and Berlin. Sufficient reserves of food are stored in Belgium to allay any fear of immediate famine pending the arrival of further shipments, which are now again on the move. Mr. Hoover desires all sympathizers with the good work to know that further financial support may be sent without the fear that it will prove ineffective. Send your subscription for the children to Belgian Kiddies, Ltd., 120 Broadway, New York.

OPTIMISM is a good quality in mining; without it the industry would soon become senile; but too much of it is intoxicating. In an Idaho paper we read about the 'New Demming Gold Fields' and this is how the

article starts: "The rain had fallen throughout the first day of my examination. Just at sunset the clouds broke and my friend said, 'Look at the wonderful rainbow.' I said, 'Yes, and this is the end of it.' 'Do you think so?' he asked. 'Yes,' I replied, the 'dream of the mining geologist is fulfilled.'" This rhapsodical fragment is worthy of a better cause. The dream includes "ores that harken back to the Archean" and invade Tertiary rocks. Gravel covers the ridges. "The eschar of these gravels prove to a strong extent the product of a thermal (aqueous) crater area and have no significance with the later impounded fresh waters." Thus the dream passes into a nightmare of pseudo-scientific jargon and the rainbow hues of the poet fade into the murk of turgid writing.

MINING on the Indian reservations is the subject of a bill now before Congress. It has been passed in the House and has been reported favorably by the Committee on Indian Affairs. Over 30,000,000 acres of land remains unallotted on the Indian reservations and large tracts within this acreage are known to be mineral-bearing. The American aborigines do not engage in mining, having neither the skill nor the capital required. These lands, however, are the tribal property of the Indians and for that reason it has not been the policy of the Government to permit mining on the reservations. They have been set aside for the exclusive use and benefit of the Indians, who are entitled to receive an income from such property, if leased. It is proposed to exploit the mineral land under a leasing system. In Arizona alone 19,551,045 acres is unallotted, not including the new Papago reservation, on which the mineral land has not been withdrawn from entry. Mr. Will L. Clark, of Jerome, has taken the matter in hand and is co-operating with Arizona's representatives in Congress.

DISCUSSION this week starts with the remarkable letter from Mr. Hedley D. Crowder, proving the part played by his father in the origination of the Elmore bulk-oil flotation process. We discuss the matter on another page. Next comes a letter from an old friend in Australia, a mine manager that chooses to hide his identity under a literary pseudonym. He makes a plea in behalf of Charles V. Potter. We second his plea, for the record shows that the first mill unquestionably successful with the flotation process was the one that used Potter's method on the Block 14 mine at Broken Hill in 1903. The Potter-Delprat process scored the first commercial success, for the Elmore bulk-oil method won no permanent foot-hold in metallurgy, while the Broken Hill Proprietary mine is still using the Potter process on a large scale, as modified by Mr. Delprat, the manager of that mine. Mr. Loring Hanson, who is engaged in mining at Adelaide, in Humboldt county, Nevada, records sundry observations on seismic unrest. We do not wonder that he and his friends feel uncomfortable, but, as far as the evidence goes, they need not fear to go underground. That is safer—during an earthquake—than the surface. Mr. Edwin Higgins, recently with the U. S.

Bureau of Mines as an Inspector, gives his testimony concerning the best way of preventing misfires, replying to Mr. Brooks. Mr. Fred. G. Tyrrel throws some light on the difficulties inherent in the sampling of small lots of ore, controverting sundry statements made by the contributor that signed himself 'Lovejoys.' The subject is one to interest many of our readers and we look for further contributions to this discussion.

AUSTRALIAN mining affairs are interesting to such of our readers as have a wide mental horizon. For that reason we draw their attention to the long letter appearing last week from our Melbourne correspondent. He deals with the metal trade and the upset that followed the incidence of war. The adviser that the Australian premier, Mr. W. M. Hughes, had at his elbow is said to have been Mr. A. H. Higgins, of Chillagoe fame, but we have reason to believe that Mr. W. S. Robinson was consulted frequently by the Premier. In their effort to break an international or non-national cartel of metal merchants the Australians have swung to the other extreme of commercial parochialism. It is too violent and narrow-minded to last. Business finds the cheapest market as surely as water flows downhill. Our correspondent gives a number of interesting details concerning the zinc industry of Broken Hill. The outlook for mining—especially mining for gold—in Australia is not good. Several famous mining districts are approaching exhaustion and the domination of the Labor party appears to have unduly harrassed the operators of mines.

The Presidency of the Institute

We learn by telegraph that Mr. Philip Moore has been elected president of the Institute after a close contest. Over 2000 votes were cast. This number, out of a membership of 5000, indicates that great interest was taken in the election—which is a good sign, for interest is closely akin to loyalty. Mr. Moore will make an excellent president, and so will his competitor, Mr. Sidney Jennings. We suggest that Mr. Jennings be placed in nomination forthwith and elected unanimously next year. Thus we can gain the benefit of the interest aroused without any of the permanent harm. If this is not done, we shall see a campaign even more unpleasant in some respects than the one just ended, perpetuating the cleavage between the 'stand-patters' and the reformers. That will do no good and it may contain the possibilities of much harm. The idea that a coterie in New York selects the president irritates many Western members, even if the idea lack sound foundation; so also the suggestion that the big mining corporations exert a preponderating influence on the directorate. Such notions can be cured by changing the methods of selection. Why not have a Nominations Committee composed of all the chairmen of the local sections together with the President and the two Vice-Presidents of the Institute *ex officio*? Then invite nominations for the presidency and vice-presidencies, and

ask members to submit their views frankly to the committee, which would thus be well fortified to act, avoiding the unpleasant kind of campaign to which we have been treated recently, and yet ascertaining the desires of the general membership. Men of the highest type will not be willing—they will refuse—to enter a personal contest for such an honor as the presidency. If we are to have these unseemly competitions we must make up our minds to forego the presidential service of some of the best men in the profession. The old way of running the Institute like a close corporation was objectionable, as we know now, but the new scheme of a campaign of vote-solicitation is equally objectionable. If we must have campaigns to awaken the Institute periodically let it be through the election of directors. By all means let the Nominations Committee give us a choice of directors, by nominating at least twice the number required. That will afford occasion for ventilating our opinions on matters of policy and organization, and for selecting those whom we wish to act as trustees for us. We shall be glad to publish expressions of opinion on this subject.

Crowder-Elmore—Flotation

In our issue of September 23 we published an appeal made to the profession by Mr. A. Stanley Elmore, in behalf of himself and his brother Mr. Francis E. Elmore, setting forth their claims to the original discovery of the flotation process, and reciting the shabby treatment to which they were subjected by the Minerals Separation people, notably Messrs. Ballot, Sulman, and Picard. We commented in friendly fashion on this *argumentum ad hominem* and expressed our belief that the service done by the Elmore brothers to the development of flotation, by their mechanical ingenuity and by their persistent publicity of the process, had not been adequately recognized. We hold to that belief still. In the course of his recital Mr. Stanley Elmore claimed that his brother Frank had been led to his invention of the flotation process by observing the accidental concentration of chalcopyrite in the oil that had dripped upon a launder from a shaft-bearing, and also by remarking the fine particles of mineral collected at a spot where a greasy hand had been laid upon an iron pipe. In commenting on this Newton-like story, we stated that we had always been under the impression that the Elmores obtained the idea of oil-concentration through the fact that experiments in the use of oil for concentrating ore had been made previously at the Glasdir, the Welsh mine where George Robson and Samuel Crowder had preceded the Elmores in an effort to treat a low-grade copper-bearing gold ore. We supposed that Mr. Frank Elmore must have been aware of the previous work done on the same spot and must have seen some of the discarded apparatus left by his engineering predecessors. To this Mr. Stanley Elmore replied in our issue of November 18, 1916, stating that there was "not a word of truth" in our supposition. "not a shadow of justification for any one of the sug-

gestions or innuendoes or whatever they may be." He followed this by a particular denial of the use of Robson's machine, and an explanation that all of the Robson & Crowder plant had been removed before he and his brother arrived at the Glasdir mine. He underlined the assertion that "Frank Elmore has not at any time even seen a Robson & Crowder machine" and mentioned a letter from Crowder in which the Elmores were congratulated upon their success "made where he and Robson had only encountered failure; and in which he compliments us [the Elmores] on having discovered the one thing essential to success which had always eluded them [Robson and Crowder]." In commenting on this editorially in the same issue we said that Mr. Stanley Elmore placed too much emphasis on the Robson & Crowder "machine." We had not used the word 'machine,' but had written concerning "remains of Robson's experimentation, in the form of oil, pulp, and apparatus." We suggested then that "it would be worth while for Mr. Frank Elmore himself to publish an explicit denial and so kill the story conclusively." In saying so, we had nothing up our sleeve, but we did consider it remarkable that the two Elmores could go to the Glasdir mine without hearing about the experiments made on the same spot by Robson and Crowder or without seeing some remnants of such work, either in the form of apparatus or of oily discard. In due course we received a polite response from Mr. Elmore stating that he had no more to say. Between the date of our suggestion and his reply we received a letter from El Oro, Mexico, stating that the writer of it was the son of Mr. Samuel Crowder, who was still alive, but very old and feeble, yet in full possession of his mind and also in possession of a diary recording the events under discussion. The son, Mr. Hedley D. Crowder, asked to be allowed to defend his father's claims to credit in the invention of the flotation process, and we replied, of course, that he would be given an opportunity to state his case. That is how we come to publish the clear statement appearing on another page. We publish it with no sort of satisfaction, but with deep regret and as a plain matter of justice to all concerned. Mr. Hedley Crowder proves that the statements made by the Elmore brothers are highly disingenuous. The letter of Mr. Samuel Crowder of December 10, 1897, is convincing, unless Mr. Elmore can produce fresh evidence in rebuttal. The first Elmore patent for the bulk-oil process was taken out on October 18, 1898. Mr. Crowder asserts that the Robson plant was on the property when it was taken over by the late William Elmore, the father of the two patentees, in 1896. Mr. Crowder's notes, of 1897, show much practical sense. It is a curious fact that mill-men knew long ago that grease or oil aided the escape of gold from the stamp-battery and that the use of too much cyanide, for brightening the amalgamating plates, was attended with loss, but in neither case did they investigate closely; if they had, they might have lit on the principles underlying flotation on the one hand and of cyanidation on the other. Even the 'flouring' of quicksilver and the 'sickening' due to oil did not explain

the deleterious effect of grease. We know now that the greasing of a globule of mercury will cause bubbles of air to attach themselves in such a way as to buoy the heavy metal to the surface of the water. Mr. Crowder's suggestion of one pound of oil per hundredweight of ore comes very near to the famous "less than 1%," for the British 'hundredweight' contains 112 pounds. In his later letter, of 1899, he claims that the Robson process recovered 98 to 99% of the "metal," meaning gold, silver, and copper, but the experiments did not determine "the cost of manipulation." Of course, Mr. Francis Elmore's main contribution to the art was the mechanical ingenuity by aid of which he devised several effective machines both in the bulk-oil and in the later vacuum-oil method—the belated recognition of air itself as a prime factor in the process of levitation. Mr. Crowder's letter of 1901, quoted by his son in full, affords a pathetic commentary on Mr. Stanley Elmore's insistent claim for originality in the use of oil for concentration by his brother and himself. No wonder Mr. C. M. Rolker in 1900 called the process a "somewhat dirty and nasty" one. The whole history of it is full of unpleasantness. Our own belief is that inventiveness has played a minor part throughout and that the advancement of this metallurgic art has been due largely to manipulation, which is not patentable and has improved gradually, almost unconsciously. Given the idea of the flotative effect of oil, whether first suggested by Herodotus or Everson, or Jonah, it is possible by means of skillful manipulation to produce most of the results achieved today.

Water in the Desert

The necessity for placing more sign-boards and otherwise indicating the watering-places in the desert is receiving the renewed attention of many that are interested in the development of the resources of the Great Basin and of the dry tracts of southern California. The dangers of travel in arid regions are now well understood by those long accustomed to them, but in earlier years the lives of many travelers were lost through ignorance. All of the unfortunates were by no means inexperienced in the rough life of the West, or even of the desert, for among them were some that had spent years in the mining districts of the Mojave and the Colorado deserts, but apparently they had found themselves unexpectedly without water, and being unable to reach a place where it could be obtained, they perished. As the desert region became better known, it was learned that springs were far more numerous than had been supposed. Frequently the direction of these springs or water-holes from the main routes of travel was indicated by stones placed at the side of the road. Such signs usually were made of two rocks, one of which was set upright, and the other placed on top of it, with its longer axis pointing toward the spring. Many of these stone water-guides had been placed by Indians, and were observed and appreciated by most of the earlier travelers. Others, not familiar with Indian signs, and not realizing

their significance, kicked them over carelessly, and thus did a stupid disservice to later comers.

Several years ago an active and successful campaign was started in California to secure State aid in placing iron guide-posts along the desert roads. The Legislature made an appropriation for this purpose, and a number of public-spirited men gave valuable personal aid in the way of information, and also in setting up these guide-posts where they would be of greatest help. Generally they were placed at the forks of roads, or, in the case of water-signs, at the side of the road nearest a spring or water-hole that might be some distance from the road. On these guides were the names of towns and their distance, or they pointed to the nearest place that water could be obtained. Without doubt, they have contributed much to the convenience as well as to the safety of travelers through the desert regions. The United States Geological Survey aided the cause by the publication, in 1909, of Water Supply Paper No. 224, by W. C. Mendenhall, entitled, 'Some Desert Watering-Places in South-Eastern California and South-Western Nevada.' It contained a description of the position and character of a large number of springs on the desert. Unfortunately this book is no longer obtainable, the edition long since having been exhausted. Subsequently the Survey extended its work over the arid region of the South-West, and covered a good part of Arizona, New Mexico, and Utah, as well as Nevada and southern California, but much still remains to be done in the way of indicating the places where water may be obtained. Not only are maps needed but sign-posts, to be placed along the main roads and trails.

While it is true that springs and water-holes are much more numerous on the desert than is generally supposed, many of them are obscure and it is easy for a traveler to pass within a few yards of a spring and fail to be aware of it. Old Woman's spring, 45 miles east of Victorville, on the Mojave desert, flows several inches of water, yet a person might easily pass on the west close to it and never suspect that water was near. The spring issues from beneath a cliff of basalt that extends for a mile or more. In the Colorado desert there is a little water-hole about 11 miles north-east of Mecca. This spring is in the bottom of a gulch among rugged, but not high, hills of sandstone and shale. It is about 3500 ft. from the road, running through Box canyon from the railroad to Cottonwood spring. One of the Indian stone guide-posts marked it for the traveler years ago, but even when one knew of the existence of this water-hole it required care to find it, and the searcher came within 15 feet of the water before it could be seen. It was only a small spring with little or no water flowing, still it was sufficient to save human life, or even to succor a team of horses in an emergency. These two instances are examples of many such watering-places the whereabouts of which are not generally known. An effort is being made to secure an appropriation from Congress to develop and protect these watering-places of the desert, and to make their position known by means of metal guide-posts. We hope the effort will be successful.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Crowder-Elmore—Flotation

The Editor:

Sir—I am making what is undoubtedly a belated entrance into the discussion that has now been in progress for some months, as to who did, or did not, discover the oil process of concentration, now known as the 'flotation' process.

I have always considered my father, Samuel Crowder, and George Robson as the originators of the method of separating sulphides from crushed ores by the use of oil. Imagine therefore my surprise at reading A. S. Elmore's article entitled 'Notes on the Invention, Development and Introduction of the Flotation Process,' and the various articles based on it that have appeared in the technical press—their general tenor being to the effect that the Crowder-Robson patents and machine were never seen by the Elmore and that the work of the former was unknown to them.

Robson has been dead for many years, but Samuel Crowder, now well over eighty years of age, is still living, though in too delicate a state of health to allow of his entering the arena in his own defence. It so happens that, being a man of methodical habits, he has kept a diary during the greater part of his life. This diary is particularly complete covering the period in which he was working out the oil process.

As my father is resident in England it has taken me considerable time to receive from him the necessary data to present the Crowder-Robson case, more especially owing to the present disorganized state of the postal system.

Their case is best given in my father's own words:

"In the interest of historical truth, and the protection of Robson's reputation, I am sending you these particulars. At the start, however, please clearly understand that I do not wish to detract from Mr. Elmore's valuable developments of the invention.

"The fact is that for many years now, I have given up all interest in the process, and it was not until I saw the article from the MINING AND SCIENTIFIC PRESS of September 23, 1916, that it occurred to me that I ought to put a few facts on record as to the origin of the process.

"On the 18th of May 1892 I bought the Glasdir mine in Wales and in the same year I engaged George Robson as the manager. I may say in passing that the ore in the mine is of a very interesting and very deceptive character. After working for several years I found that the

gold was in the condition of 'float' and that it could not be caught by water. Finding that it was quite impossible to concentrate the ore, as I was trying to do, by water, I gave up working it, keeping Mr. Robson in my employ, and leaving him to fessick about and see if he could make any improvement in the method of concentration.

"For this purpose he tried paraffine, turpentine, and other things, and finally oil. He wrote to me that he believed he had found a method of concentration, and I at once fitted up a laboratory in the City and carried out exhaustive experiments, obtaining an extraction of 90% in some cases. We carried on experiments at the mine and erected an experimental plant.

"On April 15, 1896, I sold the mine to William Elmore, Sr., father of Frank Elmore, for the sum of £15,000, and when leaving his office I asked him how he intended to concentrate the ore. He said he had a plan, to which I replied: 'You will never concentrate that ore with water; *you can do it with oil* as our experiments have shown.' He treated the matter lightly and said that he was quite prepared for the difficulties.

"So the matter went on and he took possession of the mine. He very soon discovered that he could not concentrate the mineral with water. *My oil plant being still erected on the property*, I advised him not to pull it down at first, but to try and see whether it could be made effective.

"Later it came to my knowledge that Frank Elmore had claimed a patent for the use of oil in the concentration of mineral, on which I wrote the letter of March 18, 1901.

"Finding that Mr. Elmore could not carry on and had fallen on evil days, I wrote to him, and as an expression of sympathy returned him bills which were coming due, amounting to £2000.

"From the above it will be seen that Mr. Robson was the real discoverer, but that I took the matter over and paid all the costs and charges of working the mine and of Robson's experiments and patents.

"The discovery was made, as so many are, by accident. As already said, Mr. Robson was left in charge of the mine with instructions to see if he could improve upon the process we had been using. By accident he picked up a can of oil, and as he said, almost absentmindedly tried to concentrate some of the ore.

"The result was extraordinary and I spent a lot of money trying to develop the idea.

"This is the true genesis of the oil process.

"The original letters and papers are all in my possession."

I will now give some extracts from original correspondence proving that for some time after the Robson patent had been taken out, in 1894, my father continued to think over the oil process, and evolved ideas that must have been at least suggestive to anyone engaged in experimental work on the same process.

Under date of December 10, 1897, he sent a communication to A. S. Elmore in the form of notes, partly covering his ideas of the mode of occurrence of the gold and silver in the ore, and partly dealing with his ideas of how these values could be recovered from the ore by the use of oil.

The following are his notes dealing with the use of oil:

"10. Now respecting the use of oil for concentration. Of course, to anyone who has not seen the effect, it appears an absurdity and against natural law; be it so; the fact remains that the ore can be concentrated and all the metal saved by the use of oil.

"11. The action of oil with gold and sulphuret ores finely ground is so extraordinary that it must be seen to be appreciated—Query—we know that a very small quantity of oil in a battery-box will cause the loss of all the gold running over plates. The received theory is that it 'sickens' the mercury and prevents amalgamation—probably it does—but from what I have seen, I believe it picks out the gold and carries it away.

"12. Now, the experiment I want to see tried is this: Mix common petroleum with about 5% of any coarse oil and use a jet on the vanner, or rather the oil should be mixed with the wet slimes settled in the pits before it goes on the vanner. I cannot tell what quantity of oil would be required per cwt. of ore, but whatever it was, it could be saved by running it into a tank.

"Try it, and I think you will save your metal from the slimes. Try an exhaustive and fair experiment of one pound of oil mixed with 1 cwt. of slimes and gradually increase if required.

"13. Hurst's Company no doubt made a mistake when they refused to make a trial of the oil process at the time when the machinery was all fixed up in working order upon the mine and the trial could have been made without cost. I hesitate to suggest that the plant should be again erected, but it is the only process I have found to recover all the mineral contents.

"14. I feel sure that all the mineral can be recovered from the slimes by the plan suggested in No. 12, or some modification of it."

A year and a half later—to be exact, on July 28, 1899—my father, hearing from A. S. Elmore that they were not making a success of water concentration at Glasdir, sent him some further notes, substantially similar to those already referred to. I regret that considerations of space prevent my giving them *in toto*.

"As you [A. S. Elmore] are aware, the problem of working the Mawddach ore at a profit has been to me a

most interesting study, and one that has a kind of fascination for me, as I feel and have always felt that there must be some method by which all, or practically all, the metals should be saved.

"From what you told me, I understand you are not saving as large a percentage as you could wish.

"During the years the place belonged to me, the subject was, of course, an ever-present one to my mind, and many schemes and methods were considered and abandoned, *until we hit upon the oil process, which was in course of trial when you bought the mine*; undoubtedly that was a success so far as saving the metal was concerned, as 98% to 99% was recovered, the only question being the cost of manipulation. I am of opinion that this could have been reduced to a small amount, but the experiments were not carried far enough.

"The following notes are from my journal while working and the results of cogitation since, whether they are of any value I leave you to judge, probably you know more about the matter than I do, and have better plans for working than I could suggest, *but I think the idea of using oil, as proposed, is new*, whether it is practicable is quite another matter.

"The question is, would the introduction of oil into the launder feeding the vanner 'wet' the 'float' and carry it to a definite division? The question can only be determined by experiment; *the assumption is that a very small quantity of oil would be sufficient*, and that it would be afterwards nearly all recovered.

"In my humble opinion here are three most striking suggestions.

"1. The use of a mixture of a heavy and of a light oil.

"2. Selective action in the presence of a large quantity of water.

"3. The use of small quantities of oil, namely 1% of the weight of the dry ore."

A year and a half later, early in 1901, the Ore Concentrating Syndicate issued a pamphlet on 'Elmore's Process.'

On receiving a copy of this, my father wrote to William Elmore the letter already referred to, of March 18, 1901, which I give in full as closing the Crowder-Robson case.

"W. Elmore, Esq:

"Dear Sir—I received a pamphlet from the Ore Concentrating Syndicate on *Elmore's Process*.

"I must say I do not think that your son has acted fairly to Robson, or indeed to me; so far as I am concerned it does not matter, I am only too glad to find that you have at last tried the oil process, and found it to be a success.

"You will remember (as I have previously reminded you) I told you before you had spent 1s. 0d. on machinery that you could not concentrate that ore with water and I also offered you free of cost the use of the oil-concentrating plant *that your son saw* and that was at the time erected on the mine and which had done successful

work; your reply was 'please remove it as soon as possible.'

"On Dec. 10th, 1897, when I found that you were convinced that you had failed with the vanners and water, I wrote to your son the enclosed letter. Two years later, Jan. 1899, I heard that you were using oil, and had taken out a patent; *it is about as cool a piece of business as ever I heard of.*

"So far as I am personally concerned, I want no acknowledgement, but that your son should ignore Robson is not right; we spent about £2000 over the business and took out patents all over the world, France, Germany, the United States, Mexico, and all the Colonies.

"I am glad that you have at last adopted the method, and only regret that you did not do so when I first advised you.

"The first paragraph of the pamphlet struck me as being almost comical, as it is nearly verbatim the same that I wrote 5 or 6 years ago when bringing out our prospectus.

"I see your vanners only recovered 14.5%, less than half of what I obtained with jigs and buddles (on page 3). You can scarcely call it a '*novel process*' when you saw our plant erected on the mine when you bought it 5 years ago.

"On comparing your results from the oil, I find they are about the same as we obtained.

"Yours truly,

"S. CROWDER."

I enclose, Sir, copies of the original documents referred to. Possibly you will not be able to find space in your valuable paper for this necessarily long statement, but I feel assured, in any case, that with your well-known impartiality and desire for accuracy, you will sum up the evidence you now have before you in such a way that the true history of the flotation process will be known to the metallurgical world.

HEDLEY DAWN CROWDER.

El Oro, Mexico, January 27.

Patents and Successful Flotation

The Editor:

Sir—To the ordinary man the flotation controversy is becoming more thoroughly mixed than even the best practice of the art enjoins. Incidentally, it must be bringing to most of your readers the question to which you invited discussion with so little response some time ago, as to whether patents are worth while to anybody but lawyers.

I am one of those that believe there should be no patents, and that were there none the real inventor would receive a better reward for his invention than he does now. If there were no patent rights, invention would be just as prolific as now, but the inventor would have to trust to the honor of users for his reward, and I believe he would not be disappointed. In a well-known instance—the invention of the Glover tower, where

honor was relied on—I believe the inventor's claims were always recognized by honorable payment. Certain it is that the reward of valuable invention, under the present system, seldom reaches the real inventor, and it is obvious that such is going to be the case with flotation. But, *revenons à nos moutons*, are we not being muddled by the legal warfare into making puzzling a very simple matter? I recollect listening many years ago to a commencement address by a certain Senator to the students of a college in one of your central States, upon the subject 'Success,' in which, referring to great inventors and the anticipators, who were always raked up to decry their merits, he declared that the real inventor was the man who invented a thing so that "it kept invented." I think most of us will agree with the Senator.

Now, Sir, in your editorials and in most of the correspondence, the name of the inventor who 'kept' flotation 'invented' has been omitted. All are agreed as to where it was first "kept invented;" that is, at Broken Hill. Now, who kept it invented there? Most Australian on-lookers think of one man only, namely, Potter; but there can be no doubt about the answer if two names are included, namely, Elmore and Potter; they are the men who invented flotation and kept it invented at Broken Hill. You have given proper credit to Elmore, but what has become of poor old Potter? "Oh, he is dead," I hear somebody say. Yes, and he died poor and disappointed, and by that recompense qualified for the ranks of the immortal inventors of past ages. Some 11 or 12 years ago, visitors to Broken Hill were freely shown the Potter and Delprat processes in full work on a large scale. It was obvious that both processes were essentially the same, and it required an expert to detect differences in detail. At that time the Central mine was said to be experimenting with the granulation process, and visitors were refused admittance. What has happened since? The process has not altered in principle, or in appearance; to the non-expert eye the working and the results are the same. To the unbiased expert, as you and others have so often pointed out, the alterations, making for better work, were bound to be found out sooner or later by ordinary engineers accustomed to adapting new processes to varying conditions. That is all.

The clever men who have experimented and found out so many things, making the process cheaper and easier and of wider application, are entitled to honor. But that an obscure later explorer gave his name to the New World does not alter the fact that Columbus really discovered America or diminish his fame. You referred to the "flotation vendetta" in London. That is bad enough, but what is worse, and what began it, is the "patent grab" in Victoria. It is ancient gossip that the richest of the Broken Hill companies determined long ago to pay no royalties to anybody for treatment processes, and the company was so powerful and its officers so clever that it was left alone. Other smart* mining firms in Melbourne (than whom, an old Comstock miner told

*Smart is modern slang for 'legal but dishonorable.' See any dictionary.—AUTHOR.

me years ago, none are superior), as soon as it was seen that flotation, by the principle (not then understood) underlying the Elmore and Potter processes was going to solve the mixed sulphide problem of Broken Hill, set a host of clever chemists and metallurgists to work to find flaws in the patents, or modifications that could be patented and made bases for royalty claims and legal threats to enforce them. With a principle, which is so subversive of all our previous ideas of concentration, to be tried, it is no wonder they succeeded. The opportunities presented by the modern world to anybody who can obtain the legal monopoly of the right to utilize a hitherto unrecognized natural force, capable of world-wide profitable application, are such that everything which has followed since was a matter of course.

It is a sordid story, and adds force to those who believe the world would be morally better were there no patent laws.

AUSTRALIAN MINER.

Sydney, N. S. W., January 6.

Uneasy Miners at Adelaide

The Editor:

Sir—This place, Adelaide, an old mining district, is 12 miles south of Golconda, Nevada. At times during the past four or five years we have frequently noticed noises that sounded like the rumbling of a subterranean river. In 1912 I was doing assessment work on some claims in the Jungo desert, a mile and a half west of the Western Pacific railroad, and seven miles south of Jungo station. At that time I heard a noise that at first I thought to be an approaching automobile or a train. From that time on, and up to the present, these strange rumbling noises have continued, and have deceived many people as they did me.

In February 1915, while my partner and I were placer-mining a mile and a half from here, ashes from Mount Lassen, in California, fell all over this part of Nevada. At that particular time this curious buzzing noise was more noticeable than before. At one time we had an uneasy 'hunch' that something was going to happen and in the afternoon of that day, about 3 o'clock, we heard the noise I have referred to, and others heard it as well. Mrs. Playter, two miles from here, heard it and went to her front door to see who was coming in an 'auto.' The sound always seems to come from the west. At 3.30 p.m. that day we felt a distinct earth-shock, and another at 6 o'clock, while at supper. I then remarked to my partner that I would not be surprised if we got a good shaking before midnight, and we did. I shall never forget it! It was intensely cold that night, though the weather had been particularly fine for several days just before that. I stayed up from midnight until 5 a.m. and during that time I counted 350 shocks, then gave it up. Many people about here slept in their clothes for a week after that, and I was one of them. I believe these earthquakes had some connection with the eruptions of Mount Lassen.

We felt two earth-shocks on January 16, and addi-

tional shocks on January 17, 18, and 22. This afternoon, January 24, we felt a shock at 1 p.m. and another at 8:30. It is nothing new for this district. Ranchers say they felt shocks 30 years ago at Grass Valley, 25 miles south of here. Winter's ranch, 7 miles south of Adelaide, would be a good place for a seismograph. The family that used to live there abandoned the place because of the almost constant shaking of their house. The blasting in the old Adelaide mine, a quarter of a mile from here, shakes our house like an earthquake. This is a mining region but repeated earth-shocks do nothing toward insuring the safety of men working underground.

LORING HANSON.

Adelaide, Nevada, January 24.

[Earth-tremors are surficial. Men working in mines are safer than those on the surface. The earthquake of 1906 did no damage underground in mines.—EDITOR.]

Misfires

The Editor:

Sir—In your issue of February 3, Mr. E. F. Brooks, in replying to my discussion of his article on misfires, sets forth some ideas regarding the making of primers that I feel are open to question. Before discussing this particular point, I might call attention to the fact that the opinions held by men experienced in the loading and shooting of holes in various parts of the country are quite variable. It is not surprising, in view of the many grades and qualities of caps and fuse on the market, that this difference of opinion should exist. I believe that much good could be accomplished were it necessary for manufacturers of caps and fuse to submit their material to the Bureau of Mines for examination. The Bureau could establish a permissible list, the same as it does in the case of powder used in coal mines, thus guaranteeing to the public that the product offered for sale will come up to certain set requirements.

Mr. Brooks states that the method of making primers preferred by him is "to punch a diagonal hole in the powder near the end of the cartridge, insert the cap, and bend the fuse across the end of the powder, and insert in the hole, cap end first." This method doubtless is all right, provided the fuse is of a good grade and provided it is not cold. With poor fuse or with cold fuse I believe that this method will cause misfires. Obviously, it would not do to have rules to fit the different grades of fuse.

The methods of making primers submitted in my letter in your issue of January 6 were approved by the Bureau of Mines after an exhaustive series of tests, many of which were made at mines under conditions as encountered. Furthermore, these methods are approved by the leading powder manufacturers. Certainly such approval should be convincing. While in the employ of the Bureau of Mines, during a period of more than four years, I had occasion to investigate closely this subject in the most important metal-mining districts of the United States and thus became somewhat familiar with

the subject of misfires and their causes. In many mines, especially in the Lake Superior region, I found the use of the wooden punch for making a hole in the cartridge to be common. Also, I found that in many mines all primers were being made properly, the penalty for making them in any way except the one approved by the management being dismissal on the second offense.

Investigation in California discloses the fact that primers are commonly made by means of punching a hole in the end of the cartridge, inserting the capped fuse and bending the fuse back through 180°—and 25% of the miners killed in California during 1916 met their death as a result of misfires. Of course, this cannot all be blamed on the method of making primers, but with a percentage of fatalities from misfires that so far passes the record of other States, it appears that there is a mighty weak spot somewhere.

It is only fair to add that the bend occasioned by placing the capped fuse in the bottom of the cartridge is slightly greater than the bend necessary when a diagonal hole is punched "in the powder near the end of the cartridge." Thus, the method suggested by Mr. Brooks is somewhat of an improvement on the method referred to in the foregoing paragraphs. However, I would not recommend either of these methods for general use.

EDWIN HIGGINS.

San Francisco, February 5.

Sampling Small Lots

The Editor:

Sir—I have known for a long time that among shippers, and particularly small shippers, there is a very hazy idea of the methods of sampling ores used at the custom smelters, and in connection with the recent article, January 27, under 'Discussion,' by Mr. Lovejoys, I would like to make a few remarks that I believe would be a direct benefit to small shippers in general, who are unfamiliar with these methods.

In the case of the first lot mentioned, the fact that Mr. Lovejoys valued the lot at \$1100 for 380 lb. whereas an independent assayer gave \$10 per pound as his valuation shows something radically wrong. Surely no amount of 'perfumes' would account for such a difference. The Editor remarked in a recent interview that to find the number of raisins in a cake, you must eat the cake. This certainly applies to an ore containing coarse gold, and may account for the wide variation in assays between Mr. Lovejoys, the independent assayer, and the smelters. Since the smelters are aware of this fact, the invariable practice in handling small lots of such ores is to crush the entire lot so that it will pass a 30-mesh screen, weigh the metallic residue, if any, and assay it separately from the pulp. But Mr. Lovejoys says that no mention was made of 'metallics' in his settlement. Now, it does not necessarily follow that there will be metallic residues after grinding, even though the ore may contain coarse gold, as a very small amount of arsenic in the gold will render the metal so brittle that it will be ground up with

the ore and pass through the screen. Mr. Lovejoys states that the smelters gave the moisture content as 6.4%, and the ore was "dry and dusty." Now, there is a possibility of a mistake being made at the smelter, in view of which the shipper has the privilege of seeing the entire operation, or he may appoint a representative for that purpose. It is also a fact that ores, dusty and apparently dry, often do contain more than 6.4% moisture. The ore in question was hematite, and undoubtedly contained some limonite—the brown hematite that even in a perfectly dry state carries 14.4% moisture in the form of water of composition, a part of which will be driven off in the process of drying a sample. I might liken it to bluestone, which, though perfectly dry, will give water at ordinary room-temperature. I would advise anyone doubting this to weigh about two pounds of ore that he thinks is dry, leave it in the oven for 10 or 12 hours, and weigh it again, noting any difference in weight.

In regard to concentrate, a copper sulphide containing 8% moisture would be very damp on account of the fact that the moisture is practically all on the surface of the mineral particles, whereas an ore containing a like amount of moisture may barely show it on the surface—in fact, copper ores are notoriously deceptive as to moisture. I have seen many copper ores so dry that it was necessary to moisten before sampling, and these ores would show 10% moisture in their dry state.

I cannot believe that Mr. Lovejoys is in earnest about the suggestion of the "gentlemanly agreement"* between the smelters and the railroads. In conclusion, I wish to say that I am not connected in any way with the smelters, but, on the contrary, am engaged in representing the shippers at the smelters, so that I am perfectly familiar with the methods followed in sampling.

FRED. G. TYRREL.

San Francisco, January 29.

MEXICO is now once more practically on a hard-cash basis, but facing difficulties inasmuch as the hard cash necessary does not exist in the country. In 1912 silver was only used for payments under five pesos, larger amounts being paid in bank-bills. Since 1912 much silver has been exported by the Government for purchase of their requisites, and a good deal has been melted and exported by individuals. Furthermore, bank-bills no longer circulate, hence the scarcity of hard cash. It will be necessary either to bring in and use American money (which, of course, is not strictly legal tender, although it is extensively used along the border and coast districts), or for the Government to get out some new guaranteed bills, or make arrangements for the use of the old bank-bills. Thus all paper issues for the last two or three years have successively gone to the wall, none of them having been redeemed and with little probability of their redemption. This may be the best way to get rid of this obligation.

*The statement made was that "shipments made through the express company invariably realized nearer our assay than did shipments made by freight."

Grand Forks and Phoenix, British Columbia

By T. A. Rickard

Among the important American enterprises established in British Columbia is the Granby Consolidated Smelting, Mining & Power Co., which owes its name to the town of Granby, in Quebec, that having been the home of S. H. C. Miner, who organized the company, in conjunction with J. P. Graves, of Spokane, in March 1901. Subsequently the American Metal Co. became a prom-

MAP OF PART OF BRITISH COLUMBIA.

inent factor in the business and for several years the president of the metal company, the late Jacob Lange-loth, was president of the Granby Consolidated. This company was formed to exploit the Knob Hill and Old Ironsides mines at Phoenix, in the Osoyoos district, and to operate the smelter that was built at Grand Forks. A. B. W. Hodges was local manager and W. Yolen Williams was consulting engineer for many years. To them may be credited the successful development of the undertaking. Both have now retired, F. M. Sylvester being managing director and vice-president. To Mr. Hodges is due special recognition for the design and equipment of the smelter at Grand Forks.

I went there on a broiling day when the conical slag-heaps and the cloud of smelter-smoke amid the sunburnt hills composed a scene suggesting volcanic activity. The two black cones of slag constitute the characteristic feature of the picture. They represent the refuse from the smelting of 12,000,000 tons of ore. The bigger one contains 2,000,000 tons. As the slag flows from the blast-furnaces it is granulated at four places by impact with a jet of water, which washes it into a bin outside. Here it is de-watered and then conveyed on six belts working in tandem, the total length being 1600 ft. The foremost belt is telescopic, so that it can be pushed forward as desired. This equipment has a capacity of 9000 tons per day. The other dump and its belt-conveyor serve as an auxiliary discharge.

Two railway lines, those of the Canadian Pacific and

the Great Northern, enter the smelter-yard. The cars, as they arrive loaded with ore from Phoenix, or from elsewhere, are emptied into bins arranged in series along five tracks. The first of these serves the sampler and the other four supply the furnaces, two tracks for coke alternating with two for ore. Both railways go to the copper mines at Phoenix and both touch Crow's Nest Pass, from which comes the coke. About 1000 tons of custom ore is received monthly, chiefly from Republic, in the adjoining State of Washington, but some ore comes also from mines in Idaho and Montana, besides occasional shipments from British Columbian districts. Eight blast-furnaces and three converters are in use, smelting 3500 tons of ore daily and employing 195 men altogether. A train of three charge-cars feeds each pair of furnaces alternately. The coke is charged separately, at the rate of 400 to 450 tons daily. As much as 550 tons of ore has been put through a single furnace in one day. The small number of men employed is noticeable. The wage-scale is based on a \$3 rate for common labor, but the men now receive \$1.25 per day more on account of the higher price of copper. The employees are a good class of men, many of them owning farms in the adjacent Kettle valley. When the European war began, the plant

ONE OF THE SLAG-HEAPS, SHOWING CONVEYOR SYSTEM.

was shut-down for five months, owing to the collapse of the metal market. The men accepted a 25% reduction in their wages, so that the minimum pay for awhile was \$2.25. Now they are recompensed. The labor employed is mixed: Canadian, British, and American. Real foreigners are rare on the pay-roll.

The three charge-cars enter the blast-furnace, a rail three feet above the track receiving the small subsidiary wheels placed along the top length of the cars so as to empty them. This self-dumping charge-car was de-

signed and patented by Mr. Hodges, when manager, in 1905. The system of charging was worked out by Messrs. Hodges and Williams. The furnace is set at right angles to the line of front. At Anyox the furnaces are lengthwise of each other. The water-jackets

as already described. The lining of the conduit that carries the granulated slag is made of slabs of slag, 18 by 24 inches, and 3 inches thick, reinforced by a sheet of 'trussit metal,' a herring-bone metal lath, the idea for which came from Anaconda. This lining lasts for two

THE GRANBY SMELTER, AT GRAND FORKS, B. C.

THE CONVEYERS, SLAG-POTS, AND COPPER-MOULDS.

are in two tiers, so that they extend to 12 ft. above the base-plate. Each furnace has not less than three settlers; and as a pair of furnaces may have two settlers in common, the slag passes through five settlers. The settlers are made in the shape of the frustum of a cone so as to render the 'sow,' or mass of low-grade matte, easily detachable when it has chilled. The slag is granulated,

years, as against the four months' life of the various steel linings that have been tried. The side and bottom 'slabs' (or bricks of slag) are interchangeable and are easily replaced when worn out. When running at full blast, the consumption of water is 4500 gal. per minute, all of it being discharged at the boiling-point.

On the charge-floor 12 men are employed when smelt-

ing at full capacity; on the furnace-floor 10 are required, including two helpers. The electric crane saves a lot of manual labor. This equipment consists of two 10-ton cranes in the furnace-room, connecting with a 40-ton crane in the converter department. Electric power comes at 60,000 volts and is transformed to 440 volts.

The converter department contains 3 stands and 10 shells. Five men are employed. At the time of my visit I saw three converters in different stages of activity; one converter was in blast, shooting its gases up the hood noisily; another was in the act of pouring slag, being tilted so as to discharge into a 5-ton pot; the third converter was pouring blister copper into moulds, each holding 200 lb. of 98½% metal. After the slag had drained out of the second converter, a scoop or 'boat' was lowered and tilted from the crane, so as to feed the quartz ore needed to supply the requisite silica. The slag-pot was lifted by the crane and taken to the tilting-cradle in front of a pan-conveyor. Then the pot, now lined with slag, was used to convey matte, the crane taking the pot to the blast-furnace, where it was filled with material to be 'converted.' When the shell of slag lining the pot becomes too thick, it is discharged on the ground and broken into small fragments by dropping a big steel ball upon it. Then the pot is given a clay wash and resumes its round of duty.

While standing observant I saw a surgical operation performed on the throat of the first converter. This had become clogged with an accretion of matte and slag, which had to be removed, otherwise the outlet for the gases of combustion would be insufficient and the metallurgical process would stop. Therefore this accretion was removed by aid of a large forged-steel hook, the point of which is capable of being detached and sharpened by the blacksmith. This hook is operated by the 40-ton crane, being lowered into the mouth of the converter so as to pull out the accretion, like a dentist's forceps, and drop the clotted mass into the converter for re-fusion. Greek and Austrian magnesite is used to line the converters.

The slag from the converters is removed on a pan-conveyor discharging into a bin from which railroad-cars are loaded, to discharge their load in turn into the bins at the back of the smelter. In falling from the conveyor, the slag shatters itself sufficiently to render any crusher unnecessary. Each pan holds 100 lb., the capacity of the conveyor being 250 tons per 24 hours, or more than is required. The blast-furnace slag is maintained at about 46% silica, the iron and lime adjusting themselves automatically at 15% iron and 21% lime. Ten tons of ore is charged at a time, from the three cars, together with 13.17% coke—that was the average in 1915. Each furnace smelts 400 to 500 tons per day, so that theoretically a ton takes 1/45th of 24 hours or about half an hour, but the metallurgist does not look at it that way because he knows that the ore remains in the furnace until it is smelted. Chunks of refractory ore may linger in the cooler part of the furnace for a whole week.

The ore from Phoenix is practically self-fluxing. No roasting is done. The slag that goes to the dump contains 0.21% copper. The cost of smelting and converting at Grand Forks was \$1.23 per ton of ore in the year ended June 30, 1916.

One smoke-stack bears the date 1900; the other, 1905. These were the years in which the plant was built and then enlarged. The original plant, built in 1899 and blown-in during August 1900, was intended to treat the ore from the company's mines at Phoenix; it consisted of two small (44 by 160 in.) blast-furnaces, and, as the ore was both low-grade and self-fluxing, the plant could be made simple in design with due regard for the economical handling of ore, coke, flue-dust, matte, slag, and metal. After a few months of operation had shown that a small profit could be made on each ton of ore it became only a question of large tonnage to make the business profitable on a much larger scale. In the following two years two furnaces and three converter-stands were added; in 1904, two more furnaces; in 1905 two more, 48 by 213 inches. In this year the length of the smaller furnaces was increased to 266½ inches and the old converters were replaced by three new ones, 84 by 126 inches.

During 1916 the coal strike in District No. 18, which includes the coal-fields of eastern British Columbia and the whole of Alberta, interfered with the supply of coke. Between August 2 and August 10 five thousand men were idle. Then an accident in the No. 3 mine at Michel caused the death of 12 men. The accident is supposed to have been due to lightning entering the mine and exploding the gas. The interruption to the supply of fuel compelled the management to reduce the work of the furnaces to one-half, but the shipment of matte from Anyox kept the converters busy and enabled the production of copper to be maintained at normal, as explained to me by W. B. Bishop, the smelter superintendent, to whom I am indebted for many courtesies. His chief, W. A. Williams, who is superintendent of smelters, was at Anyox at the time of my visit. Under the direction of Mr. Sylvester, the Granby Consolidated has expanded its activities and increased its profit by the acquisition of the Hidden Creek mine, on Observatory inlet, on the coast and about 600 miles north of Vancouver. This big copper deposit was acquired from M. K. Rodgers and associates in 1912, and in 1914 the first unit of the new smelter at Anyox, two miles from the Hidden Creek mine, went into operation. The mine has been developed to the point where 18,000,000 tons of 2½% copper ore is assured and the capacity of the smelter is now such as to treat 3000 tons daily. During 1916 the converters were unable to cope with the increased output of matte, so that a considerable tonnage of it went to Grand Forks. The blister copper, both from Anyox and Grand Forks, is shipped for refining to the Nichols Copper Co. in the State of New York.*

To Mr. Hodges I am indebted for the following notes:

*A description of the metallurgical operations at Anyox, taken from the company's annual report, appeared in our issue of November 25, 1916.

FIG. 1. CROSS-SECTION OF THE PHOENIX DISTRICT.

"An article published in your issue of February 13, 1909, gives a good idea as to the smelting-plant in December 1908. I might, however, bring out certain points wherein the Granby smelter is different from other plants; these are as follows: position of blast-furnaces, charging-system, settling blast-furnace slag, handling of the slag.

"Of course, you noticed that the eight furnaces were all set parallel to one another and not end to end as is now the practice in all new plants; this I decided to do at the start in order to be better adapted to a certain mechanical furnace-charging device that I had invented and wanted to install at the beginning. At this time you must remember that in almost all of the copper-smelting plants the furnaces were fed by hand.

"The method of charging is peculiar to the Granby plant; it is adapted to furnaces set parallel to one another and is only used at one other smelter, namely, at

certain spot, and at the same time put the regular charge in the rest of the furnace.

"The only other mechanical feed that is better than this was invented some years ago by W. H. Freeland, but his is only adapted to furnaces that have an unobstructed charging-floor, such as are not built nowadays. A good description of Mr. Freeland's system is found in an article by David H. Browne, published in the Canadian Mining Institute bulletin for November 1916. As a rule, in copper plants the furnaces are placed end to end and fed from the side by cars that roll or dump or slide the charge in, thus upsetting any pre-arrangement.

"The blast-furnace slag, after being granulated by water is run on a belt and elevated to a great height, and I think that this is the only copper smelter where this method is used. This scheme was adopted after I left the plant for South America in 1910; before that we used to handle the slag hot in large slag-pots, which were hauled to the dump by small steam-locomotives, but as about all the available space became filled up and the haul became too long, the belt-elevator was put in.

"You probably noticed that there were three small settlers before the furnaces instead of one large 18-ft. settler. The reason that I adopted the smaller size was on account of the very high silica in the charge; a high percentage of coke was necessary, and this condition formed a comparatively large amount of what the foreman called 'metallies,' which built up the bottom of the settlers rapidly; therefore

FIG. 2. A FAULT.

Trail, B. C. The particular advantage of this system is that the charge-cars run right in the end of the furnaces and the charge is dropped, without altering, but to a very small extent, its previous arrangement, thus enabling one to place the coke and fine ore along the jackets, and the coarse ore in the centre of the furnace, or leave out charging certain parts, or put a special charge in a

FIG. 3. FAULTING OF AN OREBODY.

when a small settler became filled up to such an extent that it was not efficient, an electric crane picked up the whole thing and put a new one in its place in a few minutes, whereas if a large one had been used the furnace would have to be shut-down while repairs were being made. On account of the little settler being too small to properly settle the matte out of the slag a second settler was added and afterward a third, which I really think is more efficient than one big one.

"Another thing you probably noticed was that the air for the blast-furnaces came from blowers situated at each end of the plant, and also that the flue-chamber was divided in the middle, the gases and flue-dust from four furnaces going to a separate chamber and stack. This is not modern practice, but was brought about by increasing the capacity of the plant from two furnaces of 800 tons per day to eight furnaces of 3500 daily capacity without building an entirely new plant and without losing a furnace-day, and at the same time keeping the smelting-cost down to the lowest figure."

Phoenix is 9 miles, as the crow flies, from Grand Forks, but the wagon-road is 15 miles long and the railroad 26 miles, the difference of altitude being 2500 feet. The Granby Consolidated controls nearly all of the productive ground remaining at Phoenix, most of the outside properties having been worked to a finish.

The journey in an automobile along an excellent road is most pleasant, giving a view first of the smiling valley and then of the forested hills. On arrival we went to the Gold Drop mine, and from the dump viewed the panorama of mountains. Due east is the peak called Old Glory, near Rossland, and north the range overlooking lake Christina and the Arrow waterway. The International boundary—which I do not claim to have seen—is only $6\frac{1}{2}$ miles away. At the foot of the dump were signs of the Snowshoe workings, owned formerly by the Snowshoe Gold & Copper Mining Co., of London, and leased for several years to the Consolidated Mining & Smelting Co. of Canada before being purchased by the Granby company three years ago. The ore was low-grade and the tonnage insufficient to warrant the erection of a smelter by the English company.

The main orebodies of the Granby properties, notably the Knob Hill and Ironsides mines, have been found along the western foot-wall of the 'jasperoid' while the Gold Drop workings are on the eastern side of the hill, also on the foot-wall. The geology of the ore deposits has been described and explained by O. E. LeRoy in Memoir No. 21 of the Canadian Geological Survey. The accompanying cross-sections are taken from that memoir.

The accompanying section (Fig. 1) of the Phoenix district is taken from Mr. Le Roy's report, but a slight alteration has been made at the east end of the section in accordance with the evidence obtained in later exploration underground.

The Phoenix orebodies are typical replacements of limestone at or near the contact with an igneous rock. In this locality the limestone is the Brooklyn formation,

probably of Carboniferous age. The igneous rock that produced the contact metamorphism has been eroded, but there is reason to infer that it was some off-shoot from the batholith of grano-diorite, such as the syenite-porphry, dikes of which cut the mineralized zone.

The orebodies in the limestone have a flatly lenticular shape occupying depressions having usually a floor of 'jasperoid,' although unaltered limestone or tuff may also form the base. The jasperoid, which overlies the tuff, is a chalcedonic agglomerate marking lines of brecciation in the limestone or in calcareous tuff. It forms the so-called foot-wall of the principal orebodies and passes upward into a metamorphosed limestone, called 'gangue,' composed of epidote, garnet, quartz, calcite, and chlorite. Magnetite is found both within the ore and bordering it. Waldemar Lindgren, who examined thin sections of the ore for S. F. Emmons several years ago, stated then† that the specimens "showed pretty clearly that a metasomatic replacement has occurred, during which a granular limestone has been converted into amphibolitic rock, and that simultaneously, or almost simultaneously, magnetite and sulphides have been developed." Emmons himself had visited Phoenix and remarked upon the curious association of magnetite with the sulphides of iron and copper. He noted the lack of fracture-planes or walls enclosing the orebodies, or even defining their direction, emphasizing the fact that the ore grades off insensibly into rock that is not 'ore,' owing to its poverty in copper. The valuable mineral is chalcopyrite in a rock that carries 1.25% of copper and about \$1 per ton in the two precious metals.

The orebodies range in size from lenses 5 ft. thick and 50 ft. long to masses like that of the Knob Hill and Ironsides mines, 125 ft. thick, 900 ft. wide, and 2500 ft. long. The first ore was traced underground from outcrops, but the larger exploration of the district was done by aid of diamond-drilling, which furnished the information on which the broad outlines of the ore-bearing limestone could be ascertained with an accuracy sufficient to guide systematic development. By such methods the mineralized zone has been so thoroughly prospected that the probabilities of finding more ore have been exhausted and it has become recognized that the life of the mines remaining active is limited to about three years more on the present shipping basis. It will, however, be impossible to work at all points simultaneously and the life of the district therefore is likely to be prolonged.

In March 1910 the shareholders of the Granby Consolidated were shocked by the publication of a report made by Otto Sussmann. He stated that the reserve of ore amounted to 6,826,920 tons averaging 1.25% copper. A great deal of unnecessary fuss was made over this report, for Dr. Sussmann had merely emphasized facts that should have been made clear previously in the company's annual reports. The definite limits of the ore-bearing ground had been ascertained by the Geological Survey, the members of which had been quite frank with the company's engineers. Mr. LeRoy had

†'Genesis of Ore Deposits.' Trans. A. I. M. E., page 761.

examined the district in 1908 and re-visited it during 1909, so that the main outlines of the local geology were well known early in 1910. In the six years since, that

Campbell and the other engineers on the staff acknowledge gratefully the friendly aid of Mr. LeRoy and his fellow-geologists, who before they left the district, in 1910, gave the management the use of the preliminary maps. The geologic data thus obtained have proved of great assistance in prospecting the ground.

The connection between orebodies and fissures is not often obvious and the suggestion has been made that the limestone was impregnated by solutions that found their way through joints and minor fractures. On the other hand, the foot-wall, which is so well defined in the Electric Shovel pit, looks as if it might have served as a channel of circulation. This seems to be Mr. LeRoy's opinion for he states that "the fissures have undoubtedly been the important factor in the deposition of the ore."

At present 18% of the output comes from surficial mining. The largest open-cut is over 2000 ft. long and has a maximum width of 400 ft. Excavation is done by use of a Bucyrus No. 40R electric shovel, provided with a $1\frac{1}{2}$ -cu. yd. dipper, and a 'jack' on each side to brace the machine when lifting on the opposite side. The cars contain 10 tons each when heaped, the nominal capacity being 7 tons. They are equipped with the automatic side-dumping subsidiary wheels, as shown in the accompanying photographs. This car is known as the Granby, having been designed by the engineers of this company. It is used in many of the British Columbian mines, notably at Anyox and in the Britannia mine.

These ore deposits have been a great source of wealth, despite their low tenor, because they have been self-fluxing. My friend Ralph Stokes, now "doing his bit" with notable success "somewhere in France" visited Phoenix in 1907 and in his book he gave the typical analysis:

	%		%
Lime	18—22	Alumina	6—7
Silica	38—40	Magnesia	6—7
Iron	10—14	Sulphur	2—4.5

He also remarked[‡] on the tendency to an increase of silica in depth, but Mr. Campbell is of a different opinion. In the light of the later evidence of deeper workings he is able to state that the silica seems to be "pretty uniformly distributed." With the exception of the garnet, the concentration of any one mineral is not characteristic of any particular part of the orebody.

NICKEL mining is of first importance in Ontario. In 1915 the nickel contained in Sudbury matte amounted to 34,039 tons, valued at \$17,019,500. In 1915 the output was 42,000 tons, worth \$21,000,000. During 1916 both of the operating companies, the Canadian Copper Co. and the Mond Nickel Co., worked to their fullest capacity their mines and smelters in Ontario, as well as their refineries, one of which is in New Jersey, the other in Wales. Another source of nickel in Canada is the nickel oxide obtained by the refineries from the ore of the Cobalt district. A little metallic nickel was obtained elsewhere during the year, but production was relatively unimportant.

2. BACK VIEW.

3. SIDE VIEW.

is, from July 1, 1910, to July 1, 1916, the output of ore from the Granby Consolidated mines at Phoenix has been 5,853,164 tons averaging 1.1% copper and there remains still 3,610,000 tons estimated to contain 1% copper, with 75 cents per ton in gold and silver. C. M.

The Emerald Mines of Colombia

The emerald is a gem that rivals the diamond in beauty and in value. It is not nearly as hard as the diamond, in this respect ranking with topaz, but flawless stones of good color are highly esteemed. The principal emerald mines of the world are in Colombia about 80 miles north-west of the city of Bogota, in an almost inaccessible part of the Andes, at the head of the Orinoco river. These mines were worked centuries ago—long before the conquest. The Spaniards operated the mines with vigor, impressing the Chibcha Indians into their service. At that time the natives placed their treasures beyond the reach of the *conquistadores*, so says the story, by throwing both gold and gems into the lakes. One of these bodies of water was Lake Gutavita, which is said to be the place of the fabled El Dorado—the gilded man—and from which came the many traditions of the 'Land of El Dorado,' so eagerly sought, though vainly, in the 16th century.

The story of El Dorado can be told briefly: The Indians were accustomed to celebrate the accession of a tribal chieftain with elaborate ceremonies, during the course of which the young chief, smeared with a thin layer of clay and then covered with a film of beaten or dust-like gold, proceeded on a raft to the centre of the lake, and there, as a sacrifice to the gods, threw overboard a great quantity of gold and emeralds.

The emerald deposits, after a long search, were discovered by the Spaniards, near the crest of the Andes. The Indians had worked them during each rainy season, breaking down the gem-bearing ground with wooden bars, assisted in the operation by small streams of water delivered from ditches. The Spaniards found open pits and dumps of waste-rock so large as to make it evident that work had been in progress for a long time, probably for centuries. At first they adopted no systematic method, although they obtained a rich reward from such careless work as they did. Later, however, realizing the great value of the mines, the Spaniards took complete possession, and it is said that 1200 Indians were employed there in 1565. Four times a year shipments of the precious stones were made to Spain and for 150 years mining continued under Spanish ownership, but toward the last the expense became greater than the value of the product and the mines were closed down by order of Charles II.

Soon thereafter the luxuriant tropical vegetation covered the pits and the mines were lost to all but tradition. It remained for an enterprising Colombian, Francisco Restrepo, to re-discover one of the ancient workings, guided by a description in an old Spanish tome and a parchment map. But these deposits appear to have been exhausted and proved unprofitable. Exploration by the early Spaniards, however, had resulted in the finding of other emerald mines that were being secretly worked by the natives. Among these the deposits at Muzo were the most important, but still other deposits were dis-

covered, notably those at Coscuez, north-west of Muzo. At the Coscuez mines some of the operations were underground, and it is stated that at one time 300 Indians were killed by the caving of the workings, this accident causing work to be suspended for a long time. Work was resumed early in the 19th century, but these mines, too, were abandoned and soon were overgrown by a dense growth of jungle. They were re-discovered a few years ago, and when work is resumed there it will be under the auspices of the Colombian government, which controls the emerald mines of the republic.

The emerald mines of Muzo are thus described by Joseph E. Pogue, of the Northwestern University.* "The mines consist of a series of some eight large open-cuts, which lie closely grouped on the steep slopes of a densely-wooded mountain. From a little distance the main workings seem to form a huge funnel-shaped depression, which appears in striking contrast to the long velvety slopes of green. Entering this crater-like opening through a narrow canyon below, or looking down upon it from its rim above, one sees in detail, the individual cuts as sloping banks of terraces resembling giant stairways. Across these working-faces, which consist of folded and contorted beds of coal-black limestone and shale, stretches an irregular network of white threads, gleaming in the tropical sun like zigzag lightning flashes in a field of black. These are the calcite veins which carry here and there, but none too abundantly, small cavities or nests lined with tiny crystals of emerald and associated minerals.

"The emeralds, when freed from their matrix are seen to be small six-sided prisms of rich green color, ranging from the size of a man's thumb to microscopic dimensions. The flaws, or internal cracks, characteristic of these as of all other emeralds, are not always present in the freshly mined stones, but if not they almost invariably develop soon after the specimen is removed from the inclosing rock, a result presumably caused by a strained condition of crystallization. Recently a few remarkable crystals have been found showing a tapering hexagonal core and six-rayed star of carbon dust.

"The mines up to 1913, when operations ceased, have been worked in a rather simple manner by Indian laborers or peons, breaking down the friable emerald-bearing rock with long iron crow-bars and picking out the emerald veins by hand. A regular attack in this manner along definite lines gives rise to the horizontal sets of benches or terraces so characteristic of recent workings. It would seem that modern types of mining machinery, such as the steam-shovel, might be profitably introduced; yet, so fragile are the emerald crystals that the operations may have to continue to rely largely on individual effort.

"From the end of the 16th century to 1830 practically all the emeralds that came upon the European market were obtained from Colombia; and such is the source of probably the majority of emeralds in circulation today, outside of the Orient."

FIG. 1 AND 2. LOADING AND DISCHARGE STATIONS.

The Spanish Peak Aerial Tramway

By J. A. Kitts

Aerial tramways, as designed and built today, represent the application of sound engineering principles, based on experience derived from the design, construction, and operation of several thousand lines, having a total length of many thousand miles. They have become recognized as an economical and practicable means of transportation. They are especially adapted to mountainous country, and solve the problem of transportation to and from territory that is economically inaccessible by surface lines.

Aerial tramways have been built for many purposes, as indicated in the following list of notable lines:

Company and locality	Length, ft.	Capacity per hour	Material
Bethlehem Steel, Bethlehem, Pa.....	1,900	200 tons	limestone
O'Brien Munitions, Renfrew, Ont.....	900	2½ "	cotton in cans
Carnegie Steel, New Castle, Pa.....	3,700	150 "	flue dust
Tacoma Smelting, Tacoma, Wash.....	2,850	100 "	ore
Spanish Peak Lumber, Quincy, Cal.....	27,200	15 "	lumber
Am. Smelting & Refining, Christmas, Ariz...	7,350	40 "	ore
Con. Interstate-Callahan, Wallace, Idaho....	10,475	25 "	zinc concentrate
Butters-Divisadero, San Salvador, C. A.....	11,750	20 "	ore
Baker Mines, Cornucopia, Ore.....	5,500	15 "	"
American Zinc, Mascot, Tenn.....	1,900	60 "	"
Kennecott Mines, Kennecott, Alaska.....	15,150	25 "	"
Cassidy Coal, Curwensville, Pa.....	4,635	20 "	coal
Spring Canyon Coal, Provo, Utah.....	2,900	250 "	"
McKinley-Darragh, Cobalt, Ont.....	4,800	5 "	ore
Tomboy Gold Mines, Telluride, Colo.....	6,800	15 "	concentrate
Saline Valley Salt, Bishop, Cal.....	69,925	20 "	salt

The Spanish Peak aerial tramway is unique in that it was designed and built for the purpose of carrying sawed lumber for commercial purposes direct from the saw-mill and yard over a mountain range to a connecting railroad. This development is of particular interest since our forests are largely confined to rugged and mountainous country. The lumber company's property is at Spanish Ranch, seven miles west of

Quincy, Plumas county, California, and about five miles by air-line from the Western Pacific railway. The easiest surface-line route from Spanish Ranch would be by way of Spanish creek, connecting with the Quincy Western railroad at Quincy. Spanish creek, however, is so tortuous and the general topography is so precipitous as to make it impossible to construct any type of surface-line for a reasonable amount of money.

The aerial tramway was selected as the only feasible means of carrying lumber from this territory, on a commercial basis.

The saw-mill and drying-yard of the company are at Spanish Ranch, and the manufacturing plant and storage-yard are at Grays Flat, on the Western Pacific railway. The tramway connects these two points, and is a little over five miles long. It has a normal capacity of 15 tons or 10,000 ft. B.M. per hour, when running at the rate of 414 ft. per minute. This capacity may be increased somewhat by increasing the speed of the hauling-rope. The discharge-terminal is 890 ft. lower than the loading-terminal, and the tramway, when running under normal load, develops 10 hp. To utilize this power, a 15-kw.

generator has been connected to the control-unit, the power generated being used for lighting and other purposes.

A maximum of 20 hp. is required when loading the line, and 15 hp. is required to brake the line when stripping. Water-power under 225-ft. head is used. The power-braking device (Fig. 4) consists of two Pelton water-motors, mounted on a concrete foundation at the

loading-terminal. These motors are standard 24-in. units with the two shafts connected by a rigid coupling, which also serves as a double pulley for driving the two governor oil-pumps. The motors are connected in opposition. The governors are so adjusted that when the speed of the tramway drops below normal, water is admitted to the power-wheel. Should the speed go above normal (the usual tendency) water is admitted into the brake-wheel. As this motor is set in opposition to the power motor, it is obvious that the jet, instead of driving the runner, will be struck by the buckets rotating against the jet. In this manner the excess power of the tramway is absorbed. Direct-motion oil-type governors are used, the pistons of the servo-motors being mounted on an extension of the needle-stems. The speed is kept between the limits of 5% above or below normal speed.

The number of supports required by an aerial tramway depends upon the length and, also, largely upon the nature of the profile of the line. To insure the wearing life of the track-cables, the vertical angles, or curvature, must be limited. Supports of the tower type are ordinarily equipped with cast-iron saddles in which the cables rest and suitable rollers for supporting the traction-rope. In the case of long spans, or where the bend in the track-cable would be excessive with a rigid saddle, so-called compensating saddles are used, each consisting of a pair of saddles mounted on an oscillating beam, which permits the passage of the carriers without undue bending of the cable. Where sudden downward bends occur, supports are used consisting of a series of bents in close proximity, each equipped with saddles, thus dividing the total large bend into a number of slight bends. Where the bend is comparatively great, as in the case of sharp ridges, supporting structures are used in which the cables are overlaid with rails.

At one point in the Spanish Peak line a horizontal bend of 7° is made by means of a couple of supports of special design, the carriers passing through these without detaching from the traction-rope, thus avoiding the usual cumbersome and expensive structure equipped with large sheaves for deflecting the traction-rope, and requiring an attendant to pass the carriers.

There are 65 structures on this line comprising 48 simple tower-supports, as shown in Fig. 3, varying in height from 12 to 55 ft., 8 of which are equipped with compensating saddles, 2 simple angle-stations, 2 two-bent supports, 2 four-bent supports, 4 curved-rail stations, 2 double-anchorage stations, 2 double-tension stations, as shown in the background of Fig. 3, 1 anchorage and tension station, and 2 terminal stations (Fig. 1 and 2). The loading-terminal is also an anchorage-station for the track-cables, and the discharge-terminal is a tension-station for both track and hauling cables. These structures are of timber on concrete foundations. The quantity of timber used was 250,000 ft. B.M., and the quantity of concrete 600 cu. yd. The structure members are all bolted together, and the posts and struts are fastened to the concrete founda-

tions by angle-clips placed on anchor-bolts, these clips being bolted to the timber. The structure members were completely framed and bored at the nearest terminal station, hauled to the site and erected. The foundations are mostly in earth. Four towers and two other structures are founded on rock, a partly decomposed, badly broken, and fissured slate. The slopes were steep, as shown in Fig. 3. The discharge-terminal foundations are in river-gravel. In the design of the foundations, particular attention was paid to local conditions.

The average distance between supports is 410 ft., the maximum span being 2810 ft. The track-cables are of the American Steel & Wire Co. lock-coil construction. These cables are $1\frac{1}{2}$ -in. and $\frac{3}{4}$ -in. diam. on the loaded and empty sides, respectively. A $\frac{5}{8}$ -in. diam., 6 by 7 Lang-lay cable is used for the traction rope. The working tension on the track-cables is 30,000 lb. per sq. in. of metal section. The track-cables are divided into six sections of one mile or less in length, each section being anchored at one end and weighted at the other, a constant tension being maintained in this manner. The traction-rope is a continuous loop over 10 miles long.

The carriers are specially designed for carrying lumber, the essential requirements being that the slings for holding the packages are simple and easily placed, and the loads easily dropped. It was also necessary that the lumber be protected from damage by these slings. The carrier consists of a two-wheel carriage, a rigid hanger pivoted to the carriage to allow free movement in a longitudinal direction, two chains suspended from the hanger and pivoted to allow movement in a transverse direction, these chains in turn suspending a channel-iron bolster. Guards of angle-iron section are placed on the chains, so as to protect the lumber from marring, these guards being free to move on the chain to accommodate a load from 6 to 16 in. high. The chain on one side is fastened to the channel iron-bolster, while that on the other side is made to detach from the bolster by means of a simple catch or latch. The horizontal component of the weight of the lumber, acting through the chains, serves as the only gripping device for holding the load. Two carriers are used for each load. These carriers are independent of each other and are provided with grips for attaching to the traction-rope. The Webber grip is used for this purpose. There are 164 of these carriers, also four 8-cu. ft. ore-buckets and a track-cable oiler. This is about twice as many carriers as would be put on the line at one time.

The packages may be made to contain from 300 to 700 ft. B.M. with almost any end-area dimension up to 12 by 32 in. or 16 by 30 in., and in lengths up to 32 ft. or more (see Fig. 5). The normal package is 512 ft. B.M. These packages are sent out every three minutes, making them 1242 ft. apart on the line.

Eight men are used in the operation of the line, two loaders, two dispatchers, two linemen, and two unloaders. One dispatcher attends to the machinery and equipment and the other keeps the records of loads dispatched, etc. The tramway is equipped with a

FIG. 3 AND 5. TOWER-SUPPORT AND PACKAGE OF LUMBER.

double or metallic-circuit telephone line, telephones being placed at the two terminals and at the principal stations along the line. This telephone system is used for signaling as well as for inter-communication. The telephones are of the Stromberg & Carlson make, with 2500-ohm ringers.

Actual construction required eight and one-half months. The profile survey of the line was completed in October 1915. The position of the structures was

BRAKING DEVICE.

then determined, and the survey of the sites was completed in December. Clearing right-of-way was started in October 1915, and practically completed, except for the burning of 'slashings,' in December 1915. The underbrush and small growth was cleared 25 ft. on each side of the centre-line, and large trees were cleared 10 ft. on each side. All dead, leaning, and otherwise unsafe trees, which could reach the line in falling, were felled. Most of the tower heads were framed between October 1 and December 15. The work was suspended

for the winter December 15 and was resumed April 1. Active construction was started May 1, and the line was put in operation September 30, 1916. The design of the special structures and foundations was completed between December 15 and May 1. The dimensions of the 48 tower-substructures and the offset of piers were determined in the field-office; the elevations of the piers were determined graphically from the cable elevations and the cross-sections of the ground; and the offset of piers, lengths of posts, girts, etc., was computed according to the type of structure and the local conditions.

The line was designed and built under the direction of F. C. Carstarphen, tramway engineer for the American Steel & Wire Co. of Trenton, New Jersey. The company furnished the cables, equipment, and all metal parts, with the exception of the power and control unit, which was furnished by the Pelton Water Wheel Co. T. J. Murphy, field engineer for the company, had charge of the erection of cables. I was field engineer in charge for the American Steel & Wire Co., and superintendent of construction for the Spanish Peak Lumber Co. L. T. Hays, F. S. Winslow, and W. B. Sawyer, Jr., of the United States Steel Products Co., of San Francisco, were concerned in the sale of the tramway and took an active interest in the solution of the various field problems. The officials of the Spanish Peak Lumber Co. are O. C. Haslett, president, and D. L. Bliss, Jr., general manager.

CARBONS for diamond-drilling should be selected with care. Those stones, which when examined under a strong glass, have a firm compact appearance, being free from checks, generally prove to be the best. Stones which have a sandy or spongy texture will be found to wear rapidly by abrasion. A set of stones of this latter description was tried and the cost of drilling, for diamonds alone, ran up to \$15 per foot. The ground could be driven by hand for \$4 per foot, so diamond-drilling was promptly stopped until suitable carbons could be obtained.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

COLEMANITE contains 50.9% of boric acid, 27.2% of lime, and 21.9% water.

EXPORT DUTY on tin ore from the Federated Malay States averages 12% of its gross value.

DRILLING by tripod types of machines at Santa Rita, New Mexico, costs from 32 to 46 cents per foot.

DRILLS should not be allowed to become less than standard gauge, because a hole may be made into which the dynamite cartridge will not enter freely.

COGS are cribs of timber filled with waste rock. They may be erected quickly, have great strength, and are especially useful in preventing an impending squeeze underground.

DREDGING FOR TIN is a success in Siam and the Malay States, but inability to wash thoroughly the clay leads to considerable losses of the cassiterite. Clay also reduces the digging capacity.

ORE CLASSIFICATION by the Chino Copper Co. has the following designations: 0.00 to 0.79%, poor; 0.80 to 0.89%, low No. 1; 0.90 to 0.99%, low No. 2; 1 to 1.24%, fair; 1.25 to 1.49%, good; 1.50 to 1.99%, excellent; and 2% upward, superlative.

A SQUEEZE is defined in Pennsylvania as being caused by the general subsidence of the strata overlying a coal-bed or ore deposit, due to part failure of the pillars. When this subsidence radiates from origin it is called a creep. Another meaning of creep is movement of the floor, due to pressure of pillars.

PYRRHOTITE is the mono-sulphide of iron. It is usually slightly magnetic and occasionally contains nickel. In Californian mines in granite it is often the principal sulphide in the ore. Pyrrhotite also is abundant in most of the copper mines of the Pacific Coast where large bodies of massive sulphide are mined.

CONCRETE RETORTS are now being used in the manufacture of the pine-oils made by destructive distillation. The use of such retorts permits the production of an oil containing only a minimum proportion of pitch, which is drawn from the bottom of the apparatus. Such oil, low in pitch, is a good frother and does not lift the gangue.

THE STRIKE of a vein or formation is always at right-angles to the dip. If the dip is known and stated, it seems unnecessary to give the strike also, which is often awkwardly expressed, as "the strike is north-west and

south-east, with a dip to the north-west." If the dip is described as north-west then it is known at once that the strike, being at right angles to this, must be north-east.

SAMPLES of copper ore at Santa Rita, New Mexico, are of four kinds, taken concurrently, namely: prospect-hole samples, pit samples, car and steam-shovel samples, and blast-hole samples. An average of 2400 assays and determinations is made each month, costing from 42 to 86c. per assay.

GOLD from the gravel of Manhattan gulch, Nevada, had the following fineness during the past 6 years: 703, 709, 706, 716, 721, and 731. This regular increase toward the mouth of the gulch is thought to be due to the solution, through long action of the surface water, of part of the silver and nearly all of the base metal contained in the gold.

ALUMINUM possesses to a high degree the ability to remove traces of oxygen from steel, small quantities, 0.05%, 'killing' the steel. In itself, it is a more efficient de-oxidizer than manganese or silicon, but when considered as the sole means of de-oxidizing the steel rather than as an ingredient to be used for removing the last traces of gases, there are objections to its use.

MANGANESE added to steel acts as a carburizer or a de-oxidizer. These functions may be classified as follows: In foundry practice: (1) Its use as a de-oxidizer and desulphurizer; and (2) its use to alter the constitution of grain in the metal. In steel-works practice: (1) Its use as a de-oxidizer; and (2) its use to impart certain static properties to steel.

IN MINING under lakes, reservoirs, rivers, or the sea, the following conditions must be considered: (1) The character of the overlying strata, with special reference to loose deposits of alluvium or beds of clay between the bottom of the water and ore deposit; (2) the presence of faults and dikes in the strata; (3) the dimensions of pillars to be left and the width of openings to be made; and (4) the necessity of leaving ore next to the roof in some cases.

WEIGHT of rocks is frequently discussed, so the following table should be worth study:

Rock	Average specific gravity	Weight, pounds per cubic foot	Cubic feet in short ton
Andesite	2.9	181.0	11.1
Basalt	2.9	181.0	11.1
Diabase	3.0	187.0	10.6
Diorite	3.0	187.0	10.6
Granite	2.7	168.0	11.9
Limestone	2.7	168.0	11.9
Porphyry	2.7	170.0	11.8
Quartz	2.6	162.1	12.3
Rhyolite	2.4	149.6	13.4
Sandstone	2.4	149.6	13.4
Schist	2.7	168.0	11.9
Shale	2.6	162.1	12.3

Diamonds in California

By W. H. Storms

The occasionally reported discovery of diamonds, in the gold-bearing gravel mines of California, recalls to mind the fact that diamonds have frequently been found at a number of localities in the State, though, thus far, none have been found anywhere but in the gravels of streams, either ancient or recent; that is, no diamonds have been found in the solid rock in California. In nearly all of the districts of California where diamonds have been discovered, serpentine, or gabbro, or some other kind of rock rich in olivine, or an alteration product of it, occurs in the vicinity where the diamonds have been found, or at some place higher up on the same stream.

Diamonds were reported in California as early as 1850, and although the total number that has been discovered is large, probably several hundred, it is not unlikely that as great a number, or even more, has been lost through the failure of the placer miners to recognize the stones when cleaning-up their rockers or sluices. The concentrated material taken from the boxes contains a great number of pebbles of various colors, having usually a greater or less degree of transparency, and to the miners these little pebbles are of small value, and are thrown away. It is the gold they are seeking, and the discovery and recognition of a diamond is more likely to be the result of accident than anything else. In Butte county, in the vicinity of Oroville, the placer miners have long since realized that it is possible to find diamonds in cleaning-up and consequently they are on the lookout for them, but in other diggings the men are usually less alert, and diamonds are more than likely to be overlooked, and thrown out with the common pebbles that are so abundant in the placer mines. These pebbles are most commonly garnet, peridot (olivine), zircon, magnetite, chromic iron, quartz crystals, and numerous others, all of which collect in the sluices, or rockers, and are eventually transferred to the miner's pan when cleaning-up, so he, at least, has a good chance to detect the presence of diamonds should any be present.

H. W. Turner gives the following localities in which diamonds have been found in California: (American Geologist, Vol. 23, 1899). In Eldorado county, at Placerville, on the south side of Webber hill, in White Rock canyon, at Dirty Flat, and at Smith's Flat; in Amador county, at Rancheria, three miles south of Volcano, and at Loafer Hill, near Oleta; in Nevada county, at French Corral; in Butte county, at Cherokee Flat and at Yankee Hill; in Plumas county, at Gopher Hill, and on upper Spanish creek. It is reported that diamonds have been found also in Del Norte, Trinity, and Tulare counties, in this State.

One of the first diamonds found at Dirty Flat, near Placerville, measured, according to W. A. Goodyear,

(Fourth Report State Mineralogist), nine thirty-seconds of an inch in maximum diameter, and weighed $1\frac{1}{4}$ carat. Several diamonds were found on the south side of Webber Hill.

Mr. Goodyear says he found itacolumite, a variety of micaceous sandstone, remarkable for its flexibility, three miles east of Placerville, in a locality where diamonds had been discovered. In Calaveras county I found itacolumite in the wash of the Happy Valley hydraulic mine, a mile east of the village of Mokelumne Hill, but I found no diamonds there, nor did I hear of any ever having been found in that channel. Itacolumite is of common occurrence in the diamond regions of Brazil, and some have thought that wherever this flexible sandstone occurs, there diamonds also should be found. This belief is, perhaps, natural and yet no diamonds have ever been reported as having been found imbedded in the itacolumite, at least not so far as I have ever heard. It seems that the flexible sandstone is merely associated with diamonds in several localities, but is not what may be termed the matrix of the precious stones.

As early as 1854 Melville Atwood, an English mining engineer, wrote an article on placer mining in California that was published in a San Francisco newspaper, in which he said: "I desire to call attention to the chance of finding diamonds in this country, and the likelihood of their being overlooked. The rocks in which they occur are common in California. Itacolumite, a soft micaceous sandstone, always the associate of diamonds, is also found here. The gravel always found in the river washings so closely resembles the 'cascalho' or diamond gravel of Brazil, that I think it very probable that if the proper search be made diamonds will be found."

It should be noted that diamonds had been found in California prior to this intimation of Mr. Atwood, that they might be discovered in California, though he might not have been acquainted with that fact.

As far as I have learned, all the diamonds that have ever been discovered embedded in their natural matrix, have been found in dark, basic rocks of the peridotite group. The diamond-bearing ground of the South African mines is what is known as kimberlite, a compound of olivine and augite, usually more or less serpentinized and otherwise altered. In Butte county, California, where numerous diamonds have been discovered, is a dark green much altered rock, which seems to have been originally diabase, or some similar rock, and, although at a casual glance it might be mistaken for kimberlite, this similarity, on close inspection, is seen to be no more than a resemblance to the kimberlite of Kimberley and other South African diamond localities.

Concerning this so-called kimberlite near Oroville, D.

B. Sterrett said, in 'Mineral Resources of the United States,' 1906: "The specimens sent to the Survey as typical 'blue-earth' of the Oroville locality, do not bear much resemblance to the genuine kimberlite of South Africa. Points of likeness are the extensive serpentinization in each, a general bluish-green color, and the probable brecciation of the California rock compared with the evident extreme brecciation of the kimberlite. On the other hand, the general appearance of the two rocks on close inspection is very unlike. The California serpentine apparently does not contain inclusions of other types of rocks forming the walls, while the kimberlite contains these in quantity, as black shale, conglomerate, quartzite, melaphyre, etc. The numerous plates of biotite, common in the true kimberlite were not observed in the California rock. The presence of feldspathic material in the California serpentine indicates a quite different type of rock from the kimberlite. The latter is regarded as a serpentinized volcanic peridotite breccia, with the serpentine probably derived from a less basic rock, possibly of the gabbro or diorite class. As far as can be learned, the presence of 'bulls-eyes' (spherical balls with concentric layer structure, and concretions or nodules of calcium carbonate), is not a prominent feature of the South African diamond mines, while the occurrence of lime concretions is not limited to the outcrop of diamond pipes alone, but is common to large areas of country around Kimberley, where rocks other than kimberlite outcrop. It seems probable that the outcrop of rock near Oroville, designated as 'kimberlite' by the owner of one of the mines where diamonds have been found, is a portion of one of the belts of serpentinized amphibolite schist running through the country, in a north-west direction. * * * The alluvium has been washed off (by hydraulicking), exposing a portion of such a belt, which has been mistaken for a pipe formation, since it is exposed over a limited area. The rock formation, including the region a mile north of Oroville, represents a highly metamorphosed series of basic rocks which have yielded amphibolite schist and serpentine. In this formation are included diabase-porphyrite which would readily furnish such specimens as the 'bulls-eyes' above described. Many authenticated finds of diamonds are on record in Butte county. Some of them have been along Feather river not very far from Oroville. The majority of them have come from Cherokee Flat, north of Oroville, where a company has been formed to prospect for diamonds. Since the presence of diamonds is well established for this part of California, it remains for some one to locate them in the matrix. Just what the nature of that matrix will be is not known. It may not be a typical kimberlite rock and in the form of a volcanic rock, but one of the other varieties of basic igneous rocks so plentiful in this region. It has not been proved that a kimberlite formation is essential to the occurrence of diamonds, nor that where such rock exists it must carry diamonds. Several rock outcrops are known, as in Elliott county, Kentucky, and Kakanui, New Zealand, where there are basic rocks almost identical in appearance to

kimberlite around which no diamonds have as yet been found. On the other hand, diamonds occur in a matrix of hornblende-diabase near Inverell, Australia. Since the composition of many of the rocks of the Oroville region is not very unlike this, it may be that the diamonds will some day be found in a matrix of similar type in that region."

Henry G. Hanks, the first State mineralogist of California, in his fourth report, says that diamonds were found at Cherokee Flat, in Butte county, in 1853, and that the largest weighed two and a quarter carats. The diamonds discovered in the Cherokee diggings were rose colored and yellow, or colorless, and all were associated with zircon, platinum, iridium, magnetite, gold and olivine. Microscopic diamonds have been found in a score of places in northern California and in Oregon, but these are, of course, of mineralogical interest only, still a careful search might discover larger stones of value.

Nearly all of the diamonds thus far found in California have curved faces, some of them being almost round, with only a rough approximation to the octahedral form, or some modification of it. The rough diamond has a most peculiar lustre, and one difficult to describe. In the text books this lustre is called 'adamantine' but to get an idea of what adamantine lustre really is like, it is necessary to see a rough diamond. I have had the good fortune to see a number of rough diamonds, both colorless and those having faint shades of color, though principally yellowish. The most of them looked like colorless bits of glass, and would fail to impress the average finder as a stone having value. Some of them, though not all, possessed the adamantine lustre, others showed but little of it. Some of them looked to me like crystals that had been treated to a very thin coat of ordinary stove-polish, and I can think of nothing that will give a better idea of what adamantine lustre is like than this thin film of stove-polish, without actually seeing it in the diamond itself.

There was at one time on exhibition at the State Mining Bureau, in San Francisco, a beautiful diamond owned by the late Jacob Z. Davis. It was found at Volcano, Amador county, and was an almost perfect octahedron, colorless and with only one or two small flaws. This stone was probably the finest diamond thus far found in California, and was valued at \$500, not that it was a large diamond, for it was not, but because of its unusual beauty and the rarity of crystallization. This diamond weighed 1.57 carat. It is thus described by Geo. F. Kunz, gem expert, in Bulletin 37 of the California State Mining Bureau, page 40:

"It is a modified octahedron, about $\frac{3}{16}$ inch diameter, transparent and nearly colorless, though slightly flawed. The curvature of the faces gives the crystal a sub-spherical form, but the edges of the pyramids are channels instead of planes. Closer examination shows that the channeled edges, the convex faces, and the solid angles are caused by an apparently secondary building up of the faces of a perfect octahedron; and for the same reason the girdle is not a perfect square, but has a somewhat

circular form. These observations were well shown by enlarged drawings. The faces seem to be composed of thin plates overlying each other, each slightly smaller than the last. These plates are triangular, but the lines forming the triangles are curved, and the edges of the plates are beveled. Under the microscope it could be seen that each triangular plate was composed of three smaller triangles and that all the lines were slightly curved. The building up of plate upon plate caused the channeled edges and the somewhat globular form of this exquisite crystal. A close inspection revealed tetrahedral impressions, as if the corners of minute cubes had been imprinted on the surface of the crystal while in a plastic state. These are the result of the law of crystallization, as shown by the faint lines forming a lace-work of tiny triangles on the faces when the stone was placed in proper light."

Diamonds possess some remarkable physical properties which serve to distinguish them from all other minerals. The most prominent feature is extreme hardness, it being the hardest known substance. It can be easily broken however, as it is extremely brittle. Owing to its cleavage, lapidaries are enabled to split off slices or fragments with comparative ease, by simply placing a knife blade at the right spot and striking it a light blow with a small hammer. When diamonds are to be split in this manner they are first partly embedded in cement so that they may be firmly held while undergoing this delicate operation. When a diamond is exposed for some minutes to the direct rays of the sun and then taken into a dark place it emits a phosphorescent light that continues for several minutes, gradually becoming more dim until the light disappears. When rubbed the diamond becomes positively electric. It is not in the least affected by acids or alkalies, and although under proper conditions it will burn, it can withstand a very high temperature without being visibly affected. The heat of an ordinary blow-pipe flame has not the slightest effect on it, but in a muffle it is stated that the diamond burns at about the temperature of the melting-point of silver, though it can be highly heated in a closed crucible without any effect upon it whatever. Diamonds have a wide range of color, being colorless, red, rose, green, blue, yellow, brown, and black. It is found in many shades of these several colors, of which the most valuable stones are those having decided colors, the faintly tinted ones being much less esteemed than those that are free from color. Some years ago several sharp fellows secured a number of pale yellow diamonds that were otherwise perfect. These diamonds they dipped in a solution of purple aniline dye, the effect of which was to give the stones a most beautiful delicate bluish tint, which at that time was considered the acme of perfection in the diamond. They succeeded in disposing of the treated stones at fancy prices and the trick escaped detection for some time—until one of the purchasers chanced to wash his hands with soap and water while wearing the 'doctored' ring, when the aniline dye was at once removed exposing the deception.

The diamond feels cold to the touch, and when breath-

ed upon becomes covered with a thin film of moisture in the same way that a cold window pane is dulled when breathed upon. It is said that when the lustre of the diamond is thus momentarily dimmed, if there are any flaws in it they can be detected easily in this manner, as they then become more apparent.

Perhaps the most curious property of the diamond is that which was accidentally discovered by a man named Kersten while engaged at the sorting-table of one of the South African diamond concentrators. He had before him a miscellaneous lot of stones—diamonds, zircons, peridots, garnets, and various others, such as are constantly recovered from the concentrators. Requiring more room on the table for some purpose, he brushed the stones aside, when a number of them rolled up onto a board on which there was a quantity of tallow. As the board chanced to be lying in an inclined position all of the stones rolled back upon the table except the diamonds which remained adhering to the tallow. Kersten, being an observing fellow, noticed this strange fact, but thought it might be due to chance. He repeated the operation to see if it would by chance happen again, and then made the remarkable discovery that it did. Time and again he tried the experiment, and always with the same result—the diamonds adhered to the tallow while all stones other than diamonds rolled down the board onto the table. Realizing that he had made a valuable discovery, he applied for and obtained a patent for the idea, which he sold to the DeBeers company for a substantial price. This device at once did away with the necessity of hand-sorting the diamonds from the other stones with which they are always associated in the concentrate from the South African mines.

In consideration of this remarkable property of the diamond to adhere to a surface of tallow, it has been suggested by Geo. F. Kuntz that it might be a good idea to equip the mines in the diamond districts of California with these tallowed boards, where, if diamonds be present in the concentrate they would all be recovered if the concentrated sand be passed over one of these boards. I do not know of this experiment having been tried at any California placer mine or on any dredge, but the suggestion seems to be one worth trying, as it costs nothing and might result in the recovery of numerous small diamonds, to say nothing of larger ones. I think it would be an excellent idea to make the experiment.

Besides those in California, diamonds have been found in the United States in North Carolina, Virginia, Alabama, Wisconsin, Michigan, Indiana, Arkansas, and Ohio. The only real diamond mines in the United States, however, are in Arkansas, where there are several peridotite areas in which diamonds have been discovered, and a number of companies have been formed to explore for the precious stones. A great many diamonds have been found in these various mines and among them some fine ones, of rare shades and great brilliance. These mines are in the vicinity of Murfreesboro, but the industry has not as yet made great strides in a commercial way, though its future is by no means without promise.

Molybdenum Ores and Their Concentration

By F. W. Horton

*Although there are large deposits of low-grade molybdenum ore in the United States, and a latent market for the metal, until recently there has been little development of these deposits. A deterrent against their exploitation was the lack of any considerable demand for molybdenum. Makers of alloy-steels feared that they would not be able to get a steady supply of the metal; while, on the other hand, owners of molybdenite deposits thought that any large production of the mineral would glut the market. These two main factors depressed a market that had to be developed. Mining was by small-scale operations on high-grade ore. The U. S. Bureau of Mines therefore investigated the character and extent of the deposits of molybdenum, and how the ores might best be concentrated into a marketable product. The War has stimulated the demand for molybdenum throughout the world, but the high prices now being paid cannot last, although under normal conditions the metal should be able to compete with tungsten.

The molybdenum minerals are as follows:

Mineral and composition	Molybdenum, %
Molybdenite, MoS_2	59.95
Wulfenite, PbMoO_4	26.15
Molybdite, $\text{Fe}_2\text{O}_3 \cdot 3\text{MoO}_3 \cdot 7\frac{1}{2}\text{H}_2\text{O}$	39.63
Ilsemanite, $\text{MoO}_2 \cdot 4\text{MoO}_3 (?)$	68.18
Belonesite, MgMoO_4	52.08
Powellite, CaMoO_4	49.98
Pateraite, CoMoO_4	43.84
Achrematite, $3(\text{Pb}_2\text{As}_2\text{O}_8\text{PbCl}_2)_4 = (\text{Pb}_2\text{MoO}_5)$	3.40
Eosite, Vanado-molybdenite of lead

Only molybdenite and wulfenite are of commercial importance, the others being rare, save molybdite. Molybdenite is a soft, opaque, lead-gray mineral with a metallic lustre and greasy feel, commonly occurring in flakes or scales. Finely granular and massive forms are also common. The mineral is soft, and marks paper. Its hardness is 1 to 1.5, and specific gravity 4.7. Molybdenite is often confused with graphite, which has similar characteristics, but has a specific gravity of 2.09 to 2.23. A heat test of molybdenite gives off sulphur, graphite will not.

Probably 75% of the reported occurrences of molybdenite are in acid-igneous rocks such as granites, pegmatites, trachytes, and syenites; next in order are the metamorphic rocks such as serpentines, gneisses, amphibolite, chlorite, talc, and mica-schists; then sedimentary rocks such as conglomerates and limestones; finally in basic-igneous rocks.

Wulfenite is a molybdate of lead, containing 26.15% molybdenum and 56.42% lead. It is heavy (specific

gravity 6.7 to 7), brittle, has hardness of 2.75 to 3, and is generally orange-yellow color. It frequently occurs in well-crystallized forms, but is also found in coarse-grained or fine-grained masses. When heated with soda on charcoal it yields metallic lead. Deposits are almost wholly confined to veins, associated with other lead minerals.

The American occurrences of molybdenum minerals may be briefly described as follows:

In Arizona there are many deposits of molybdenite

SECTION OF TYPICAL MOLYBDENITE ORE FROM THE LEADER MINE, HELVETIA, ARIZONA. NATURAL SIZE.

and wulfenite, and save Nevada is the only State in which is any large quantity of the latter mineral. In fact, this ore supplied most of the molybdenum of the United States in 1915. Wulfenite deposits of Arizona are mostly in Cochise, Pima, Pinal, and Yuma counties, in the south. Molybdenite is found in Greenlee, Mohave, Pima, Pinal, and Santa Cruz counties, but is associated with copper minerals, making separation somewhat troublesome. The Mammoth, Collins, Old Yuma, and other mines are described. The first was operated for gold ore, and the tailing is being treated for its wulfenite-content.

Molybdenite is widely distributed in California, 41 occurrences in 16 counties. Forty miles east of San Diego is the property of the Santa Maria Molybdenum M. & M. Co. The molybdenite deposit consists of a large granite dike from 35 to 100 ft. wide. The mineral occurs sparingly throughout the granite in crystal aggregates and irregularly-shaped masses of radial structure. Other deposits near Bishop, Kearney Park, Corona, and Caliente are briefly described.

In Colorado molybdenite is widely distributed in al-

*Abstract from Bulletin 111 (132 pages), U. S. Bureau of Mines.

most every mountain county. Near Empire in Clear Creek county, the Primos Chemical Co. is mining three veins of low-grade ore. This occurs as an alaskite (?) breccia, in which the molybdenite appears as occasional small flakes, but oftener in finely-granular form associated with iron pyrite in the interstices of the breccia; also in small veinlets running off into the alaskite—porphyry (?) country. Production to date is between 1500 and 2000 tons of 2% ore. Eleven miles south-west of Breckenridge is an interesting deposit of molybdenite in two pegmatite veins.

In Montana there are over a dozen occurrences of molybdenum ore. At the Great Western M. & M. Co.'s mine in Park county, 10 miles from Emigrant, the nearest point on the Yellowstone Park railway branch, a mill, employing flotation, was to be built during the writer's visit. At other Montana mines the amount of development done is small.

In New Mexico molybdenite is found with copper minerals in San Miguel, Rio Arriba, and Grant counties; also with lead and silver ore at Organ, Dona Ana county. Wulfenite is found almost entirely in Dona Ana, Sierra, and Grant counties, rather commonly with silver ore in Dona Ana.

In Washington there are some interesting deposits in Chelan and Okanogan counties. At the Crown Point mine the mineral is in white vitreous quartz in fine specks to large pieces.

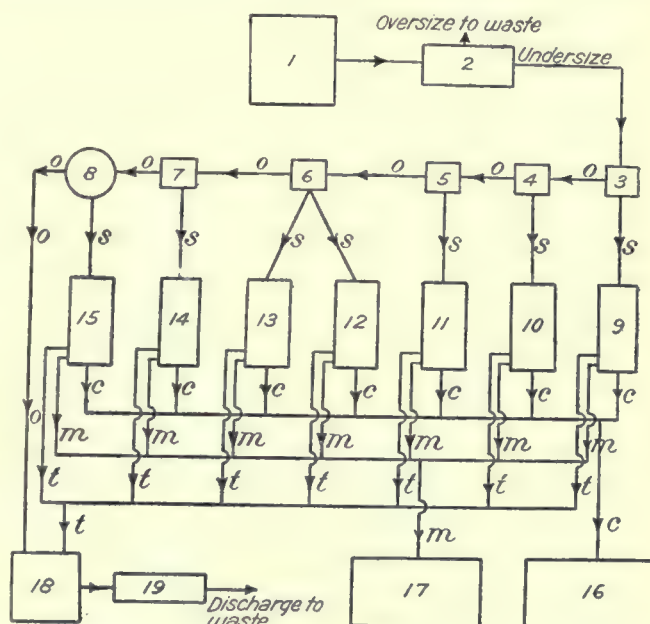

One of the best and most-easily applied qualitative tests for molybdenum is made by treating the finely-powdered ore with 5 cc. of concentrated nitric acid, evaporating to dryness, treating the residue with $\frac{1}{2}$ cc. of concentrated sulphuric acid, and again evaporating to dryness. If molybdenum is present a beautiful ultramarine blue color develops in the residue on standing from 2 to 12 hours. Other tests are given, including the Bureau of Mines quantitative method.

Outside of a small and irregular production of wulfenite concentrates the molybdenum markets of the world have been supplied largely by a product containing 50 to 90% MoS_2 , obtained by primitive methods. Successful concentration of the ores containing from 1 to 3% MoS_2 is the main factor on which the future of molybdenum mining depends. Mechanical concentration so far is economically superior to other treatment methods. Wulfenite is amenable to jig and table treatment; molybdenite is not, owing to its flaky character. Many plants erected to concentrate MoS_2 have been failures, the processes not being suited to the ores. Methods that have been successfully used may be grouped as (1) rolling and screening, (2) electrostatic, and (3) flotation. A brief discussion of these follows:

1. When the MoS_2 occurs as large flakes or crystal aggregates it may be recovered by crushing the ore in rolls, followed by screening the fine material. The success of this method depends on flattening the MoS_2 masses into flakes the largest diameters of which are greater than those of the particles of gangue. The work may be done in series. This treatment is not efficient,

and may be classed as a preliminary to other processes. Ores containing mica are unsuited to rolling and screening.

2. Molybdenite is a good conductor of electricity, and may be separated from most gangue minerals found with it by electrostatic methods. For this treatment the favorable class of ore is that in which the MoS_2 is flaky and of good size, and where the gangue is clean quartz, granite, etc. The ore must be perfectly dry and warm. Material as fine as 200-mesh and as coarse as 6-mesh may

FLOW-SHEET OF BOYKIN & HEREFORD WULFENITE MILL AT MAMMOTH, ARIZONA.

(1) 40-ton ore-bin; (2) inclined 4-mesh screen; (3 to 7) hindered-settling classifiers; (8) settling-cone; (9 to 11) Overstrom tables; (12) Ludwig table; (13 to 15) Card tables; (16) concentrate storage; (17) middling storage; (18) tailing-pump; (19) Byron Jackson 3-in. 'dreadnaught' sand-pump; c = concentrate; m = middling; t = tailing or residue.

be treated, but the coarse product gives best results. Tests made by the Santa Maria Molybdenum M. & M. Co. of San Diego, California, on an iron-stained granite containing 0.5% MoS_2 , gave 83.68% recovery by electrostatic separation. The concentrate assayed 72.42%, middling 26.9%, and tailing 0.2% MoS_2 . At present there are no plants treating MoS_2 ore commercially by such methods. Costs should not be any greater than in treating zinc ore by similar processes, say \$2.50 to \$3.50 per ton.

3. Molybdenite, like most metallic sulphides, is not wetted readily by water, floats on water when dry, and is easily wetted by most oils. Water flotation of MoS_2 ore is simple, and does not necessarily involve the use of oil, acid, or gas. The ore is fed as thin as sheet and at as uniform a rate as possible onto a moving water surface in a tank. The Wood (Denver) machine is the best known of this type. Twenty to forty-mesh ore is a good size for this process. Generally speaking, oil flotation probably offers the best method of treating MoS_2 ores, in which the mineral is flaky. Oil-flotation processes are

applicable to a wider range of sizes than are electrostatic or water-flotation methods. In Norway the Elmore vacuum-flotation system is treating successfully MoS_2 ore. Both electrostatic and flotation methods make a product that contains pyrite and other sulphides, which are objectionable, and must be separated from the MoS_2 to yield a marketable product.

Treatment of wulfenite ore presents few problems, the usual concentrating machines recovering a high percentage of the mineral. The finest particles of the PbMoO_4 are readily wetted, hence sliming does not result in the large losses made in treating various metallic sulphides under similar conditions. Wulfenite can be treated successfully by pneumatic methods also. At the Mammoth mine, 3 miles from Schultz, Pinal county, Arizona, Boykin & Hereford are treating over 200,000 tons of tailing from an old cyanide plant, which contain from 1 to 2% wulfenite. The scheme of operations is clearly shown in the accompanying diagram. The cost of scraping the tailing and delivering it into the plant is 14c. per ton. From 200 tons of tailing treated daily 2 tons of concentrate is recovered. This contains 22.62% MoO_3 , and 61.83% PbO .

The Miner's Creed

Following is a Butte miner's creed. It is good enough for miners elsewhere.

Bar down all loose ground before starting to do any other work;

Never leave candles burning on timber;

See that the grizzlies over chutes are in good repair;

Be careful around electric wiring and all electric apparatus;

Never drill alongside a missed hole;

Cut out all fooling while at work, and also rushing for cage at quitting time;

Keep the stope-floors in good repair and tidy;

Never carry powder with a capped fuse;

Give warning in ALL directions when blasting;

Bend down nails in all boards or lagging that may be lying around where men may step on them;

Keep the guard rails in place on all manways;

Never use a drill or metal bar in tamping;

Get all wounds properly treated so as not to risk infection;

Warn and help new men to protect themselves from injury by accident.

COAL-MINE FATALITIES in the United States during 1916 decreased 3% from the 1915 total. Coal production increased 12%, the output being 597,000,000 tons. The fatality rate was 3.09 per 1000 men employed. The general results show that the efforts exerted by the various agencies whose object is to reduce mine accidents are meeting with success. Among the means employed to reduce accidents may be mentioned the general use of safety-lamps in doubtful mines, the introduction of permissible explosives, humidifying dusty mines, first-aid

and rescue-training which save lives that might otherwise be lost by reason of injuries received, the enactment of industrial accident compensation laws, and the spirit of co-operation on the part of all concerned.

Introducing Coal Into Blast-Furnace Through Tuyeres

*It is the practice in Japan to introduce soft bituminous coal continuously into the blast-furnace through tuyeres. The coal-charging device is a cylinder of 3-in. inner diameter and 13 in. long, provided with a piston worked by a rod having a handle at the outer end. The coal is in lumps of $\frac{1}{2}$ to $1\frac{1}{2}$ inches. After it is filled with coal, the implement is thrust rapidly into the tuyere and the contents discharged by pushing the handle operating the piston. The contents of three or four cylinders are inserted into one tuyere at a time, and take about 10 to 15 minutes to burn out. It is necessary to use a poking-rod through the tuyere-hole to clear the tuyere and get all the coal into the furnace.

We have recently used the tuyere-coal with splendid results in a blast-furnace 11 ft. by 39 $\frac{1}{2}$ in. and 8 ft. high from the tuyere-centres to charging-floor. The height of the jacket is 4 ft. The blast-pressure is 1 lb. When 7.5% coke is used in the usual way, the furnace smelts 121 tons total charge per day, or 3.3 tons per sq. ft. of tuyere-level area. On the other hand, when 1.2 tons of coal per day is introduced through the tuyeres, the total charge is increased to 154 tons (4.3 tons per sq. ft.), the coke is decreased to 5.9%, and the limestone is reduced by 3%. Generally two workmen are added per shift when the tuyere-coal is used. The direct cost is reduced by 17%. Even if two workers are added per shift, the cost still remains 15% smaller. The splendid results obtained by using pulverized coal in reverberatory furnaces immediately suggested to us the use of pulverized coal instead of lumps for this special purpose, and experiments are now in progress with good results.

New Geological Map of California

A new geological map of California has been issued by the State Mining Bureau. The map has been compiled from data obtained from numerous official maps and sources of information, and in part by personal investigation by qualified geologists. It is a vast improvement over any previous general geological map of the State, and is as detailed as it is practicable to make a map on so small a scale—12 miles to the inch. It will be of value to all engaged in geological study of California. Besides the geology, there is delineated on the map what is known as culture, that is, railroads, highways, pipe-lines, power-transmission lines, and canals.

*Communicated by Furukawa & Co., Ashio, Japan.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

RICH ORE FOUND IN IOWA GULCH DISTRICT.

Another rich discovery, the largest in the district for 10 years, has just been made by the Ontario, Tiger, and Green Mountain Leasing Co. at the Ontario tunnel, near the head of Iowa gulch. A 4½-ft. vein, assaying from \$20 to \$40 per ton, has been cut in the adit at a distance of 703 ft. from the portal. Development that has been accomplished so far has exposed the ore for 14 ft. on a face 7 ft. high. The ore continues both above and below the adit-level. At a point where the ore was found, the adit is 580 ft. below the surface, and the breast is at least 1300 ft. from the nearest workings. The metal-contents are lead, gold, silver, and copper. The presence of a rich vein in the Tiger and Green Mountain claims has been known by a number of the present lessees for several years. In 1878 the vein was discovered near the surface on the sites of the Tiger and Green Mountain shafts, and it is stated that \$80,000 was extracted in a short time. Water caused the property to be abandoned, as it was impossible to drain with the facilities then available. Hoisting was done by means of a whim. In 1903, the property was re-opened by E. A. Smith, organizer of the present leasing company. He installed pumping-machinery, but the flow was too strong to handle. An adit-level was started later, and the Ontario was driven from the bottom of the gulch a total distance of 300 ft., where, for some unknown reason, work was stopped. The Ontario was re-opened late last year when E. A. Smith and Hector McDonald, well-known Leadville men, secured a lease on 60 acres of territory including the Ontario, Tiger, and Green Mountain properties. A contract was let for extending the adit 800 ft., a distance that was calculated to bring the breast under the Green Mountain shaft. Half of this distance was completed when the ore was encountered. It is thought that the rich ore will continue in the vein to the shaft, which is 400 ft. ahead, and is expected to extend to the Sunday line bounding the property on the north. The trend of the vein is north-east in a direct line toward Breece hill and the Ibex mine. It is reported that the vein may be the southern extension of one of the large ore-shoots opened in the Ibex. There is a noticeable stir among local mining men since the announcement of the discovery. The County Treasurer is receiving many enquiries by men examining tax-records on all available ground in the Iowa Gulch district. Prospecting is expected to be undertaken on numerous properties as soon as the snow has melted. Iowa gulch, while it was one of the rich parts of early-day operations, has been developed on a meager scale, and it might be stated correctly that the area is practically new. Undoubtedly other rich veins exist in the ground. Shareholders of the Ontario, Tiger, and Green Mountain Leasing Co. are all local mining and business men. They are: Alfred Hoffman, Arthur Lumsden, J. H. Fiske, T. D. Kyle, Ike L. Jones, E. A. Smith, Hector McDonald, Otto Thurn, Paddy Connors, W. G. Collins, Arthur Dalrymple, J. B. Jackett, and N. Nyboe.

The Greenback shaft has been unwatered to the bottom, or 1350-ft. depth. The present flow of water is 500 gal. per minute.—Fanny Rawlins on Breece hill is yielding over 2 oz. gold ore, also some copper.—In spite of the snow the Kokomo-Robinson district gains in activity. At the Golden Queen in this district 8 ft. of lead-zinc-silver ore has been opened.

ENGELS, CALIFORNIA

COPPER MINING IN PLUMAS COUNTY.

During the past two years Plumas has become one of the leading copper-producing counties of California, Shasta leading with over 40,000,000 lb., Calaveras with over 4,000,000 lb., and Plumas with over 4,000,000 lb. Lack of adequate transportation has been the principal cause against rapid development of the region, but through the efforts of the Engels Copper Co. the Indian Valley railroad has been completed from Keddie, on the Western Pacific, to Crescent Mills, and will reach the Engels mine in the early spring. It is reported that a branch will be extended to Genesee and that another line has been projected that will serve the Walker mine and

MAP OF PLUMAS COUNTY, CALIFORNIA. PREPARED BY STATE MINING BUREAU.

other properties in the vicinity of Portola, a thriving town on the Western Pacific railway.

The prominent mines on the Plumas copper belt are now in the hands of strong corporations, insuring their economical and thorough development. The Walker mine, 20 miles east of Portola, is controlled by the International Smelting Co., and most of the territory located between the Walker and Engels mines recently passed under option to the United States Smelting, Refining & Mining Co. This corporation has installed equipment on the Five Bears, Iron Dyke, Eagle Hill, and other properties, and plans thorough development with the passing of winter. The Walker interests of Salt Lake City, connected with the Walker mine, are working the Bonita, a nearby property, and have other holdings under bond. The International Smelting interests are exploring the Green Ledge, Tutt, and other groups. Several Eastern companies have representatives in the field. Most of the copper ore contains good gold and silver-content. It is ideal for treatment by flotation.

The Walker mine is among the most interesting properties

in the county. It has been developed from a prospect to a producer in approximately three years, during which time litigation hampered work, and low copper prices discouraged financing of the enterprise. Taken over from local people of limited means by J. F. Cowan and the Walker Bros. of Salt Lake City, the mine was opened by a shallow shaft, several adits and cross-cuts, and prospected with diamond-drills. Encouraged by results, a flotation plant of 100-ton capacity was erected in 1916. In the fall of last year the mine passed to control of the International interests. The group contains 34 heavily-timbered claims, and the ore is moved from the shaft to the mill by a Leschen aerial tram 4200 ft. long, with a capacity of 250 tons in 16 hours. The tram operates by gravity, the plant lying 800 ft. below the mine ore-bins. Direct flotation is employed. An Allis-Chalmers jaw-crusher and ball-mill deliver pulp to Dorr classifiers, Callow cones and cells, and an Oliver filter. At present the plant is treating 75 tons of ore daily. Concentrate is shipped to the Tooele smelter at International, Utah. It is understood that the company proposes to increase the capacity of the plant in the coming summer, and to develop the mine more vigorously. V. S. Hart is manager.

COBALT, ONTARIO

SILVER FOUND IN THE LOWER CONTACT.

The new silver vein recently discovered just below the lower contact in the Beaver Consolidated is 8 in. wide and averages 2000 oz. per ton. In addition to a large amount of high-grade ore, the wall-rock contains \$75 per ton. In all there is nearly 7 ft. of high-grade ore. After mining for the past 10 years in the Keewatin formation, which overlies the diabase to a depth of approximately 500 ft. in that part of the Cobalt silver area, and after paying on an average of \$6000 monthly dividends for these ten years, the Beaver was generally thought to be nearing the end of its reserves. However, after a preliminary diamond-drilling, which determined the underlying diabase sill to be 1000 ft. thick, the management decided to sink through this sill and explore the underlying Keewatin. Accordingly in July last the main shaft was continued to the 1600-ft. level, where, after cutting a large station about a month ago, lateral work commenced, with the result that work is now being carried on at four different faces below the lower contact. When it became known that high-grade ore had been opened in the lower workings of the Beaver, greater enthusiasm prevailed in local mining circles than has been shown in several years. The proving of the existence of silver 1600 ft. below the surface is believed to mark another era in the history of mining at Cobalt. Mining men with property near the Beaver are especially pleased, and there is much talk of renewed activity on a number of hitherto doubtful properties; in fact, deep mining will now be the slogan. The Temiskaming mine, which adjoins the Beaver, is being deepened to the lower contact, where it is proposed to connect its workings with a cross-cut from the Beaver, and thus establish good ventilation. This shaft of the Temiskaming is already down over 1500 ft., and before the end of February the workings of these two mines will be connected.

PORCUPINE, ONTARIO

PROGRESS AT THIS IMPORTANT GOLDFIELD, ALSO LARDER LAKE.

The Hollinger Consolidated is being developed to a depth of 1250 ft., and the large orebodies continue as persistent as ever. Furthermore, there is no sign of diminishing gold-content at depth. At present 1300 men are employed in extensive operations. Early in July the management expects to have the new part of the mill in operation, thereby raising the capacity from 1800 to 3800 tons daily. The many veins in the Hollinger are usually from 3 to 12 ft. wide, averaging around \$10 per ton. To extract sufficient ore for the mill from these comparatively

narrow veins is a problem. To secure sufficient labor is another problem, also the shortage of cyanide. The Hollinger is only one of the large gold mines situated in the small Porcupine goldfield.—The Dome mines will be treating 2000 tons of ore daily by the middle of summer. This, together with the five other mills with an aggregate capacity of twelve hundred tons daily, and the several other plants that are to be erected, within the next year or so, is expected to bring the production of gold from the Porcupine area up to at least \$25,000,000 annually, over one-quarter of the United States total in a year. Eight years ago there was one prospector's cabin on the shores of Porcupine lake, where today the district boasts of four thriving towns.

There is probably more activity in the Larder Lake gold area than for 10 years past. The Goldfields company has taken the lead and is now developing on the 300-ft. level. A power-plant at Little Windigo, which is owned by the Goldfields, from which the property gets current for its machinery, is being overhauled and enlarged. The Goldfields controls a large area of the choicest of the Larder Lake mineral belt, and development will be watched with interest. The rock formations of the district are remarkably similar to those over an area of at least 400 square miles. Whereas the T. & N. O. railway passes in front of the Boston Creek and Kirkland Lake fields, Larder Lake section is over 20 miles from rail, this tending to impede progress. It is thought that Larder Lake will be entered by the T. & N. O. within two or three years, if the development of some of the properties is successful. The region abounds in game and fish.

GOLDFIELD, NEVADA

A RUN AROUND THE ACTIVE MINES.

It is reported that the Goldfield Consolidated is preparing for resumption of work at the Grizzly Bear mine, idle for a year. It is rumored here that the important strike made at a depth of 1750 ft. by the Atlanta company is largely in Grizzly Bear ground. The Atlanta holds a lease on the mine below the 1500-ft. level, and has been doing some work in this area. Minor troubles continue to delay operation of the Consolidated's flotation plant, but it is expected by the management that the first 500-ton unit will go into commission in two or three weeks. The Atlanta company has arranged for the treatment of 100 tons of ore daily at the flotation plant of Goldfield Con., and has commenced shipments from the vein lately intersected on the 1750-ft. level to custom plants. The pay ore is over 5 ft. wide, and has been opened for a length of 100 ft. It is said to average \$50 per ton in gold, silver, and copper, including a 10 to 18-in. streak in the hanging wall that shows specimen ore.

The Red Hill Florence Co. has started extensive work under the management of H. D. McMahon. Repairs to the main shaft are under way and foundations are laid for a 50-hp. electric hoist, compressor, and other machinery. It is estimated 90,000 ft. of timber will be required for the shaft to the 800-ft. level. From this level cross-cuts will be driven to find the main Florence vein. The company is a merger of the Florence American, Florence Extension, and Red Hill companies, and was organized on the assessable basis.

Great Bend has entered the list of shippers, dispatching 10 tons per day of \$30 to \$40 ore. This is coming from the 210-G raise above the 300-ft. level. The drift from this level is entering similar ore, and prospects for development of a good quantity are encouraging. From the 160-ft. level a drift is advancing on low-grade ore.

The Cracker Jack company has purchased the Rabbitt Trail, General Washington No. 1, Gold Queen Extension, and Triangular Fraction claims, a total area of 50 acres. The discovery that the Cracker Jack vein dips flatly into the purchased area hastened its acquisition. A new pump has been installed on the 520-ft. level of the Cracker Jack shaft, and from this point

drifts will be extended to open the Cracker Jack and Rabbit Trail veins.

Goldfield Merger is preparing to drive in hopes of intersecting the vein exposed in the Atlanta. The manager of the Silver Pick, reports that the orebody encountered 195 ft. west of the 1050-ft. level shows a width of 16 ft., with the foot-wall

road conditions permit; the Champion is one. This mine has been worked with varying success by different companies. Some rich ore has been extracted, and it is considered a property of promise.

Spring placer mining in southern Oregon is under way. A number of the placers can only work during spring while water is plentiful, although some of the larger mines with their long ditches are more fortunate.

PROPERTY MAP OF GOLDFIELD, NEVADA.

still to be reached. It is thought that some of this ore can be extracted profitably. Development is going ahead steadily at the Grandma, Kewanas, Sandstorm-Kendall, and several other mines. The receiver, Harry B. Clapp, has placed the indebtedness of the Florence Goldfield Mining Co. at \$344,318 to date. A detailed report will probably be filed soon.

BAKER, OREGON

MINING IN NORTH-EAST AND SOUTH-WEST OREGON.

The Buck Gulch Mining Co. has been working all winter with a few men driving in gravel and developing preparatory to stoping and sluicing operations. The mine is three miles from Sumpter, Baker county. Two years ago the present company acquired the mine from Sumpter people and drove an adit 1000 ft., opening the cemented gravel of an old river-channel, which had been prospected previously from the surface. It is understood that recent sampling of the gravel has given encouraging returns, and that there is a large quantity of it. Shareholders are mainly California people. Martin Costello is manager. The mine is fully equipped.

Twohy Bros. are working their copper mine near Grants Pass. It is proving to be one of the best mines in the State, and it is expected that the owners will do a large amount of work this year.

The Conner Creek mine near Huntington, in Baker county, where a rich discovery was made in December, previously mentioned in the PRESS, is operating its 10-stamp mill on good ore. The high-grade ore has been nearly extracted, but there is a good vein of milling ore that is developing well. The rich ore exists in pockets; some large ones were taken out years ago.

The Laclede mine near Baker, in Baker county, has been re-opened under the management of John Gyllenberg of Baker. The mine was operated years ago, but has been shut-down for several years. It is understood that a large amount of money is to be spent should preliminary work warrant it.

Several mining deals of importance are pending in the Bohemia district out from Cottage Grove, waiting for the heavy snow to melt. One engineer from Spokane recently made an examination in spite of the weather. Several old mines are expected to be re-opened this spring as soon as

JACKSON, CALIFORNIA

HARDENBURG MINE.—TREASURE AND ORIGINAL AMADOR MILLS.

Unwatering and repairing the shaft at the Hardenberg mine on the Mokelumne river is finished, and actual mining operations have been started. Two levels, at 850 and 1000 ft., were opened by former owners and ore was opened at both points, a 6-ft. shoot, 430 ft. long, of good value, on the 1000-ft. level. The heavy hanging wall and black-slate gouge foot-wall made former operations expensive, but it is thought that the ore can be extracted profitably. The vertical shaft has three compartments, and has been sunk 1100 ft.; this depth will be increased to 1500 ft., at which point it should intersect the vein. The mill is equipped with 20 stamps and eight Frue vanners, and both hoist and mill are electrically driven. The mine is being re-opened by the W. J. Loring company.

The new mill at the Treasure mine, north of Amador City, is doing good work. The recovery is stated as 90%. This plant began crushing on July 5th last, and with the exception of time lost during the strike has been steadily and profitably employed on ore extracted during sinking.

The Hardinge mills, which superseded the stamps at the Original Amador mine, are said to be satisfactory. The mill was re-modeled during last fall, a ball-mill and a pebble-mill being installed. The recovery made is slightly over 90%, and the new equipment treats 100 tons per day more than was possible with the 20 stamps formerly used.

Average progress in sinking the Central Eureka shaft to 3400 ft. is 15 ft. per week. Driving is in progress on the 6-ft. vein cut by the 2500-ft. cross-cut early this month, and the gold-content continues good. Mill ore is also being extracted from the 2825-ft. stopes. Thirty stamps are crushing.

TORONTO, ONTARIO

COBALT, PORCUPINE, AND KIRKLAND LAKE.

The finding of rich silver ore on the lower contact between diabase and Keewatin formations, at a depth of 1600 ft. in the Beaver Consolidated, has aroused much interest at Cobalt. It means much for the future of that part of the field.—The new 75-ton flotation plant at the National had a few trial runs, but it closed temporarily on account of machinery troubles.—During 1916 the Crown Reserve made a profit of only \$2973 out of \$191,822 gross.

At Porcupine, labor shortage has interfered with work at the Hollinger.—The vein at 200 ft. in the Schumacher is 22 ft. wide, worth \$6 per ton.—The Newray has let a contract for 10,000 ft. of diamond-drilling.—Some high-grade ore has been opened at 300 ft. in the Davidson.

Kirkland Lake will show more activity when the power-line from Cobalt is completed.—The Teck-Hughes 100-ton mill awaits current for motors.—The Lake Shore is to erect a 100-ton mill in March.—The Kirkland Lake company has completed plans for a large plant.

Seven feet from the vein mentioned in the Beaver, and parallel with it, is another of similar formation and value. The rock occurring between the two veins is intersected with calcite stringers running horizontally from one vein to the other, carrying heavy leaf silver.

North-east of Cobalt the Dickson Creek company is sinking on a 10-in. vein in conglomerate. The shaft will be deepened to the diabase contact.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

ANCHORAGE. This division of the Federal railroad employs 1962 men. Fair progress is reported from the Matanuska and Turnagain branches.

JUNEAU. During January the Alaska Gastineau company treated 173,300 tons of \$1.24 ore, with 81.95% recovery. In December the total was 196,495 tons of \$1.22 ore.

In the appeal suit of the Alaska Juneau v. the Ebner company concerning water-rights on Gold creek, the Circuit Court of Appeals upheld the previous decision, so the Ebner gets 3200 miner's inches of water for operation in Last Chance.

ARIZONA

Bulletin 49 of the Bureau of Mines at Tucson deals briefly with ores of aluminum, platinum, tin, cadmium, nickel, cobalt, arsenic, and bismuth. Occurrences of these minerals are practically unknown in Arizona.

CHLORIDE. Utah people, headed by A. M. McDonald, have purchased the Payroll mine on lease and bond. It has been opened to 400 ft., and shows good zinc ore at depth.

OATMAN. Shipments of bullion have been made from the Tom Reed and United Eastern mines from January operations. The latter sent four bars weighing 350 lb. to the Mint at San Francisco, the first consignment from this mine. About half of the January run was on ore, the balance of the time being consumed in adjusting the new mill to its requirements. The normal capacity is 200 tons per day. Ore treated in January averaged \$21 per ton.

The United Eastern shipped February 20 gold bullion weighing 405 lb. avoirdupois, the clean-up for the first two weeks of February.

Four feet of low-grade ore, which shows colors in panning, has been cut on the 400-ft. level of the Adams mine. One piece taken out shows free gold. The cross-cut is 12 ft. into the vein without finding the foot-wall. The property is in the Black Range section of Oatman.

Sinking has been resumed at the Nellie, which was shut-down for three weeks by an accident to the hoist. The shaft is in the vein at 370 ft., and will be continued to a depth of 500 ft., where the vein will again be developed. Some good ore was encountered on the hanging wall on the 350-ft. level, but gold-content was erratic.

A station has been cut at 600 ft. in the Big Jim mine, and as soon as a sump has been cut out cross-cutting will be commenced. The vein should be encountered within 90 feet.

RAY. The Ray Consolidated Copper Co. reports as follows for the last quarter of 1916:

Development opened 19,965 ft. of ground. Ore reserves were re-calculated during the year, giving an additional 20,000,000 tons of 1.5% ore, making the total 91,000,000 tons averaging 2.05% copper. To date over 13,000,000 tons has been extracted. Mining during the period cost 84.16c. per ton, including 5.34c. for coarse crushing. The mill treated 871,700 tons of 1.649% ore, with 75.32% recovery. The last three periods of 1916 showed increased tonnages and production. The copper output, including 940,950 lb. from ore shipped direct to the smelter at Hayden, was 21,651,956 lb. The mill results are the best recorded, due to improvements. The power-plant additions are complete. Dividends totaled \$789,302. The net cost of production was 9.769c. per pound.

TUCSON. In driving an adit to open the andesite-rhyolite

contact, known to carry high gold-content, the Arizona-Tonopah Mining & Milling Co. has cut an immense body of low-grade copper ore, from 20 to 100 ft. wide, carrying chalcocite, bornite, and chalcophyrite. The company is making preparations to sink a three-compartment incline shaft to a depth of 1000 ft. Modern air-drills and semi-Diesel gas-engines are installed at the property, and work is progressing much faster than heretofore. A. J. Harshberger is superintendent. Additional property has just been bought at an approximate cost of \$85,000.

ARKANSAS

On account of cold weather and bad roads in January zinc production of northern Arkansas was low, only 1148 tons.

CALIFORNIA

AUBURN. The Valley View mine, 8 miles from Lincoln in Placer county, was sold by the W. B. Hellings estate of San Francisco to J. C. Winters and others of New York for \$100,000. Machinery worth \$75,000 has been ordered. E. P. Stephenson of the Sacramento Ore Testing & Machinery Co. sampled the mine. The ore contains gold and copper.

BISHOP. The valuable tungsten deposits near Bishop, the principal town of Owens valley, are described in a report (Bulletin 640-L, by Adolph Knopf) just issued by the U. S. Geological Survey. These deposits are mined in Deep canyon, which traverses an isolated group of hills at the base of the Sierra Nevada. Similar groups of hills farther south in Owens valley are known by distinctive names, such as the Alabama hills, and the name Tungsten hills has been suggested for the group in which the principal tungsten deposits have been found. The hills reach an altitude of 6000 ft., or about 1500 ft. above the floor of Owens valley, but they are dwarfed into insignificance by the range behind them, which towers to 13,000 ft. Tungsten ore was first found in place in August, 1913, on the Jackrabbit claim, near the present centre of mining activity. Three partners, who were mining placer gold in Deep canyon, found that the concentrate they obtained was difficult to clean because the gold was invariably accompanied by a heavy white mineral. This troublesome material proved to be scheelite, and when its identity and value became known search for it was soon begun. It is reported that after all the quartz float in the area adjoining Deep canyon had been broken open in vain during a search that covered 18 months, the scheelite was finally found in its rock matrix by J. G. Powning, who while out hunting, recognized the long-sought mineral in an outcrop of garnet rock on which he had just shot a rabbit, an incident to which the discovery claim owes its name. At this place the scheelite is embedded in the blackish garnet rock in particles, somewhat larger than those commonly found in the orebodies of the district, but it is neither so prominent nor so obviously recognizable that it would have been found had it not been the special object of search. The discovery that the scheelite occurs in the garnet rock, however, made prospecting for tungsten simple. The blackish garnet masses on the bare hills contrast notably with the prevailing gray and reddish granite and are therefore easily recognized. They were soon staked and were then tested for tungsten, and in this way ore was found at many places. As a rule this scheelite is so inconspicuous that the largest orebody, although it outcrops prominently, was at first unfavorably reported on by competent engineers, because

they were unable to ascertain its trend and consequently its width and length. The deposits, although found in 1913, remained practically unknown until the spring of 1916, when their exploitation was energetically begun. By midsummer two mills, having a total daily capacity of 400 tons, had been completed and were in active operation. The ore consists of scheelite, garnet, epidote, quartz, and other minerals. The country-rock is prevailingly granitic, but it includes isolated masses of limestone which became mineralized soon after the magma that now forms the granitic rock was intruded into them. The metallic vapors then given off from this magma altered the limestones to masses of garnet-carrying subordinate scheelite, and these altered rocks are the tungsten deposits now under exploitation. The orebodies that are now mined are from 20 to 60 ft. wide and from 150 to 260 ft. long. The ore carries from 1.5 to 2% of tungsten trioxide (WO_3). The area in which scheelite-bearing deposits have been found forms a belt 20 miles long, but the prospecting now going on

Diagrammatic sections showing the relation of the metamorphic-sedimentary rocks and orebodies to the intrusive-granitic rocks of the Tungsten hills, California. A, at the time of intrusion; B, at the present time, when erosion has removed most of the rock that formerly covered the granites and has evolved the existing topography. 1, metamorphic-sedimentary rocks; 2, limestone; 3, tungsten orebodies; 4, granitic rock.

will doubtless extend the dimensions of the field. These deposits, like those discovered in recent years in Humboldt county, Nevada, are of the contact-metamorphic class, a well-known source of copper and iron, but until lately not widely recognized as a possible source of tungsten.

REDDING. The Gardella company, operating on Clear creek, is soon to construct another dredge. Four boats are expected to be working by the end of 1917.

IDAHO

KELLOGG. During 1916 the Caledonia Mining Co. mined 17,464 tons of ore assaying 29.81 lb. lead, 74.28 oz. silver, and 2.2 lb. copper. The gross value was \$1,769,670. Costs were \$3.42 per ton. The profit was \$1,154,763. After paying \$78,150 per month in dividends, cash in banks amounts to \$309,395. included in a surplus of \$441,982.

MISSOURI

JOPLIN. Prices for ores improved last week, the average being \$88 per ton for 60% blende, \$45 for 40% calamine, and \$104 for 80% lead. The total output was worth \$660,628.

Turbine troubles at the Empire District company's steam plant have curtailed work in the district.

MONTANA

BUTTE. Ore reserves of the Bannack gold mine are estimated at 130,700 tons of ore averaging \$7.34 per ton, also 106,000 tons of \$6 ore. Estimated profits in these quantities are \$1,160,000. Current debts total \$114,144, for which bonds of \$125,000 are to be issued. The new mill will resume in the spring.

HELENA. A report has been made by C. E. Fryberger on the property of the Scratch Gravel Gold Mining Co., which is two miles north-west of Helena. The vein consists of quartz in andesite. Reserves are estimated at 49,711 tons averaging \$24.50 per ton. So far only the high-grade ore has been extracted and sent to the East Helena smelter, which returned \$50 per ton gross on 3694 tons. Probable ore on the 500 and 600-ft. levels is valued at \$1,939,311 net. The company is erecting a mill of 200-ton capacity, in which custom ore will be treated also.

(Special Correspondence.)—According to present indications mining will be active in all of the old districts near Lewistown in central Montana. The success obtained last summer in re-opening old mines in the Judith mountains has attracted capital to the Maiden and Cone Butte districts. Eastern people intend to examine carefully the Spotted Horse, Maginness, and Cumberland mines at Maiden, with a view to purchasing and consolidating them. The Sutter claims on West Armell creek are also under consideration. The metal-content at Maiden is nearly all gold, while in the Sutter group it is mostly copper.

The Mammoth claims near Giltedge has been bonded to Butte people for \$35,000. This property is equipped with a 50-ton cyanide mill, which produced considerable gold from ore worth \$6 per ton several years ago. It has been closed since on account of disagreement among the owners. Development will be started early in the spring, and \$15,000 will be spent in repairing the property and searching for new orebodies. If results are satisfactory the mill will resume.

A large body of gold ore has been found in the Big Chicago property in the Cone Butte district of the Judiths, according to R. J. Mellor, who has been prospecting there for several months. An adit has been driven 200 ft. on the shoot, which has been prospected for 3000 ft. The value is variable, but averages \$2 per ton. Work is active on several lead-silver properties in this district. Badger and Lachovich recently shipped a carload of high-grade copper and lead ore to the East Helena smelter, with satisfactory returns.

The ownership of the townsite of Maiden in the Judith mountains is in doubt. It is the oldest town of any size in central Montana, and has 150 inhabitants. W. M. Hausel has filed on a half section of land that covers the town. It is claimed that the place grew on unpatented placer locations, and that the plat of the town was never recorded. One patented mining claim of 20 acres is embraced in the homestead, and without doubt will stand. It is said that no assessment work was done on the placer claims sold for town lots and that the townsite is therefore Government land. The owners have paid taxes on their lots for many years. Fire destroyed much of Maiden several years ago, but there are about a dozen occupied business blocks and many residences on the land whose ownership is in doubt.

In the North Moccasin mountains the Barnes-King properties are producing at the rate of \$15,000 per month, employing 60 men. Lessees at the Kendall mine have ceased to mill the ore on account of weather conditions, but are extracting ore and doing development with favorable results. According to A. S. Wright, a well-known mining promoter of Lewistown, plans are being made to re-open the Gold Links mine at Kendall. Work will soon be started, and if it proves successful a 200-ton cyanide plant will be erected. The Gold Links adjoins the Barnes-King, and is opened by a 535-ft. shaft. It is said that the shaft was in ore when the mine was closed some years ago.

Lewistown, February 15.

Phosphate deposits of the Garrison and Philipsburg fields are described by J. T. Pardee in Bulletin 640-K of the U. S. Geological Survey. The economic results of the investigation may be summarized as follows:

Workable deposits of high-grade rock phosphate (containing 60% or more tri-calcium phosphate) occur in both the Gar-

rison and Philipsburg fields. That in the Garrison field lies 6 to 10 miles north of the town of Garrison and is easily accessible, and the portion considered as available to mining contains by estimate 97,000,000 long tons, an amount about twice as great as the total production of the United States to date. About one-third of the amount lies above the natural drainage-levels, and much of this can be readily extracted by means of adits driven along the phosphate bed. In the Philips-

THOMPSON. The Mason Valley company's smelter, idle for over two years, is again in blast.

VIRGINIA CITY. About 600,000 tons of \$4 tailing from the old Comstock mines is to be treated by a 150-ton plant being built for the Dayton Placer Recovery Co. G. T. Hansen is president of the company at Dayton.

NEW MEXICO

(Special Correspondence.)—The Socorro mill marketed 10,500 oz. of gold and 616,520 oz. of silver during 1916. Excluding shipments made direct to smelter, the Mogollon district produced 17,681 oz. of gold and 987,870 oz. silver in 1916. This is 50% of the silver and 26% of the gold produced in New Mexico last year. For the past 15 years or over, Mogollon has produced without fail at the rate of \$1,000,000 per year. With the prospects of cheap hydro-electric power, and that lower-grade ore can also be profitably treated, past production will undoubtedly be materially increased.

Mogollon, January 30.

SANTA RITA. During the last quarter of 1916 the Chino Copper Co.'s profit was \$3,428,976, of which \$2,174,950 was paid in dividends. The cost was 8.89c. per lb. of copper. There was treated at Hurley 790,000 tons of 1.78% ore, yielding, with crude ore smelted direct, 20,602,946 lb. The year's output was 75,551,322 lb.

OREGON

CORNUCOPIA. There is a possibility of a new electric power-line being erected to the Cornucopia mining district this year to supply current during the low water season. The Eastern Oregon Light & Power Co., with offices at Boise, Idaho, has been approached recently by R. M. Betts of the Cornucopia Mines Co. The nearest power-plant is 26 miles from Cornucopia, at Copperfield, Oregon, on the Snake river, and is known as the Ox Bow. During the past year an effort was made by the Electric company to construct a line; but nothing was done, as the company wished to stop the local power-plants, if its line was put in, and as the water is ample for power purposes during eight months of the year and considerably cheaper than the power from the company mentioned, this could not be considered. The mining companies, however, would be glad to have the line so as to operate full capacity during the winter months. The present winter has been harder than usual on the local power, due to little snow and very cold weather.

TEXAS

AUSTIN. The graphite deposits of Burnet and Llano counties have been examined by W. B. Phillips, former director of the Bureau of Economic Geology and Technology. The deposits are considered to be extensive, and of high quality. The mineral is of the crystalline variety. The ore should yield 8 to 10% flake graphite.

EL PASO. During 1916 ores and metals passing through this place from Mexico were as under:

	Tons	Value
Copper ore	5,908	\$86,266
Copper matte	683	12,021
Gold ore		36,314
Gold bullion		80,441
Lead ore	46,434	284,081
Silver ore		738,262
Silver bullion		566,730
Zinc ore	38,286	761,323

UTAH

AMERICAN FORK. Gas issuing from the limestone in the Miller Hill adit has suspended work at the face, in spite of an exhaust fan working at capacity.

BINGHAM. During the last quarter of 1916 the Utah Copper Co. made a profit of \$8,503,926 from milling operations, and a

PART OF MONTANA, SHOWING PHOSPHATE FIELDS.

burg field too little work has been done to justify a tonnage estimate, but the deposits are believed to be extensive, and are known to be in two places at least of workable size and readily available to mining.

NEVADA

AURORA. During 1916 the Aurora Consolidated yielded gold worth \$621,252. The expenditure was \$65,817 above this.

BATTLE MOUNTAIN. The Antimony & Silver Mines Co. of Salt Lake City is erecting a mill on its property near this place. The grinding equipment has been ordered from the Denver Quartz Mill & Crusher Co.

BELMONT. The Highbridge shaft of the Monitor Belmont company has been opened to the 200-ft. level. The vein which is over 15 ft. wide on the 75-ft. level shows no diminution in size. A five-drill compressor and enlarged hoist are being installed. The mill is closed pending alterations.

ELY. During the last quarter of 1916 the Nevada Consolidated Copper Co. treated 979,329 tons of ore averaging 1.63% copper. This was a decrease of 41,217 tons. Open-cuts supplied 79% of the ore, the remainder coming from the Ruth mine. The output of metal was 22,898,228 lb. Cost of production was 9.32c. per lb., an increase of 0.65c. From the net earnings of \$4,526,027, dividends were paid totaling \$2,999,186. Assets, including metals at smelter, in transit, and refinery are valued at \$9,265,013.

On account of additions to the Nevada Consolidated mill and smelter the Nevada Northern Railway, now hauling 12,000 tons daily, is preparing to carry 18,000 tons.

GOLDFIELD. At a depth of 73 ft. below the 1017-ft. level the Jumbo Extension core-drill has cut the alaskite-shale contact. There is no value in the rock so far.

total of \$10,651,608 from all sources. Dividends amounted to \$5,685,715. Overburden removed was 1,287,503 cu. yd. The mills treated 2,846,600 tons of 1.4742% ore, recovering 60.44%. This quantity was 557,700 tons less than in the September period. The smelter yielded 196,752,631 lb. in 1916, of which 50,723,245 lb. was made in the period under review. Extremely bad weather curtailed operations in December.

The Ohio Copper Co. is treating 2000 tons of 0.9% ore daily. The recovery is 45%, but flotation is being tried. Present profits are \$30,000 per month. The mine contains millions of tons of 0.8% ore.

EUREKA. During 1916 the Chief Consolidated Mining Co.'s development covered 25,844 ft. Results were good, especially at 1800 ft. Ore shipments totaled 83,606 tons, lead ore being 68,961 tons. The metal-content of all ores was 8331 oz. gold, 1,739,004 oz. silver, 18,356,937 lb. lead, 1795 lb. copper, and 790,525 lb. zinc, all a large increase when compared with the 1915 yield. The income from all sources was \$1,601,903. Dividends totaled \$176,481. The balance is \$477,295.

SALT LAKE CITY. The Utah Power & Light Co. reports as follows for 1916: revenue, \$4,342,089; profit, \$2,257,638; interest, \$1,013,300; and surplus, \$1,244,338. The profit was an increase of \$528,914 over that of 1915.

WASHINGTON

CHEWELAH. During 1916 the United Copper Mining Co.'s profit was \$123,706. Gross receipts were \$374,131. Dividends are to be continued at the rate of \$10,000 monthly, equal to 1%. The shaft below the 1000-ft. level is being sunk to 1500 feet.

NORTHPORT. During 1916 the Electric Point Mining Co. made a profit of \$48,753, plus \$45,000 due on 61 cars of silver-lead ore at the smelter. An initial dividend of 1% has been paid. In five months of production the output was 1194 tons of sulphide and 7764 tons of carbonate ore shipped. These are high-grade products.

CANADA

BRITISH COLUMBIA

The following table shows the great value of the Trail smelter to this province, the tonnage of ores received being for 1916:

	Tons
East Kootenay	99,531
West Kootenay:	
Ainsworth division	13,171
Slocan division	16,461
Nelson division	4,792
Trail Creek (Rossland) division	293,409
Arrow Lake division	8
Trout Lake division	120
Revelstoke division	415
Boundary	15,339
Yale:	
Nicola division	553
Ashcroft division	41
Kamloops division	4,531
Vancouver Island	46
Omineca division	766
Alberta	52
Yukon Territory	38
Ontario	444
United States (Washington)	36,971
Total	486,658

This was an increase of 45,063 tons over the 1915 total, due mainly to the East Kootenay district. Rossland fell off over 40,000 tons, while Boundary gained 15,000 tons.

In the February Bulletin of the Canadian Mining Institute, F. A. Thompson of the State college at Pullman, Wash-

ington, gave notes on local treatment of some west Kootenay silver ores. He considers that amalgamation is not necessary, concentration will become necessary with the deeper ores, fine-grinding and strong cyanide solution will treat ore from the Ainsworth district. Concentration and cyanidation yield a high recovery. Erection of plants is not advised unless large quantities of ore are available.

ONTARIO

The report of the Temiskaming Mining Co. for 1916 is to hand, and the general manager, F. L. Culver, includes the following:

The main shaft is within 100 ft. of the underlying contact between the diabase and keewatin formations. When reached, lateral work will be started to prove the existence of ore. The vein system opened late in 1914 still yields large quantities of rich ore. More or less favorable results continue from the old vein system, and there is a large tonnage yet to be extracted. Development in 1916 totaled 5243 ft. On the dumps is 150,000 tons of 4-oz. tailing, and as flotation tests have been successful a plant is to be erected for its treatment. The mill treated 32,897 tons of ore in 309 days, yielding 333,431 oz. of silver. Including metal from high-grade ore the total output was 1,263,848 oz. The cost was 26.4c. per oz. Dividends (3) totaled \$225,000.

The McKinley-Darragh company is erecting a ball-mill to take the place of its 50 stamps. The 100-ton flotation plant is working well.

KOREA

The Seoul Mining Co. reports the following results for the month of January: total recovery of gold, \$118,950. Milling operations stopped for several days during the month because of theft of copper wire from the power-line. A great improvement in prospects is reported, also the same for the Tul Mi Chung mine.

MEXICO

In *The Yale Review* for January 1917, John Barrett gives a review and forecast of Mexico. This was reprinted in the January 'Bulletin' of the Pan-American Union. The position of Mexico gives it a strategic advantage in international trade, especially as it has 5500 miles of coast-line. Geographically and climatically the republic is intended to become the ultimate home of a highly civilized, prosperous, and peace-loving population. Under conditions of peace Mexico can produce practically everything in minerals, metals, timber, and agricultural products which are necessary for the maintenance and prosperity of a great people and nation. The country only has about one-fifth of the railway mileage it actually needs. The Indian and peon classes are not so illiterate as supposed; and the feeling against Americans is not so bitter as frequently published. The necessities that would evolve permanent stability, peace, and prosperity are: (1) Establishment of conditions which will have the confidence and support of Mexicans and foreigners; (2) an enlargement and ramification of the public educational system; (3) improved methods of agriculture; (4) improvement of labor conditions in both industrial and agricultural industries; (5) establishment of new industries that would utilize domestic products, employ local and foreign capital, and so increase the population and progress of the interior; (6) encourage immigration of the right kind from the United States and Europe; (7) investment of foreign capital to help the Government and to develop the country; (8) construction of railroads, highways, telegraph, and telephone lines; (9) mutual acquaintance between Mexicans and Americans to be fostered by travel; (10) study of Spanish and all things connected with Mexico to be undertaken in United States schools; and (11) co-operation between Mexico and the United States to promote the cause of practical Pan-Americanism and to strengthen the solidarity of the American Republics.

PHILIPPINE ISLANDS

MANILA. The Division of Mines, Bureau of Science, has issued its bulletin on the mineral resources of the Territory for 1915. The total value was ₱4,867,586, of which gold was ₱2,633,528; silver, ₱15,665; and non-metals the remainder. In 1914 the total was ₱4,613,391. The gold output during 9 years shows a good increase, as follows from 1907: ₱187,647, ₱434,500, ₱495,194, ₱308,860, ₱379,906, ₱1,140,424, ₱1,736,724, ₱2,349,267, and ₱2,633,528. Both dredging and lode mines are responsible for the gain. Progress during 1916 is discussed by V. E. Lednicky, who also writes on Philippine mining possibilities, the Acupan Mining Co.'s operations at Baguio, and the

iron industry. Dredging is reviewed by F. B. Ingersoll, salt by T. Dar Juan, and coal by F. R. Yeasiano. A new map, from which the one accompanying these notes is reproduced, is included with the report. In the archipelago of the Territory are 1600 islands, many of which contain minerals and many islands are practically unexplored. The Bureau of Science is mapping available deposits, but as geologists are lacking the work is slow. Intelligent prospecting should be encouraged, there being less than 100 real prospectors in the islands. The rank tropical vegetation is a handicap to exploration.

The Philippine government has issued a 25-page press bulletin on industrial possibilities in the Territory. The materials covered are paper-pulp, copra, gums, tanning products, leather, sugar, spirits, oils, rubber, soils, water supply, iron ore, coal, lime, clay, and fauna and flora.

Dwight T. Smith, principal of the VIRGINIA CITY SCHOOL OF MINES reports that splendid progress was made in 1916, when there was an average of 9.4 members per month, against 7.2 in 1915. Over 1000 samples were tested for prospectors.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

JAMES M. PLATT has gone to Peru.
J. R. FINLAY was at Miami, Arizona, last week.
N. M. MUIR has returned from Jarbidge, Nevada.
MORTON WEBBER was at Clifton, Arizona, recently.
W. PELLEW-HARVEY has returned to London from Australia.
FREDERICK W. GAY has gone to New York for about six weeks.

WALTER NEAL has returned to the Amparo mine in Jalisco, Mexico.

F. R. WEEKES is in California, with headquarters at Darwin, Inyo county.

HOWLAND BANCROFT has returned from South America to his office at Denver.

D. C. JACKLING is making a visit of inspection to the Ray and Chino Mines.

WARREN EARL GREENOUGH of Spokane is taking a holiday at Coronado, California.

FRANK LAWRENCE has left San Antonio, Lower California, for a visit to San Francisco.

HIROSHI ABAY, of the Mitsubishi Company, is making a tour of American mining districts.

R. L. FEAGLES, mechanical engineer with the Deister Machine Co., is in San Francisco.

ALGERNON DEL MAR has gone to Siskiyou county to take the management of the Dewey mine.

JAMES NELSON has returned to the Amparo mine, for McKeever Bros., in Jalisco, Mexico.

COURTENAY DE KALB, who has been visiting the Globe district, is expected in San Francisco.

H. W. DARLING has been appointed manager of the Dome Lake mine, at Porcupine, Ontario.

FREDERICK HELLMAN was in San Francisco this week, and is now on his way back to New York.

ETIENNE A. RITTER, of Colorado Springs, passed through San Francisco on his way from Oatman to Colorado Springs.

GEORGE W. GOETHALS announces that he has opened an office as consulting engineer at 43 Exchange Place, New York.

CECIL GORE-LANGTON, recently at Owen's Lake, has obtained an appointment on the staff of the Inspiration Consolidated, at Miami, Arizona.

E. J. SCHRADER has fully recovered from an operation performed at Lane Hospital, San Francisco, in December, and is back at Rockland, Nevada.

M. W. VON BERNEWITZ has left the MINING & SCIENTIFIC PRESS, and is now available for a vacancy at any metallurgical works, or in a consulting capacity.

J. O. GREENAN, recently with the exploration department of the Goldfield Consolidated, has been appointed superintendent of the Olympic mine, at Mina, Nevada.

E. P. MATHEWSON has been awarded the gold medal of the Mining and Metallurgical Society of America in recognition of his achievements in non-ferrous metallurgy.

W. F. M. GOSS, for many years associated with the schools of engineering of Purdue University, and since 1907, Dean of the College of Engineering of the University of Illinois, has resigned that office, effective March 1, 1917, to assume the presidency of the Railway Car Manufacturers' Association.

W. N. THAYER recently returned to Cincinnati, Ohio, after making an examination of oil-land in south-western Kentucky. The good results made by the Estill County field last year have stimulated prospecting, chiefly of the wild-cat type. A few operators are working under the direction of geologists.

THE METAL MARKET

METAL PRICES

San Francisco, February 20.

Antimony, cents per pound	24
Electrolytic copper, cents per pound	36
Pig lead, cents per pound	8.75-9.75
Platinum, soft and hard metal, per ounce	\$105-111
Quicksilver, per flask of 75 lb.	\$140
Spelter, cents per pound	12
Tin, cents per pound	47.50
Zinc-dust, cents per pound	18

ORE PRICES

San Francisco, February 20.

Antimony, 50% metal, per unit	\$1.50
Chrome, 40% and over, f.o.b. cars California, per ton	18.00-20.00
Magnesite, crude, per ton	8.00-10.00
Manganese, 50% (under 35% metal not desired)	16.00
Tungsten, 60% WO ₃ , per unit	17.50-18.00

New York, February 14.

Tungsten is unchanged at \$17 per unit, molybdenite at \$1.80 per pound for 90% concentrate, and antimony ore at \$1.85 per unit.

EASTERN METAL MARKET

(By wire from New York.)

February 20.—Copper is strong but quiet. Lead, if nearby, commands a premium. Spelter is quiet and spot metal is scarce.

COPPER

Prices of electrolytic in New York, in cents per pound.

Unremitting demand from abroad, together with the additional scarcity of supply created by unsettled shipping conditions which have seriously interfered with shipments out of New York, are factors to which are attributed the steadily rising silver market of the last few days.

The cessation of sales from China and the paucity of supplies from America have imparted steadiness to the market. At one time the entry of Indian Bazaar buyers to cover bear sales caused an apprehension that the price might be forced up considerably, but when 37½¢ was reached on January 22 competition eased off.

The issue of a sterling loan in India may attract some rupees

into the Treasury. It will be interesting to see whether sales of gold will have any effect upon the Indian currency figures.

On December 8 the following enactment was made in Hong-kong: "Rule 37. No person shall export without special permission of the Superintendent of Imports and Exports or attempt to export, or procure for the purpose of exportation, any silver dollars or silver bullion."

Tin is firm at 50 cents.

ALUMINUM

The quotation for No. 1 virgin aluminum, 98 to 99% pure, is unchanged at 57 to 59¢ per pound. Trade is hampered by the difficulty of making deliveries.

PLATINUM

Price of platinum, New York, is \$105 per ounce for soft metal and \$111 for hard.

Eastern Metal Market

New York, February 14.

Uncertainty as to the outcome of this Nation's attitude toward Germany, the general difficulty of making shipments and getting deliveries by rail, and the handicap imposed by severe cold weather are influences which have made the metal markets quiet in the past week. It is as difficult to obtain raw materials as to make shipments of finished products—a condition which disturbs every industry.

The copper market is almost at a standstill except for occasional sales of small lots of spot at fancy prices. Copper is extremely strong, and there is every indication of its remaining so.

Zinc is firm. The curtailment of its production probably will be felt later.

Of all the metals, lead seems to be the hardest hit because of delays in transportation. Spot lots are selling for 9c. and over, St. Louis. The A. S. & R. Co. quotes 8.50c., New York.

Tin is arriving freely, and the recent scare has been discounted to such an extent that prices have dropped 2c.

Antimony has been sold at 30c. per lb. in the week. Spot is scarce. Aluminum is steady.

The breaking down of the railroads, for that is what it amounts to, with a consequent failure of deliveries against contracts is creating a spot market for all sorts of products at premium prices. Pig iron is quoted at eastern Pennsylvania furnaces at \$31 to \$33 per ton for foundry grades. At Buffalo \$35 is asked for No. 2X. Steel-making grades are strong, but do not show such an active tendency to advance. As a result of the cold and insufficient transportation, about 25% of the producing capacity of the Central West in pig iron and steel is idle. Of the Steel Corporation's furnaces about 30 are out of blast. The situation with regard to Germany does not seem to have lessened the demand for iron and steel products; on the contrary, with many mills, additional specifications have been received, mostly from consumers who fear that the United States government may commandeer a good part of the capacity of the mills. The railroads continue to place equipment orders at a lively rate.

COPPER

The market is strong, but there is very little doing. Buying is confined almost entirely to small lots of re-sale metal that are taken only because of the urgent needs of a few consumers whose operations are limited. It is estimated that all the business of the past week does not exceed more than 1000 to 1500 tons. Under these circumstances, sellers find it easy to obtain premiums from the buyers. Late last week, some spot was available at 34.50c., cash, but to-day that is about the price for March. It is reported that small lots of spot brought 36c. The producers have made it clear repeatedly that they have no first-half metal to sell, and now it appears that some of them are not anxious to sell for July delivery. They prefer to wait and see where political events will lead, and, so far as possible, to keep themselves in a position to care for the Government's requirements should these become abnormal. The nominal quotation for second-quarter copper is between 32.50 and 33.50c. The export situation is a rather puzzling one. It is estimated that copper should be going abroad at the rate of about 90,000,000 lb. per month, yet exports are far from that level. In January, for instance, the exports were only a little over 57,000,000 lb. and so far this month (Feb. 1 to 14) they total only 26,250,560. One plausible explanation of the showing is that large quantities are being shipped to American manufacturers of munitions to be applied against foreign orders. Amid all the conjecture, one thing is certain, and that is that the metal is as strong as it was prior to the re-

cent peace talk which smashed the market. The London quotation for spot electrolytic yesterday was £147, or £1 higher than a week ago.

ZINC

All interests, on both the buying and consuming sides, show a tendency to await developments; consequently the market has been quiet during the past week, but quotations are firm at slightly higher levels than prevailed a week ago. Prompt prime Western was quoted yesterday at 10.75c., New York, and 10.50c., St. Louis. March is around 10.50c., New York, and at St. Louis, about 10.25c., with second quarter near 9.75c., St. Louis. Brass mill special is 1 to 1½c. over these prices. Severe weather in the West continues to restrict production, an influence which sooner or later will be felt in the market. The London quotation for spot, as compared with a week ago, was unchanged yesterday at £47. The exports, Feb. 1 to 14, total 4524 tons. Sheet zinc is unchanged at 21c. per pound f.o.b. mill, 8% off for cash.

LEAD

Uncertain and long-delayed railroad deliveries from the West continue to hold spot lead at high levels, considerably over 9c. having been paid. An occasional carload gets through, but the arrivals are not sufficient greatly to relieve the situation, and the law of supply and demand rules. On February 8, a lot of 500 tons of February lead was taken by a consumer at 9c., St. Louis, and even early March shipment at this level. No relief is in sight. The A. S. & R. Co. advanced its quotations \$10 per ton, February 9, making its price per pound 8.50c., New York and 8.42½c., St. Louis. Although it is reported that the leading interest has made sales to some of its large and regular customers at the new prices, the general understanding is that the company's quotations are more generally used in monthly settlements on an average basis. The exports, February 1 to 14, total only 330 tons. The London quotation for spot yesterday was unchanged at £30 10s., as compared with a week previous.

TIN

The week has been quiet. Fear over the possible loss of cargoes through the activity of submarines has been discounted to such an extent that prices have declined about 2c. in the past week. Spot Straits was quoted yesterday at 53c., New York, whereas a week ago it was 55c. An interesting phase of the situation has been the wide difference between Straits and Banca—2½ to 3c. Arrivals in the past two or three days have been larger than were expected, especially of Banca. Arrivals of the month total 1525 tons, and there is afloat 3498 tons. Large quantities are likely to turn up unexpectedly because of the meagre information available relating to sailings from the other side.

ANTIMONY

Reports have been published of extremely large buying for munitions purposes, some of it being credited to providing for possible future requirements of the United States government, but the trade is skeptical about such buying, and construes the reports as an effort to boost the market. More or less of the supposed desired result has been attained, inasmuch as spot Chinese and Japanese antimony is quoted at 28 to 30c., duty paid. The trade, however, credits the strong position of the metal rather to the short supply than to any other cause. There is no question but that shipments from the Pacific Coast have been greatly delayed, while another influence making for a higher market is faulty cable service with the Far East, which interferes with business.

EDITORIAL

T. A. RICKARD, Editor

WE publish a most interesting letter from our Mexican correspondent.

CCOURTENAY DE KALB has become Associate Editor of this paper.

WEST AFRICA produced less gold in 1916 than in 1915 or 1914. The total was 389,068 ounces, worth £1,615,306 or \$7,834,234. The decrease, as compared with 1915, is \$442,159. The Ashanti Gold Fields company continues to be the chief producer of gold in this region.

TO see ourselves as others see us is a stretch of philosophic imagination that has been commended by cynics, and by others better natured. It is one way to learn. We take pleasure in publishing the notes of a metallurgical engineer from foreign parts that recently visited the principal reduction plants in Arizona, Colorado, and Montana. His review was not intended for publication and is therefore all the more interesting.

REFERRING to the Freeman process, invented by C. A. Freeman, we are able to state that a 3 to 10% solution of soda-ash, or carbonate of soda, is used for floating preferentially the galena in Broken Hill ore without the aid of oil. Subsequent use of oil serves to separate the zinc-blende from the tailing. Any copper in the ore is floated in the first, or leady, froth, which is cleaned in a potassium bi-chromate solution, so as to recover both the copper and the lead in the form of a marketable concentrate.

A BILL is pending before the Nevada legislature for an official inspector of shipments of ore to smelters and other custom reduction works in the State. Besides the chief inspector, the bill provides for a staff of five assistants. Obviously the creation of this new office represents an effort to protect the small shipper and to insure a square deal for all parties concerned in the sale, purchase, and treatment of ores. Whether it will accomplish much in harmonizing the constantly recurring differences between ore-shippers and the custom-reduction works is an open question. "For ways that are dark and tricks that are vain" the smelters and sampling-works people in Nevada "are" not "peculiar."

ONE man's food is another man's poison. While millions have been beggared by the War, it has been the good fortune of a few to make tremendous gains. E. I. du Pont de Nemours & Co., the famous powder business, earned \$82,107,693 net in 1916, and \$57,840,-

758 in 1915, as compared with \$5,603,153 in 1914. This has been done by the expenditure of \$60,000,000 in plant construction, but the new capital has been already amortized. In 1916 the company earned 133.31% on its \$58,854,200 common stock, after paying \$3,648,222 as interest on its debentures. On December 31 last the cash balance was \$82,325,103 and in 1916 the gross sales amounted to \$318,845,685. Even after War is over, this company will be a big industrial factor, for it will utilize its big equipment for other useful purposes.

PATENTS granted in the United States during the week ended February 13 made a total of 930; of this number probably not 5% will ever be commercially successful. The report of the Commissioner of Patents, Mr. Thomas Ewing, covering the work of the Patent-Office during 1916, has been issued. Out of 71,033 applications for patent of all kinds, 45,927 were granted. These figures exclude designs, trade-marks, and the like. The Department received \$2,343,541 from all sources, and spent \$2,115,368; therefore the Patent-Office was operated at a profit of \$228,173 and the average cost per patent was \$46. The scientific library was enriched by only \$2306 worth of books. The defense of suits cost \$567. The average time that successful applications had to wait for patent was 21 months. The building is over-crowded, and conditions are growing worse. The latest patent is No. 12,162,516.

LABOR-UNIONS are useful, and even necessary, for the protection of employees in many industries, but the stupidity of some of their performances passes belief. Suddenly, not many days ago, the 24 crane-men and 58 electrical-workers at the Anaconda smelter laid down their tools and walked out. Was it because they had an insufferable grievance against the company? Not at all. Their hours and wages were most satisfactory. No, they had a quarrel with the mill and smelter-men's union. It appears that the smelter-men's union and the electrical-workers' union alike claimed 'jurisdiction' over the crane-men. Some of the latter did not pay their dues to the smelter-men's union, which then called upon the company to dismiss them, according to agreement with the union. But the electrical-workers' union insisted that the crane-men should be re-instated and when the company could not please them also, they walked out. A pretty kettle of fish! The Anaconda company has asked the American Federation of Labor, to which all the contending parties belong, to settle the trouble. Unless better sense is shown, and the unions respect their own

agreements, the company will be warranted in adopting the open-shop system. That would be a step backward from the employees' standpoint, and possibly from the employers' also.

SIMPLEEFIDE SPELLUN was the subject of a recent meeting at New York, in which representatives of several technical societies participated. Among others the A. I. M. E. was represented. Hence our interest in the matter. At the close of the meeting sundry spellings were adopted and others rejected. Many of them are already in vogue, others never will be—thank Heaven! Several rules on hyphenation were passed, but all that need be said about them is that they disclose ignorance of the function of the hyphen. Why discuss hyphens with people that write 'to-day'? The idea of settling such matters by the vote of the editors of the technical societies and of publishing houses is based on a fallacy, namely, the notion that the publications of either one or the other are in the hands of literary men keenly interested in the niceties of spelling or style. The opinion of an experienced writer, like Dr. Raymond, is worth that of a roomful of non-literary technical men. The present secretary of the Institute is a most efficient executive but unless we are much mistaken he does not care about the minutiae of writing, nor has he the time to attend to them; certainly the papers published by the Institute owe more to their authors and to providence than to the editing they receive, if we may judge by the wide variation in the amount of revision that we find necessary before they appear in our pages. The meeting to which we refer agreed to ascertain the usage adopted by a number of organizations, some of which have a style that like Topsy "just grewed up" anyhow. They would do well to consult one of the most conscientious and intelligent of technical critics, the editor of the U. S. Geological Survey.

AMONG the commendable regulations of the New York Stock Exchange is the one compelling disclosure of the business of a company when it seeks to list a new issue of shares. To this regulation we owe some interesting information. For example, the Cerro de Pasco Copper Corporation, a Hearst-Haggin enterprise in Peru, has been persistently secretive concerning its operations since it started in 1902. Now, on asking for 666,666 new shares to be listed, the corporation has had to make a detailed statement. This shows that it controls the Cerro de Pasco Mining, the Morococha Mining, and the Cerro de Pasco Railway companies, and from them it obtained the income of \$3,420,000 earned in 1916. The ore in reserve in the parent mine is estimated at 3,000,000 tons containing 253,452,000 pounds of copper and 21,745,000 ounces of silver, that is, the ore averages about 4.2% copper and 7 oz. silver per ton. Of the total smelter production, 40% comes from Cerro de Pasco and 60% from Morococha. Besides the main supply of copper-sulphide ore, estimated to last for 10 years, there is a large quantity of oxidized low-grade silver ore—8 to 30 oz. per ton—that is not in-

cluded in the assured reserves. The company owns two large coal mines. From 1908 to 1915 inclusive the smelter returns, including those from custom ore, amounted to \$64,300,000, of which \$50,000,000 represented copper, \$11,000,000 silver, and \$3,300,000 the gold content. In those eight years the smelter treated 2,358,000 tons of ore and produced 340,000,000 pounds of copper, an average of 7.2%, and 19,802,000 ounces of silver, an average of 8.4 ounces per ton, besides 154,200 ounces of gold. The expansion of the Cerro de Pasco output has synchronized with the War, the production of 1914, '15, and '16 having been 43, 60, and 70 million pounds of copper respectively.

DISCUSSION this week begins with a timely letter from Mr. Howard D. Smith on the sampling of the immense low-grade orebodies now being exploited near Juneau, Alaska. Mr. Smith is particularly well qualified by his experience to attack the problem. Our comment is deferred until next week. Mr. H. M. Wolfen, of the U. S. Bureau of Mines, gives information concerning the law regulating the action of employers and employees in the matter of safety underground. Mr. R. T. Hancock writes from a distant mining district, in Nigeria, to suggest a rapid method for determining the tungsten in a mixed concentrate. We thank him for it. Our recent editorial on the supply of cyanide has drawn a letter from the American manufacturer of that chemical, Roessler & Hasslacher. It will be good news to many of our readers to learn that an ample supply is promised by July and that no attempt is being made by the manufacturer to raise the price—this unpleasant result of the existing scarcity being attributable to enterprising middlemen. An anonymous reader objects to our recent dicta on short-selling and contributes a story that has point. The gambler in the story made a bet on the stock-market and called it a mining venture. Mining has to carry the blame for many such 'flyers.' They are nearer related to Monte Carlo than to Montana. Mr. E. Coppée Thurston, an engineer recently a helper on the Belgian Relief Commission, endorses the appeal for funds and urges us all to support the good work. Mr. Storms makes an interesting observation on the association of magnetite with copper-sulphide ore. Mr. John A. Roos tells us how to get rid of a headache caused by 'powder-smoke.' Professor Weeks comes back to the discussion of misfires and makes an excellent suggestion regarding primers. Our recent article on milling practice at the Nickel Plate mine has elicited some useful supplementary remarks from the superintendent of the mill, Mr. Roscoe Wheeler. He gives additional data concerning the agitator that he uses in the cyanide plant. Mr. Henry Mentle, manager for the Snake River Mines Company, gives some practical hints on stamp-milling, based largely on his experience at Cornucopia, Oregon, whose heavily pyritic ores have run the gamut of metallurgical treatment, from simple stamp-milling, through roasting, to cyanidation, besides several side-steps. Mr. Reuben Yost—with the accent on the Reuben—tells of using machines for unsuitable purposes, and the results.

Finally, an 'old-timer' records his protest against the suggestion to substitute a money-payment in lieu of assessment work on locations.

A Mexican Constitution

In Mexico there is a brand-new constitution. Liberal extracts from it appear in a letter from our Mexican correspondent. To some unfortunate investors, whose property happens to lie within those portions of Mexico dominated by the long-whiskered First Chief, this document must needs be taken seriously. It profoundly affects the *status quo*, considering that it has become the acknowledged policy of our Government to ignore the treaty-rights of our citizens. The regulation set forth in the first sub-section of Carranza's astounding State paper declaring forfeit the property of any foreigner who may invoke the support of his own government for the protection of his rights under a special concession from Mexico, is a step forward in arrogance, constituting a virtual disregard of the commercial conventions between this country and the Mexican Republic. Had our relations with Carranza's government been conducted in the customary manner through a duly accredited embassy, this attempted invasion of guaranteed international privilege would have been made immediately the subject of serious protest to the Mexican executive. Failure to obtain proper assurances for the observance of our treaty-rights would have led to a rupture of diplomatic relations, and to a state of mutual suspicion and reprisal possessed at least of the merits of sincerity and comprehensibility.

At the present time we are technically at peace with Mexico, we technically possess treaty-rights in Mexico, our nationals technically enjoy privileges of commerce and property-tenure in Mexico, yet collectively and individually the American people is solemnly admonished by our State Department to keep out of that country. Is the tardy sending of a diplomatic representative from Washington to Querétaro, or to whatever safe retreat the First Chief may select, intended as a means for bringing the pitiful farce to a conclusion? We venture this as a last hope in the ultimate good sense of our Administration. In the usual course of diplomacy justification for the recall of Ambassador Fletcher will quickly enough be found. That will be the end of the whiskered pomposity who has hurled more insults at this Government than it has received from all other sources throughout its entire previous history. Unsupported by the Administration at Washington, Carranza's tottering government must speedily fall. Not even his bill of anarchistic license, termed a 'constitution,' can save him. It does not express the will of the Mexican people. It expresses ostensibly the principles of Magonism, as proclaimed in the reeking pages of *La Resurreccion*, while craftily it sub-serves the interests of *científicos* like Carranza and his intimates, who espoused the cause of the so-called *Constitucionalistas* as a clever ruse for avoiding the confiscation of their own estates. Carranza has deceived a

few of his countrymen, but not many. His direct followers represent a herd, contented while he throws corn into their mangers, but ready to transfer their allegiance as soon as a new leader demonstrates that he can feed them equally well. The great mass of the Mexican people, quiet, law-abiding by nature, seeking an independent existence as petty rural proprietors, is watching for the joker in the new constitution. It must promptly appear to anyone who reads the extracts printed in our Mexican correspondence. In great detail it is there stated how the dispossessed heirs to communal estates may come into their own again. In the days of the grafting *caciques* the laws made it singularly easy to ignore both justice and equity in acquiring titles, by due process of law, to estates that all the world knew belonged in reality to the lowly workers born upon the soil. Señor Carranza could furnish an explanation of the process in its minute and harrowing details, as exemplified in the absorption of certain rich principalities in Coahuila that he has not yet relinquished to the poor. The new constitution purports to undo all this mischief of the *científicos*, which is the basis of the revolution. The civil strife in Mexico may have been set going by competitive oil-engines, but a real grievance must underlie a popular movement of this sort when it is sustained by a characteristically litigious nation. The grievance was the robbery of the lands from the common people. Agrarian reform has been the watchword of the revolution. Let anyone give honest dependable agrarian reform, and the revolution will cease. The malcontents and trouble-makers could then in very truth be denominated 'bandits.' At the present time they are entitled to be called revolutionists. There is something to revolt against in the face of this Carrancista 'constitution.' It provides no scheme of reform; it gives no guarantees; the reforms in the end, as our correspondent shows, are dependent upon 'executive decree.' Though they may be defined and prescribed in this farcical document, and amplified by State and Federal legislation, the initiative rests with the executive, and there is no appeal to the courts. The judiciary is empowered merely to fix the amount of compensation to the former owner of record, after the executive has set in motion the machinery of expropriation for the benefit of the poor. Will Señor Carranza set this machinery in motion against his own great estates? Does it appear that Señor Carranza intends to let the poor obtain relief when he so cleverly arranges to hold the reins of justice in his own arbitrary hands?

We repeat that this entire ridiculous pretense at 'reform' is not to be taken seriously except in so far as it affects a few unfortunates who are still trying to do business under Carranza's administration. The Querétaro 'constitution' itself is unconstitutional. The Constitution of 1857 prescribed the way in which it might be amended, and Carranza has paid no heed to that detail. Carranza protested against the alleged violation of the Constitution of 1857 by Huerta; he rode into power as the head of the Constitutionalist party, defending the sacred instrument which he now coolly sets aside,

and none of whose mandates he has respected. Why has he not chosen to first legalize his own position under the document he championed, and then accomplish reforms by constitutional amendment or by statute? The fact is that, in following the straight and narrow path, the prize of the presidency might elude him. Either during the period of a presidency *ad interim*, or as subsequent elective president, the executive control must pass out of his clutches. He has no safe stool-pigeon in sight. To retain his power he must dodge the Constitution of the Republic; hence he places himself today in an unconstitutional position. His government is not the government of that Mexico with which we have treaty relations; he actually administers only a fraction of the country and cannot by any possibility be considered either *de jure*, or *de facto*, ruler of Mexico. The document which his minions wrote at his dictation at Querétaro is likely to be the cause of his undoing. Instead of justifying his defiance of the fundamental law of Mexico, it is certain to disgust every man who hopes for reform at home, and to bring diplomatic disaster through its infraction of the rights of foreigners.

A Technical Conversazione

The group of gentlemen in New York that call themselves the Mining and Metallurgical Society of America have the pleasure of meeting at monthly intervals, and when they do so they say much that is interesting. For instance, the discussion recorded in the latest bulletin of the Society was devoted to the effect of the existing abnormal conditions on the cost of mining and smelting operations. Mr. Sidney Jennings emphasized the foreign origin of run-of-mine labor. "The mining of ore in the United States is done almost entirely by foreigners." At the mines with which he was connected, 27 different nationalities were represented. The War did not call many of them away—no such proportion, we presume, as went from the Canadian mines to the trenches in Europe. Those that have been working steadily at current wages are accumulating a fortune, and when peace is restored many of them will return to their native land. Mr. Judd Stewart quoted statistics showing that in normal times 30 to 40% of all immigrants return to their home-country. When the War is over, he said, an exodus of labor to Europe will follow, and the shortage will be acute. Mr. M. B. Spaulding, the chairman of the meeting, mentioned the fact that the passenger-space on the big German boats interned in New York harbor had all been engaged by those awaiting the chance to re-cross the Atlantic. As regards the increased cost of labor, Mr. Jennings stated that wages now were 60% higher than three years ago. Mr. Walter Douglas gave the rise as 48% for all-white labor at Bisbee and 70% for mixed labor at Morenci, as compared with 1914. Mr. J. Parke Channing estimated the increase at 55% as compared with the early part of 1914. As labor represents about two-thirds of the total cost of mining, it is apparent that the principal economic factor has changed greatly, and

yet without disastrous effect. Most of the engineers present agreed as to this, although Mr. H. H. Alexander, referring to lead refining, asserted that, in his experience, common labor shows a decrease in efficiency ranging from 25 to 30%. This did not apply, he added, "to the steady labor, furnace-men, helpers, and that class, who have been long on the job. They are doing as much work as ever." Likewise Mr. F. R. Pyne thought that the efficiency of labor had declined "20 to 30 and 40%." Mr. Channing, however, stated that efficiency at Miami had not been affected by higher wages, "so that the tons per man per day remain just about the same as they were in the early part of 1914." Mr. L. D. Ricketts said, while in San Francisco, that although the average pay at Inspiration was \$5.40, the cost of mining was only 61 cents per ton, each man breaking 16 to 18½ tons per shift. On the whole, it is fair to conclude that skilled labor has been stimulated to better effort by reason of higher pay. Mr. H. H. Stout testified that when an increase of wages was demanded and obtained by a strike the efficiency declined as much as 28% for a few months, but when an increase was conceded before it was demanded, so that it became "more or less of a surprise," the efficiency of the men rose about 12%. Mr. George C. Stone complained of the scarcity of skilled furnace-men in zinc smelting, owing largely to the great increase in the number of plants. Mr. W. R. Ingalls stated that the cost of labor for smelting zinc ore had doubled, while material of every kind was two to three times more expensive. He estimated the total cost of smelting at \$16.53, as against \$8.25 before the War, exclusive of the cost of natural gas as fuel, which had risen enormously. At Miami the cost of producing copper rose only half a cent per pound in 1916 as compared with 1915, so Mr. Channing stated. All of the refiners complain of the increase in the value of the metallurgic losses owing to the higher price of the metals themselves. A touch of humor, however, is not wanting in the plaintive tone of these speakers, all of whom are connected with, or themselves participating in, large-scale mining and metallurgic operations of a most profitable kind—of a kind that has been highly benefited by the set of conditions on which they were animadverting. It is noteworthy that most of these captains of industry did not fear trouble when wages have to be reduced in consequence of the inevitable market reaction at the end of the War. In this pious expectation they seem to us sanguine. Mr. H. H. Stout suggested that where the sliding scale is in vogue the payment to workmen should be made in two checks, so as to emphasize the meaning of the bonus, as an excess-payment due to temporarily high metal-prices. One other note may be made, namely, that the relatively small increase in cost of production, despite higher wages, is not wholly due to better organization or to improved mechanical devices, but is traceable largely to more expansive mining, stopping of reserves, and general growth of tonnage in order to make the most of a favorable market. The day of reckoning is inevitable. After this orgy of production will come the need for sober development.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Sampling Low-Grade Orebodies

The Editor:

Sir—The question you addressed to Mr. John H. MacKenzie, concerning the sampling of orebodies such as the Alaska Gastineau, brings up a subject that has been obscured in recent years. It has become the custom to ascertain the gold-content of such orebodies by milling considerable tonnages, usually taken from a few places, or, as in the case of the Alaska Gastineau, from only one part of the mine. It is reported that in this case an error arose through the tonnage being under-stated and the recovery consequently over-stated. Plainly the same caution must be taken in accepting mill-returns for their face-value as in case of moil-samples.

Despite your own long experience and valuable book on sampling, you, Sir, have held forth at times on the impossibility of arriving at conclusions of value by sampling certain orebodies. I can hardly believe that such views are seriously held, but rather that they are put forth by you to stimulate controversy and thereby to elicit useful discussion.

Gold is known to be distributed erratically, therefore it is contended that samples should be taken on a milling scale in the case of large low-grade gold deposits. Because of their size, the question of what they represent is sometimes lost sight of. The effort to handle a large tonnage is apt to result in getting mere grab-samples on a grand scale. Many sections properly placed must be cut across the orebodies, as when moiling samples, and, of course, every care must be taken to guard against salting or other sources of error.

Objection is made that the amount of work and expense incidental to thorough sampling is prohibitive on such a property as the Alaska Gastineau. The cash outlay on this mine has been, I understand, in excess of \$7,000,000. Two per cent would not be an excessive proportion to spend on essential sampling. With a sum of \$140,000 much additional information could have been obtained. The matter of keeping results from different samples separate is much simplified in this case, as the product is wholly in the form of a concentrate, readily cleaned-up instead of coming partly as amalgam on copper plates and partly as other mill-products.

The plant used should be specially arranged. Everything milled should first go through the sampling equipment and an automatic tailing-sampler should be constantly in use.

It goes without saying that only a competent engineer

can direct such extensive sampling work. Questions of how much waste will be broken with the ore in stoping are most important. The time to determine this is when sampling is in progress. Check-samples must be taken, especially where doubt exists. Many should also be taken with the moil. Such samples, if properly taken and sufficiently numerous, will give valuable results as to grade and definite information concerning the distribution of the gold. Whether all samples should be taken with the moil must be determined by the particular condition obtaining in the mine. Doubtless promoters will continue to urge that their milling samples are more conclusive than the careful sampling done by competent engineers.

It is not contended that the last word as to grade is always obtained by hand-sampling, but any deviation from the sound view that an essential element in systematic mining is thorough sampling cannot be too strongly refuted.

HOWARD D. SMITH.

San Francisco, February 16.

Contributory Negligence

The Editor:

Sir—In your issue of January 27 I find a letter under the title 'How About Contributory Negligence' signed by 'Mine Operator.' It appears that the writer of this letter is under some misapprehension concerning the state of the law and the exercise of power vested by the law in the Industrial Accident Commission, governing the matter of safety in the conduct of mining operations underground, with particular reference to the penal provisions of the law for the infraction of the provisions of the Workmen's Compensation, Insurance and Safety Act, section 55 of which is as follows:

"Sec. 55. No employee shall remove, displace, damage, destroy, or carry off any safety-device or safeguard furnished and provided for use in any employment or place of employment, or interfere in any way with the use thereof by any other person, or interfere with the use of any method or process adopted for the protection of any employee in such employment, or place of employment, or fail or neglect to do every other thing reasonably necessary to protect the life and safety of such employee."

Section 67 of the same law is as follows:

"Sec. 67. Every employer, employee, or other person who, either individually or acting as an officer, agent, or employee of a corporation or other person, violates any safety provision contained in sections 52, 53, 54, or 55

of this Act, or any part of any such provision, or who shall fail or refuse to comply with any such provision or any part thereof, or who, directly or indirectly, knowingly induces another so to do is guilty of a misdemeanor. In any prosecution under this section it shall be deemed *prima facie* evidence of a violation of any such safety provision, that the accused has failed or refused to comply with any order, rule, regulation, or requirement of the Commission relative thereto and the burden of proof shall thereupon rest upon the accused to show that he has complied with such safety provision."

It will be seen that there is not only a prescription for safety and safe conduct but also a drastic penalty for violation, with a presumptive proof of guilt available if the man charged with the offense has violated any of the thoroughgoing rules laid down for his government in the 'Miscellaneous Rules for Underground Men' set forth in section 16 of the 'Mine Safety Rules' at pp. 25-32. Men working underground are required to read these rules, or have the rules read to them, and agree to be governed by them, and to evidence this the signature of the employee is required.

The Industrial Accident Commission has had the benefit of co-operation on the part of both mine-operators and miners. Such co-operation must be sustained and persistent if the best results are to be obtained. There can be no question that the law and the rules of the Commission afford a working basis to accomplish measurable safety in mining operations.

H. M. WOLFLIN.

San Francisco, February 5. Chief Mine Inspector.

Determination of Tungstic Oxide

The Editor:

Sir—The article in your issue of July 1, 1916, is of special interest to me, as the method therein described is based on the same principle as one I introduced into this district for the rapid determination of cassiterite or tin metal in samples of alluvial concentrate where the impurity was ilmenite. As now extensively used here it has the advantage of requiring no knowledge of chemistry or mineralogy and can be used by anyone.

In a mixture of two minerals, the percentage of either present, or of a metallic element or molecular group in either, can be expressed in terms of the reciprocal of the specific gravity of the sample, that is, of its 'extensity.' Taking the assays and specific gravities given by your contributor, I find that for tungstic oxide, WO_3 , the appropriate formula is:

$$\text{the per cent } WO_3 = -305x + 116$$

It follows from this formula that if 305 grams of the sample are taken and its replacement in cubic centimetres measured, a replacement of 116 cc. indicates pure quartz or zero tungstic oxide, and that every cc. less than 116 which the sample occupies indicates that it contains 1% of tungstic oxide.

The determination is conveniently made by pouring

the weighed sample into a burette partly filled with water, and noting the reading at which the water stands before and after the addition of the sample. As 305 grams is an inconveniently large sample to take, the quantity may be cut down to half this, when 58 cc. will be the zero and every half cc. less will mean 1% of tungstic oxide. This quantity is within the compass of a 50 cc. burette on high-grade ores, but for very low ones perhaps the weight should be halved again.

As a practical example, assume the method being used in a mill to control the dressing of the product to a 60% grade. Such a product will replace 58 cc. less 30 cc., or 28 cc. First fill the burette with water to the 20 cc. mark and add the 152.5 gram sample. If this goes 60% tungstic oxide the water will stand at 2 cc. in the burette after the addition. Any variation either way can be read from the 2 cc. as 60% and 2% worse for every cc. more.

I should add that this only applies to wolfram and the allied iron-manganese tungstates. Scheelite needs a different formula.

R. T. HANCOCK.

Jemaa, Northern Nigeria, December 17, 1916.

The Supply of Cyanide

The Editor:

Sir—Referring to the remarks in your issue of February 3, we beg to say that our cyanide factory was established in 1890, and since the introduction of the cyanide process in this country for gold and silver extraction we have supplied the greater portion of the demand for cyanide required for this purpose in the United States.

With the growth of this country's consumption we gradually increased our production. This production continued to grow until the Dingley tariff bill placed cyanide on the 'free list,' after which time the increased demands for mining, fumigating, and industrial purposes were shared by imported cyanide, coming principally from Germany. This condition continued until the beginning of 1915, when importations from Germany were prohibited by the British order in council. England could not produce more than its own requirements, and thus with several thousand tons of cyanide bought and paid for, held in Germany, we were caught quite unprepared to meet this country's requirements.

When this situation developed we immediately started on the enlargement of our raw-material plant at Niagara Falls, increasing as the supply of machinery and raw material permitted us to increase, the latest addition to the Niagara works having just been completed. With this increased production we would have been enabled to meet all requirements. However, the Canadian government late last year claimed the greater part of the power supplied by the American power-companies located on the Canadian side, from which source the larger part of our power was drawn, and this unfortunate condition has created the present shortage in our supply.

Immediately upon the Canadian government's inter-

ference we started the construction of a factory for raw materials at another point, and expect this new source of supply to be running beginning with July, when we will be in position to take care of all demands made upon us.

It has always been our policy to keep the price of cyanide at a low level. In spite of being confronted with very many obstacles, the only increase in price that we were compelled to enforce has been an equivalent of the advances which we were forced to meet in raw material, power, labor, and every other element that enters into the production and packing of cyanide. With the decreased production of raw material at Niagara Falls this also affects the selling price, and yet today our price stands at 28 to 30 cents per pound for cyanide of sodium, which before the War we held at prices ranging between 19 and 22c. for the running pound.

As stated above, we expect to be prepared to supply every demand made upon us, by July 1st, and so much the better if this date can be anticipated.

ROESSLER & HASSLACHER CHEMICAL CO.

New York, February 8.

Short-Selling

The Editor:

Sir—The editorial under this title in your issue of February 17 'reminds me' of an experience of a friend, but first permit me to say that I do not agree that short-selling is iniquitous, dishonest, or piratical, as suggested in your editorial. To me the whole scheme of speculation in the stock-market is nothing more nor less than a gamble as to what the other fellow will do. Too often—generally—the real value of property represented by the stock dealt in is not considered at all, the principal factor being whether a large demand for stock will cause the shares to advance in price or heavy selling force the price down? The fellow who can guess right most frequently will become a millionaire.

In 1906, when copper was at 26 cents, and copper-mine shares were high, a friend of mine was urged to 'get in.' He was not a devotee of the stock-gambling game, though a successful speculator in other lines. He decided to investigate and proceeded to 'read up' on copper. He found the metal to be, as he expressed it, "abnormally high," and concluded that the high price could not be maintained. "A drop in price of the metal," he argued, meant "a drop in the market-value of shares." His reasoning was correct. He sought a suitable medium for his purpose and found it in Amalgamated Copper. He then patiently waited for the anticipated drop, and he had not long to wait. At the first break in price of copper, Amalgamated slid down from somewhere around \$100 per share to about \$95. My friend ordered his broker to sell a thousand shares of Amalgamated Copper—shares that he did not own, therefore a 'short' sale. The price of the metal continued to decline and so did Amalgamated. At every five-points drop, as the stock fell, he sold a thousand

shares at the market, until he had made short-sales of 6000 shares. Then came another period of 'watchful waiting,' and again the wait was of short duration. He 'covered his shorts' at about \$55, and cleaned up over \$200,000. Was this dishonest? I think not. He was not in the stock-gambling game—merely an interloper, but surely a good guesser. The really amusing thing about it all was that he afterward referred to the incident as, "my little flyer in mining."

AN ONLOOKER.

San Francisco, February 20.

Belgian Relief

The Editor:

Sir—Thank you for opening your editorial columns to Belgian Relief in your issue of February 17th. This brave and long-suffering little nation needs desperately all that we can give her, if she is to survive, and who among us can bear to contemplate her destruction? The last sentence of your able editorial may deter some from giving by suggesting that the German authorities may seize the supplies now in storage in the C. R. B. warehouses in Belgium. The chance of such an action I believe so remote as to be negligible.

The German authorities have given to the C. R. B. and to the Belgium Comité National a very clear and explicit guarantee not to touch any of the food-stuffs imported by the C. R. B. This guarantee the German authorities have always carefully and faithfully observed and it will continue in force whether the C. R. B. continues preponderantly American or not; and, even if the C. R. B. ceases to exist, I am convinced that the Belgians will get the last pound of food stored in the C. R. B. warehouses.

We have put our shoulders to the task of supporting this heroic little people. Let us not slacken in spirit but rather show our sympathy with them and our appreciation of our own Herbert Hoover by increasing our efforts a hundredfold.

E. COPPÉE THURSTON.

San Francisco, February 18.

Magnetite and Iron Sulphide

The Editor:

Sir—The interesting description in your issue of February 24, of the occurrence of magnetite associated with iron and copper sulphides in the ore of the Granby company's mine at Phoenix, B. C., calls to mind similar occurrences elsewhere. I first observed what I thought to be an unusual association of magnetite and sulphide minerals at a mine near Bayha, in Shasta county, California, and later saw a similar deposit in the Bright Diamond mine, a mile north of Ouray, in the San Juan region of Colorado, and I have seen it since in other places. I am under the impression that this association is more common than is generally supposed. C. R. Van Hise, in his treatise on metamorphism, page 845, says:

"Magnetite and pyrite also are often associated." He thinks the magnetite is formed from pyrite and siderite. This association of primary iron sulphide with iron oxide occurs in both copper and gold deposits.

W. H. STORMS.

Remedy for Powder Headache

The Editor:

Sir—A year or so ago while working in a drift where powder-gas was present in large quantity, I contracted a headache. Leaving the 'muck-pile,' I sat down and began using an ordinary menthol inhaler, and was gratified to find my headache 'on the run.' Since then I have suggested the use of menthol to several friends, each of whom claimed equally good results. I hope this may benefit others.

Ravalli, Montana, February 14.

JOHN A. ROOS.

Misfires

The Editor:

Sir—A discussion is a waste of valuable space unless it imparts useful information or brings forth pertinent opinions and facts from the reader, so I shall try to be brief.

In your issue of February 3, Mr. Brooks states: "The method I prefer in making primers is to punch a diagonal hole in the powder near the end of the cartridge, insert the cap, and bend the fuse across the end of the powder, and insert in the hole, cap-end first." The primer, Mr. Brooks goes on to state is the second stick from the collar of the hole. This procedure, as I understand it, causes the closed end of the detonator to point toward the collar of the hole.

By many tests of different sorts it has been proved that a detonator or cap delivers its hardest blow from the closed end. This end then should point in the direction that the detonation wave is to be propagated. The point of the cap should point into and not out of the drill-hole. I do not say that a charge will misfire if the cap is pointed out, but the effectiveness of the shot will be less than if the detonator is pointed toward the bulk of the charge.

Mr. Brooks is correct in saying: "I can hardly believe Mr. Weeks would suggest bulldozing in the face of a drift." I would suggest bulldozing in very few cases where a block-hole could be drilled. Bulldozing may 'get by' where a study of comparative costs is not made. In a recent conversation, Mr. B. L. Thane, manager of the Alaska Gold Mines Co. stated that he was endeavoring to do away with bulldozing in the chambers above the chutes on account of its high cost. His opinion was that a small pocket-drill would be developed for block-holing under such conditions.

To tamp or not to tamp? The no-tamping system is certainly the path of least resistance, actually and metaphorically. If Mr. Brooks is correct in his contention that tamping is useless, I wish to know it, for I loathe

unnecessary work, or, as my friend Professor Lawson would term it, "pernicious activity."

The question is rather a vital one, and its discussion I propose to leave to engineers who can produce first-hand evidence.

Berkeley, February 15.

W. S. WEEKS.

Slime-Agitation

The Editor:

Sir—In your article, published in your issue of January 20, on the mill of the Hedley Gold Mining Co. in reference to the propeller slime-agitator, you state you "know the power is crucial." This is quite true in some respects, I should say, but not altogether so. On account of the slime being heavy, the specific gravity of the ore being 3.3, considerable hesitation was caused in adopting an efficient method at the least expense, and the present propeller system appeared best adapted to the requirements of the plant. When least expense is considered, it should not dwindle to one item of power. Extraction, supervision, repairs, supplies, delays—anything that breaks the regularity and decreases the net profits—is an expense, as well as the power consumed. Anyone in charge of a mill realizes what it means to have a plant run with clock-like regularity, and that is what the Devereux propeller has done at Hedley—handled as high as 23 tons of slime per horse-power. I have delayed writing purposely, for I wished to give the latest results. Thus far, after running one year there has been no expense except grease—certainly an achievement that will rank with any machinery used in any department of a cyanide plant. As for the power consumed, I question seriously whether the horse-power consumed by the screw-propeller is greater than any of the standard machines in use when working under the same conditions.

At the Santa Gertrudis mill, at Pachuca, Mexico, according to an article by Hugh Rose, in August 1916, Bulletin A. I. M. E., a Pachuca tank 15 ft. diam. by 45 ft. high, probably holding 200 tons of water, or solution, requires 75 cu. ft. of air at 27 lb. pressure, which means about 11.2 hp. is needed to drive the compressor to furnish that amount of air, including compressor-loss, to agitate the charge of probably about 100 tons of dry slime in this one Pachuca tank. I have not access to the exact figures, but figuring from the dimensions given, and allowing for the usual cone at the base of a Pachuca tank, one can verify my figures as to the water-tonnage contents of the tank—as to tonnage of dry slime, good practice would not permit, usually, more than 100 tons in such a tank, or one horse-power for each 9 tons of slime.

Another example: The milling plant of the Compania de Minas La Blanca y Anexas, also at Pachuca, consists of eight Pachuca tanks 60 ft. high by 15 ft. diam. An average pulp-charge is 150 tons of dry slime in 180 tons of solution. One 150-hp. compressor is running every minute of the day to furnish air enough for agitation purposes for eight of these tanks, thereby putting into

agitation 8×180 tons, or a total of 1440 tons, or 9.6 tons of dry slime per horse-power.

At Hedley, with a 10-hp. motor, almost up to load, driving a 5 ft. diam. 4-bladed screw-propeller, revolving 76 r.p.m., in a tank of 34 ft. diam. by 18-ft. stave, including a 23° conical bottom, a charge of 191 tons of dry slime is agitated with 278 tons of solution, or 19.1 tons dry slime per horse-power. This is not the usual practice, but when the mill is crowded and delays have caused

rope slipped out of the operator's hand, while fastening, and twisted around the revolving propeller, there was danger of it breaking the shaft. This has now been obviated by a 2 by 12-in. fixed baffle-board across the tank two feet above the propeller as shown in Fig. 2.

Hedley, B. C. February 7.

ROSCOE WHEELER.

On Stamp-Milling

The Editor:

Sir—The discussion which has appeared from time to time in your columns relative to the merits of different mills has excited my liveliest interest, as it brings to my mind a controversy I had with an expert mill-man about two years ago at Cornucopia, Oregon. Any mill under adverse conditions cannot do its best work in full measure, and in order that a battery may give a first-hand account of itself the following conditions should obtain:

First: The top of the screen must not incline outward more than 5 to 10° from the perpendicular.

Second: With ores such as we have at Cornucopia, the feed must not be more than one inch; in fact, three-fourths of an inch under ordinary conditions is better still. By 'feed' I mean the ore lying upon the die, when the shoe attached to the lower end of the stamp drops upon it. The less feed given—provided the shoe does not work directly upon the die—the more crushing will be done.

Third: The principal product from our Cornucopia ores being in the form of a concentrate, the discharge should not exceed four inches, and in extreme cases, with such ore as we have in the Queen of the West mine, no discharge need be given. This low discharge of four inches or less causes damage to a screen occasionally because the ore in the battery presses against the screen and bulges it out, but this annoyance and cost of extra screens are more than compensated by the increase in crushing capacity and also extra good work done. The discharge is the distance between the top of the die and the lower edge of the screen, and as the water cannot discharge as rapidly as it flows into the battery, it requires some pressure to do so. Therefore, a four-inch discharge requires a five-inch head.

Fourth: Using a drop of 6 to 8 inches, we can get from 90 to 95 drops per minute. The drop is the distance between the top of the die and the bottom of the shoe at the time when the stamp has reached its greatest height, and the cam is leaving the tappet. Thus a drop of 6 to 8 in. under the foregoing conditions of 4-in. discharge, with one inch of feed on top of the die, would be equal to from 1 to 3 in. of air-drop, and this air-drop is the vital factor of battery efficiency. The stamps in their drop condense and carry the air with them, striking the pulp with a cushioned blow, which disturbs all the pulp in the battery, and it is this disturbance and cushioned blow that creates the splash, lashing the pulp against the screen with such force that all of it that is of the necessary fineness passes through the screen. This air-cushioned blow and splash also wash out and keep the

FIG. 1. AGITATION-TANK WITH HINGED BAFFLE-BOARD.

the slime-vats to be loaded more than the proper height, the propeller can be relied upon to do this work without any extra labor or cost involved whatever—it responds to the situation. Where crowding of the charge has buried the propeller under three feet of slime it has started without trouble.

Adjusting the revolutions per minute to the size of

FIG. 2. TANK WITH STATIONARY BAFFLE-BOARD.

the charge usually handled, to the weight of the material, to the style and dimensions of the vat is not a difficult problem, though experience has been a good teacher in my case. As its merits become known, I believe the use of it as an agitator will become more general, as well as the varied uses to which it may be put.

In the arrangement of baffle-boards to prevent surging, changes were made from time to time. First, a hinged baffle-board was tried as Fig. 1. While it worked well, it was not a positive check against carelessness, as it held the baffle in vertical position by a rope from the lower chord of the baffle to a cleat outside the tank. As this

battery flushed at every drop, thereby preventing sliming of the pulp, which is so much dreaded by mill-men whenever concentrating machines are depended upon to produce desirable results. The experienced battery-man has a keen eye for that splash; if none is present, the battery is not doing its duty. It is also worth while to remark that during the lifetime of the shoe or die, or both, the screens must be kept in proper position; the dies must be kept level and even—all of which plays a very important part in the successful operation of a stamp-mill.

In 1885 the mines of Cornucopia were discovered and in 1887 the late E. P. Torrey erected and operated the first 5-stamp mill in the district. It was supposed to be a most complete reduction works. We used no rock-breaker or ore-feeder, and with the battery and plates, four little Golden Gate concentrators and a section of burlap completed the plant. It was decided to make the first mill-run on low-grade ore packed from the Mayflower, Conundrum, O. R. & N., and other claims. There were seven bosses all equal in authority, and they were all tasting gold. After the mill ran one day, samples were taken—battery-sample \$5 per ton, tailing-sample \$3.75 per ton; everybody crestfallen. Then Mr. Torrey made a radical change about the battery, and then another day's run gave a battery-sample of \$5.10, tailing-sample \$1. Everybody jubilant. And while I believed that those stamps and Golden Gates were most wonderful machines to accomplish such reverse and gratifying results, yet, after all, behind that change was E. P. Torrey, indeed a master mill-man. "Oh! so easy." Hocus-pocus, cockalorum! Now you see it; now you don't see it. We all learned our first lesson in stamp-mill practice. And one may realize, after all, it's the man behind the gun that wins the battle.

HENRY MENTLE.

Huntington, Oregon, February 12.

Adaptability of Machinery

The Editor:

Sir—There are machines for almost every possible requirement in mining, and as a general proposition it is safe to say that it is not economy to attempt to adapt a machine intended for one kind of work to the performance of some other kind. I have had a practical demonstration that convinced me thoroughly of the truth of this statement. I was sinking a shaft, and for a hoisting-engine had a single-cylinder end-friction machine, probably intended for use on a dock, or almost anywhere else than at a mine. However, as money was scarce and this hoist, being second-hand, was inexpensive, I bought it. At one side it was equipped with a winch, keyed to a projection of the shaft. I needed a circular saw to cut cord-wood, and to make wedges, but had neither an extra engine nor power to spare. I thought the matter over and then hit on the brilliant idea of removing the winch, substituting fast and loose pulleys, and hooking my hoisting-engine to the saw-mill. This not only looked feasible, but was considered a fine scheme by all of us. To think

was to act. The necessary pulleys were bought and placed on the shaft and a complete little saw-mill was set up in front of the engine. When all was in readiness the new arrangement was tried, and it worked fine. We could not have asked more, unless it were a separate and suitable engine to run the saw. For several weeks we used this make-shift contrivance, and then the shaft of the hoisting-engine began to 'wobble,' indicating that the bearings were getting 'out of true.' This condition became worse, and after a few days, it got so bad that the hoisting-engine could not be depended upon, as a hoisting-machine, because it acted in a jerky and unsatisfactory manner. An examination showed that the bearing on one side of the machine was worn much more than that on the opposite side, and that the hoisting-reel with its shaft and bearings would have to go to a machine-shop, which it did. The result was a shut-down of a week and a direct expense of nearly \$70, but it was worth more than that to learn by practical demonstration that a hoisting-engine is not designed to run a saw-mill.

REUBEN YOST.

Jamestown, California, February 18.

Mine-Claim Tax v. Annual Labor

The Editor:

Sir—If the mining law is amended so that no actual discovery of "mineral-bearing rock in place" is necessary—a requirement of the present law—and a locator is enabled to hold his claims by annually paying a stipulated amount to the Government, would it not have a deterrent effect on the further development of the mineral resources of the West? As a natural result capitalists would acquire the greater part of the promising ground, particularly in newly-discovered districts, and hold it without development, merely paying the tax required by law, while leaving the actual development of the district to others. This they could afford to do, but it would put an end to the rapid exploitation of new territory that has been such an important feature of Western mining ever since the early days. I hope you will oppose vigorously any such change in the existing mining law.

OLD TIMER.

Manhattan, Nevada, February 10.

GRAPHITE PRODUCTION of Ceylon during 1915 amounted to 21,817 long tons, compared with 14,223 tons in 1914. Early in the past year the industry was quiet, but with the removal of the export embargo, prices advanced quickly and reached \$438 per ton for ordinary lump graphite.

SILVER is a better conductor of electricity than copper in the ratio of 1000 to 931, and both metals are better than aluminum for this purpose, though aluminum with twice the sectional area of copper is equally as good as copper as a conductor but is less desirable for other reasons.

PICTURE-WRITING NEAR EGYPTIAN MINES.

AN ANCIENT MINER DRILLING.

Modern Gold Mining in Ancient Egypt

By Ernest H. S. Sampson

The following remarks are supplementary to a short paper that I contributed to the Institution of Mining & Metallurgy in March 1906, entitled 'Gold Mining in Upper Egypt.' At that time considerable interest was evinced in this subject, and several companies had been floated to explore the deserts of Upper Egypt and the Sudan for ancient mines that might prove of value, and to undertake the development of new prospects. Among these companies were the Egyptian Mines Exploration Co. with its subsidiaries, the Central Egypt Exploration Co., the Fatira Exploring Co., and the Eridia Exploring Co. Of these the Central Egypt Exploration Co. was engaged in developing two prospects called respectively Fowakhir and Atallah. The former is situated on the northern Kenh-Kosseir road, a main caravan-route between the Nile and the Red Sea, 400 miles south of Cairo, and the latter is about 15 miles due north of Fowakhir.

Fowakhir was subsequently abandoned as unprofitable. Development work at Atallah, however, disclosed a rich vein of auriferous quartz, or rather a series of parallel veins for there were six in all. This mine was afterward taken over by John Taylor & Sons, and the last account I heard was that they were erecting a reduction plant on the property. The Fatira Exploring Co. investigated the old mines of Fatira and Semna—both considerably north of Atallah. The former proved to be low-grade, and, in view of a heavy influx of water, and lack of facilities at that time for unwatering the workings, it was abandoned.

Semna was, perhaps, the most promising of all the prospects in that district; a large and fairly rich vein being opened along an outcrop of about 1000 ft. As I was in charge of the operations there for two years I am able to give a fairly full account of this particular prop-

erty, as I propose to do a little later. Lastly, the Eridia Exploring Co. developed a mine of that name that had by far the longest outcrop of any of those mentioned. It, too, was low-grade, and in consideration of the excessive charges for freight and supplies at that time, coupled with the great difficulty in transporting heavy machinery across the desert, this also was abandoned—temporarily, at all events.

The parent company proposed to construct a light railway, at a cost of \$2500 per mile, from the Nile to this group of mines, all of which are within 60 miles of the river. The total length of railroad required to link the respective mines was 100 miles. This, with an equipment of three locomotives and a hundred wagons, involved an expenditure of approximately \$300,000. The directors unfortunately were unable to convince the shareholders and others that the prospects were sufficiently attractive to warrant this further outlay before any returns would be forthcoming. This led to the abandonment of the scheme, and the closing-down of the Atallah, Eridia, and Semna mines at a time when two of them were looking promising.

In the course of a prospecting expedition undertaken by a colleague and myself in the fall of 1903 we discovered several other ancient mining-sites apparently as meritorious as any of the before-mentioned properties, but so far as I am aware these have remained untouched to this day.

On account of the scarcity of water, lack of transportation, and the presence of warlike tribes of Arabs, such as the Maazi, who are hostile to strangers, Egypt is no place for the individual prospector; and the Government, recognizing this, has wisely made laws that preclude any possibility of individual enterprise of this nature. In

the first place, it is necessary to obtain a large concession from the Government, legally called a 'prospecting area,' and to do so a considerable sum of money must be deposited with the Government as evidence of good faith. At a later date, if it is desired to work any particular mine seriously, a mining lease must be taken out and a yearly rental paid for the required number of acres. Also a royalty on the output is demanded by the Government. And here I may say that any relics, or *antika*, as they are called in Egypt, to be found during excavation, or otherwise, must be handed over to the authorities, who reserve the right to the possession of them.

The only present means of transport from the Nile or the Red Sea to the mines is by camel. The maximum load a strong camel will carry is about 500 lb., but the best contract that we were able to obtain from the Sheiks, who are the great stock and land owners of the country, was for an average load of 300 lb., for which the charge was \$2.50. For this sum, however, they would carry back with them to the Nile a similar load free of additional cost. On the arrival of a caravan, no matter of how many camels, it was necessary to weigh the total load carried, and dividing this amount by 300, give the drivers a check for so many camels. This they would hand to the Sheik, their master, on their return, who in turn handed it to the mining company's agent at Keneh, for payment. Much haggling often ensued, as the Sheik would frequently insist that he had sent out, say 30 camels, and yet had only been given a check for perhaps 25 loads. This, of course, was all in the day's work, so to speak, for the Eastern mind is incapable of making a straight business transaction without bargaining or subterfuge, and for this due allowance had to be made.

It was estimated that by the construction of a light mine-railway of, say, 24-in. gauge, with steel rails, 16 lb. per yard, and steel ties, the cost of development at the mines would be reduced by about 30% at least. I think, however, that the figure quoted for construction, namely, \$2500 per mile, was altogether too high. Unskilled labor cost at that time from 5 to 6 *piastres* (25 to 30 cents) per day, the men finding their own food, and, as a considerable portion of the track could have been laid with little or no preparation of the road-bed, and as there was an almost entire absence of tunneling, or even rock-cuts, I am of opinion that a much lower figure would have sufficed.

Atallah is situated 45 miles due east of Keneh, a large native village on the Nile, and lies at an elevation of 1600 ft. above sea-level. The auriferous veins traverse a country of coarse-grained gray granite, and strike north-east-southwest, having a dip of from 40 to 60°. At the south-western end of the outcrop the main vein passes into a formation of talcose schist and is intersected by a dike of intrusive rock. At the north-eastern end it terminates abruptly on the surface, the gray granite giving place to red felsite. A characteristic of the main vein is a repeated step-faulting that occurs below a depth of 250 ft. measured on the dip, the missing portion of the vein being found in the foot-wall. The gold-bearing

quartz varies in color from white through various shades of blue, to almost black, in places. In addition to the precious metals it contains small quantities of lead, copper, iron, arsenic, and traces of antimony. A general sample of 75 lb. taken from all parts of the mine where the assays showed more than \$10 in gold per ton, was assayed in London and gave a value of \$125 in gold and 2.5 oz. of silver per long ton. Assays ranged from a few dollars up to about \$200 per ton during the development period. The ancient workings on this vein were deep and extensive, but the maximum depth to which they were accessible was only about 200 ft. measured on the dip.

SEMNA MINE. The name 'Semna,' meaning in Arabic 'grease,' was probably applied to this mine by the Arabs on account of the greasy appearance of the schistose rocks that abound in the neighborhood.

As at Atallah, the main vein traverses gray granite, and, indeed, I may here remark, that this was invariably the case with all the good-looking ancient diggings that I visited in the course of our expedition. Quartz veins in the red granite, no matter how persistent, or how promising they appeared, were found to be barren of precious metal.

The main vein strikes almost due east-west and dips south at 60°. It consists of white quartz much stained near the surface with iron oxide, and carrying some chalcopyrite. It varies in width from 2 to 20 ft., having an outcrop about 1000 ft. long. It was opened up by three shafts—a vertical one at each end of the outcrop on the hanging-wall side of the vein, and an inclined shaft about midway between these sunk on the foot-wall side of the vein and about 20 ft. from it. Cross-cuts at intervals of 50 and 100 ft. in depth were driven from this to intersect the vein, which down to a depth of 160 ft. was found to maintain a regular dip, all the cross-cuts reaching the vein at practically the same distance from the shaft. Ancient workings were found to extend to a depth of over 100 ft. and little quartz was found in place until these had been passed.

The vertical shaft (No. 1) at the east end of the outcrop, intersected the vein at a depth of 75 ft. from the surface. It was found to be 12 in. wide with a gold value of \$45 per ton. A drift east showed the vein to be gradually widening, until at 65 ft. from the shaft it was 15 ft. thick. For a length of 70 ft. the vein averaged 60 in. with an assay-value of \$60 per ton.

The other vertical shaft (No. 3) was 770 ft. west of No. 1 and cut the vein at 80 ft. from the surface, but was continued to a depth of 123 ft. before driving was commenced, that being at the same level as the drift in No. 1. The east drift for 47 ft. showed a vein 30 in. wide with a gold-value of \$8 per ton; the westerly drift for 33 ft. showing an average width of 22 in. assaying \$7 per ton.

The inclined shaft (No. 2), subsequently used as a main hoisting shaft, gave considerable trouble for the first 50 ft. on account of heavy falls of rock from the hanging wall, which was weak. It was necessary, however, to have a shaft at this point, as, on account of the

ground rising steeply above the outcrop on the hanging-wall side of the vein, it was not feasible to sink a vertical shaft on that side. At a depth of 50 ft. the first cross-cut was driven southward to the vein, which it cut at a distance of 24 ft. Here the vein was 48 in. wide, assaying \$5 per ton. Drifts east and west along the vein soon

development work was done, the contour of the ground lending itself to the driving of adit-levels or cross-cuts. Although the vein was well defined and persistent no very high-grade ore was obtained during development, the best assay reported being \$72 in gold, and the average perhaps \$15. The width varied from a few inches up to four feet.

The following table shows the rates of pay for the different classes of native labor in and around the mines in Egypt at the time of which I write, and probably still obtaining there:

Unskilled labor (boys)	15 to 20 cents per day
Unskilled labor (men)	30 cents per shift
Hammer men	40 cents per shift
Carpenters	60 to 70 cents per day
Blacksmiths	60 to 70 cents per day
Foremen	75 cents per shift
Cooks and servants	*\$20 to \$30 per month

*According to whether speaking English fluently or not at all.

In every instance, with the exception of cooks and

A RESTING-PLACE ON THE DESERT.

reached old workings. Driving eastward for a distance of 80 ft. we found nine pillars, left by the ancient miners. These had an average width of 36 in. of ore assaying \$40 in gold per ton. Westward at 23 ft. from the shaft, the vein was 55 in. wide, and assayed \$18 per ton.

At 150 ft. from the surface a second cross-cut was driven south. This also cut the vein at a distance of 24

GRANITE BASINS OF ANCIENT MILLS.

OPEN WORKINGS OF AN OLD MINE.

ft., the quartz being 24 in. wide and assaying \$10 in gold per ton. Drifts east and west were started at the same relative level as the drifts in No. 1 and 2. At the time the property was closed down these had been driven almost the entire length of the outcrop, that is to say 1000 ft., and on the west side of No. 2 shaft a winze had been sunk to a further depth of 100 ft. or more.

ERIDIA MINE. The outcrop at this place was traceable for 1500 ft., the vein striking north and south. Its dip was 80° west and regular throughout. Considerable

servants, the men provide their own food. Carpenters usually supply their own tools, preferring to use the kind to which they have been accustomed rather than the product of Western civilization.

The cost of living for white men is high, from \$100 to \$125 per month being a fair average for two men living together, exclusive of any allowance for mineral waters, alcoholic liquors, or tobacco. This is offset to some extent by the few requirements in the matter of clothing and the lack of spending facilities in the desert.

Of the ancient mining-sites mentioned above, on which no development work has been done, the largest was at a place called Abou Had, which lies almost directly south of Eridia, half a day's journey on camel-back. Here, among rugged hills, we found a large vein of white quartz striking northwest-southeast, intersecting gray granite. This vein had been worked by the ancients to a considerable extent, and near-by were ruins of old houses, in which were the remains of stone crushing-mills, and the usual accompaniments of these primitive mining camps. Samples taken from pillars of ore left by the ancients

usually showed a good prospect of free gold on panning.

Other places worthy of note that would, I think, repay investigation were the old mining-sites of El Rebshi and Um Hat. At the former there are many hundreds of pits each about 10 ft. deep sunk in the sand of the 'wady' or valley and often connected by low tunnels. These, so our guide informed us, had been sunk by the ancients to work an auriferous vein hidden beneath the sand. I think it more probable that they were dug for the purpose of obtaining placer gold, brought down from the neighboring mountains at a period in the history of Egypt when rain-storms were more frequent than at the present day.

At Um Hat we uncovered a small flat vein of copper-glance rich in silver. It was a contact-vein formed at the junction of red granite and talcose schist. This was the only instance of a deposit carrying either gold or silver that I ever observed in the red granite during my three years in the Arabian desert. Within a radius of several miles of this deposit the rocks were frequently seen to be stained a vivid green by copper carbonate. During the short time at our disposal we were able to make only a cursory examination of the locality, and, having no explosives with us, could do little more than clean the drifted sand from one or two of the old workings. In every instance the ancient miners had removed all the ore, I believe, however, that this district would repay the time and money spent in intelligent investigation, as there is every indication of it having been a prosperous copper camp in the past.

To sum up, this particular part of the eastern desert of Upper Egypt lying midway between the Nile and the Red Sea is well worthy of the description accorded to it by the ancient writer Diodorus, who says: "In the confines of Egypt there is a place full of rich gold mines out of which with much pains, and labor of many hands, gold is dug. There are, I believe, few places in the world so easy of access that exhibit such attractive prospects for the use of capital."

HOARDING OF GOLD. What becomes of the gold that disappears from circulation? There is at least one cause for the disappearance of gold that is of much greater importance than is generally supposed. This is hoarding of the metal in the form of coins. There are a great many people who fear to trust their money in banks or in the hands of any other person, and who shun every form of investment. They prefer the loss of the usual interest to the possible loss of the capital, consequently these people hoard their money, usually hiding it in out-of-the-way places. Some keep their gold in tea-pots, tin-cans, or other vessels; others bury it. This practice is more common abroad than in the United States, but is carried on to an astonishing degree almost everywhere. In Egypt, some years ago, a man died leaving \$400,000 in gold, all of which was buried in his cellar. Another closed a deal for a piece of real estate for \$125,000. Half an hour after the deed had been signed this man ap-

peared with a string of burros carrying the coin which had been buried in his garden. Frequently after a fire the owner of the destroyed property begins placer-mining operations in the ashes in search of the coin he had hidden, but which he had been unable to rescue from the flames. In Spanish-speaking countries, silver as well as gold is commonly buried, particularly in those countries where the government is unstable.

Sharpening Drills for Seamy Ground

Sometimes a miner encounters seamy or broken ground, especially when it is composed of hard shattered rock says *The Coal Age*. The ordinary drill, sharpened as shown in Fig. 2, then does not give good results, for the

FIG. 1. A DRILL-BIT AS IT SHOULD BE SHARPENED.

FIG. 2. THE OLD WAY OF SHARPENING A BIT.

edge is frequently driven into a crack so that it is practically impossible to loosen or remove the drill.

This difficulty may be overcome by sharpening the drill as shown in Fig. 1, where it will be seen that the corners have been turned back so that the cutting edge assumes a curved outline. Such a drill-point as this will ride over ordinary cracks, and thus prevent sticking.

THE FIRST ROCK-BREAKER on the market in the West was the invention of Eli Whitney Blake, of New Haven, Connecticut. It was designed originally to break trap-rock for macadam. In 1861 it was introduced in the gold-mills of California, the first one being placed in the Benton mill, at what is now Bagby, on the Mariposa grant, the property of the Mariposa Mining & Commercial Company.

A HYDRAULIC-ELEVATOR will lift gravel to a height equal to about one-fifth the height of the pressure-column of water employed to operate it.

Western American Metallurgy

By A Visitor From Abroad

[The following review of metallurgical practice in the West consists of the notes made by a mining engineer, recently a visitor to the United States from a foreign country.—Editor.]

POWER. The outstanding feature noticed in this respect was the almost universal use of electricity as the motive power, and, wherever possible or feasible, the use of separate motors to operate individual machines or small groups of similar machines. Rarely I observed that, where it was for some reason not considered advisable to operate individual machines by separate motors, the most usual arrangement of the plant was that one large motor was provided for each complete section or unit of a plant, thus permitting any one section or unit of such a plant to be out of operation without interfering with the continuous working of other sections or units.

In passing, I may mention that electric mine hoisting-plants seem to be rapidly advancing in favor and to be replacing steam-driven hoists. At the Butte mines of the Anaconda company, in order to equalize the line load, it has been found to be more economical to operate hoists with compressed air under constant pressure on account of the cheaper conversion of the previously installed steam hoisting-plants. The Anaconda company makes use of hydrostatic receivers to maintain such constant air-pressure, and, it is said, with great resultant economy. On the other hand, smaller companies in the neighborhood are rapidly adopting electrically operated hoisting-plants.

The latest phase of electric hoisting is to be found in the Inspiration Copper Co.'s plant, where all the hoisting from two shafts is done by means of two electrically operated hoists working in tandem automatically. The record tonnage hoisted per 24 hours is about 19,000 tons. Also for raising and lowering men and supplies down to the 750-ft. level, an automatic elevator of the Otis type is in operation. The power-plant containing these hoists also houses the low-pressure air-compressors (100 lb. per sq. in.) for machine-drills and the high-pressure air-compressors (800 lb. per sq. in.) for underground mine-haulage by compressed air-driven locomotives. In this power-station is contained probably 7000 hp., yet the total attendance required is only two men per shift, one electrician and one mechanic.

Referring to general practice in driving flotation-machines, I noticed three methods of driving machines of the mechanical-agitation type. The Minerals Separation type of machines in the Anaconda plant are driven direct from motors coupled to the main driving-shaft, and thence through steel-bevel gearing to the vertical agitator-spindles, one motor being provided for each machine. In other plants visited the main driving-shafts

were belt-driven from individual motors. In all cases bevel-gearing has replaced the former practice of quarter-turn belt-transmission between the main line-shaft and vertical spindles on machines of the Minerals Separation type. In the Janney type of machines the practice is to provide an individual vertical motor direct-connected to each spindle. The method usually adopted for driving rolls and Chilean mills was by belts from individual motors or from line-shafts. Tube-mills and conical mills are invariably driven by separate motors by means of gearing, and in the latest plants this gearing was of the double herring-bone or Wuest type.

MILL-HEATING. Steam-heating was the practice generally noticed—either by high or low-pressure steam. The most satisfactory method I saw was at the Timber Butte mill, where high-pressure steam is used to heat air that is distributed throughout the mill by means of fans. At the time of my visit the outside temperature was quite cold, but the mill throughout was maintained at an even and pleasant temperature, with the exception of the coarse-crushing plant, where no heating was provided.

LIGHTING. Electric lighting is universally adopted, single lights being provided for individual machines and large lights over an aggregate of machines. All mills are provided with the largest possible number of side windows, and in many of the larger mills roof-lighting is also employed to provide efficient illumination during the day-time over all machines.

BUILDING CONSTRUCTION. Steel framing covered with galvanized corrugated iron is almost universally adopted. In the latest mills I noticed that reinforced concrete was being largely used for the lower floors or sub-floors. Notable examples of this can be seen in the Timber Butte mill and the Miami mill.

FIRE-PROTECTION. Great attention is paid to this item. Where it is not possible to provide a large high-pressure reservoir, special automatic fire-pumps are in general use. The fire-protection service at the Timber Butte mill may be taken as illustrating the best modern practice.

MILL-SITES. As the principles underlying the selection of a suitable mill-site is one of considerable interest to my company, particular attention was paid by me to this question. I obtained the views of those in charge of the various mills visited on this subject.

The practically unanimous opinion was that

1. Wherever practicable the mill should be built as

close as possible to the point where ore is delivered from the mine.

2. The importance of selecting the mill-site high upon a hillside, so as not only to provide ample head-room for the impounding of mill-tailing, but also to provide ample additional elevation for future extensions of metallurgical plant or the subsequent need for future re-treatment of mill-products.

In many instances the older mills are now suffering inconvenience and additional expense owing to the failure originally to provide or to foresee fully the inevitable extra elevation for additional plant that sooner or later arose, due to improved metallurgical processes, or to accommodate a larger tonnage of tailing than was at first estimated.

It was also the general opinion that wherever possible it was better to select a site closer to a mine, and pump water therefrom if no other supply was available, than to allow the proximity of a water-supply to govern the choice of a mill-site.

Gravity sites, where possible, are universal, and in cases where insufficient slope is available, the deficiency of elevation is made up by extensive use of inclined belt-conveyors in the arrangement and placing of the coarse-crushing plant, thus allowing the rest of the mill to take full advantage of a gravity flow. In the case of the selection of the present site of one of the larger modern mills, we were informed that after the development of a sufficient tonnage of ore in the mine had been completed and the required milling plant designed, the selection of the site was decided entirely from a milling standpoint. The position of the main shaft was then selected to suit the mill, and it was placed so as to deliver ore immediately to the crushing plant.

In another instance, where the shaft was only some 300 ft. distant from the mill, a new shaft was being sunk to deliver ore more conveniently direct to the mill-bins. In other instances, where mines were situated more or less in the centre of a town and no possible immediately adjacent mill-site was available, there was no alternative to erecting a mill away from the mine; and in such cases the plants have been placed on a height, so as to provide ample elevation and tailing space for all future requirements so far as could be foreseen.

TRANSPORT OF ORE. Where local conditions have not permitted the placing of the mill immediately adjacent to the mine, standard-gauge railway-cars of 50 to 60-ton capacity are used. Ample provision is made for ore-storage, both at the mine and the mill, thus overcoming any delay due to trouble on the railway.

PRIMARY ROCK-BREAKING. These plants are situated either

(a) Immediately adjacent to the main shaft and often forming part of the head-frame structure.

(b) At the mill.

The primary rock-breaking, whether done at the mine or mill, is performed in two stages, the final product being reduced to suitable size for feeding to the grinding-plant ore-bins. The crushing machines comprise the fol-

lowing combinations, with intermediate screening of fine material:

1. Primary and secondary jaw-breakers.

2. Gyratory primary crushers and secondary jaw-breakers.

3. Gyratory primary crushers and roughing-rolls as secondary breakers.

4. Gyratory primary crushers and Symons disc-crushers for secondary breaking.

The combinations vary according to individual preference and the physical nature of the rock to be crushed. No. 4 probably represents the latest practice, but it is not to be advocated for soft or clayey ores. Neither would any combination including rolls be satisfactory for ores of this type. The final rock-crusher product is usually broken to pass a 2½-in. opening, and at this size is delivered to the mill ore-bins.

Where No. 3 and 4 are applicable, it is found that a larger percentage of undersize is produced than with either No. 1 or 2.

All primary rock-crushing plants are provided with grizzlies to screen out the undersize before the primary breakers. In many instances secondary grizzlies or revolving screens are used between the primary and secondary crushers to screen out material already sufficiently crushed. Screens or grizzlies are not used after secondary crushing. The grizzly oversize is carried to the primary crusher in pan-conveyors, and belt-conveyors are employed for the crushed material and the undersize. Very little ore-sorting was noticed; probably the cost of labor makes ore-sorting unprofitable.

CRUSHED-ORE STORAGE. In plants that are placed at some distance from the mine, necessitating rail transportation of crushed ore, ample capacity of crushed-ore storage-bins is provided at both crushing plant and mill. Where the crushing plant is placed at or close to the mill, proportionately larger crushed-ore storage-bins are provided at the mill.

It is interesting to note that the recently erected plant at the Alaska Gold Mines, whose plant is situated on Gastineau Channel, Alaska, includes large-capacity underground storage-bins situated between the rock-crushing plant and the mill proper. The transportation of ore between the underground bins and the mill ore-bins is effected by means of belt-conveyors on a 1% down-grade, which slope is almost sufficient to make the belt-conveyor self-acting. The Alaska Gold Mines plant has a capacity of 8000 to 10,000 tons per day and is considered to embody the most modern practice.

PRIMARY GRINDING. Ball-mills continue to come into favor. The straight cylindrical type is now being favorably considered as against conical mills. In cases where the ore is clean and free from adhering and sticky material, rolls have been largely used, and in many plants are considered to be the most efficient primary-grinding machines down to about 8 to 12-mesh. The trend of recent practice inclines to the use of ball-mills of large capacity, operating them in direct closed circuit with a classifier, or operating two such mills in series multiple

circuit with classifiers, that is to say, each ball-mill receives initial feed and the oversize from the classifier produced in mill *A* is delivered to mill *B* for further grinding and the reverse, thus establishing a closed circuit. This is the practice followed at Inspiration.

It is noted that in the large milling plants of the Utah Copper Co. rolls were formerly used exclusively for primary grinding. At the time of my visit experiments were being conducted on two sections of the Arthur mill with a view to comparing the relative efficiency of the Marcy mills in closed circuit with classifiers, producing a finished product, as against the practice of primary grinding in rolls and secondary grinding in Chilean mills. The general impression prevailing at the time was favorable to ball-mill grinding. In regard to that, the general opinion seems to be that for ball-mills used as preliminary grinders, when using balls of 5-inch diameter, the feed need only be crushed to pass a 3-in. ring. Finer feed on the large Marcy mills has not increased the output; on the contrary, reduced output has in more than one case been the result. It is advantageous apparently that the ball-mill feed should contain a certain proportion of coarser ore.

SECONDARY GRINDING. For grinding down to about 30-mesh, high-speed Chilean mills are largely in evidence, but competitive tests were being made in several plants to prove the efficiency of cylindrical ball-mills in this field and opinion seems about fairly evenly divided as to the relative merits of these machines, with, if anything a balance in favor of cylindrical mills. Anaconda formerly used Chilean mills for secondary grinding, but since the introduction of the flotation process into that plant the management has entirely discarded Chilean mills in favor of conical mills. It seems more than probable that in new plants cylindrical or conical mills will entirely supersede Chilean mills for secondary grinding, and so far as one can judge from the various opinions expressed, there is little to choose between the relative merits of modern-type short cylindrical mills as against conical mills.

RE-GRINDING. For re-grinding material to pass a 65-mesh screen, or finer, both conical and cylindrical mills are almost universally used. Competitive tests were in progress at several mills, both between cylindrical and conical mills, and also between the efficiency of pebble-grinding in silix-lined mills as against metal lining using steel, manganoid, or other types of balls. The preponderance of evidence seems to incline to the use of steel lining and metallic balls of a maximum diameter of three inches on account of increased output and lower net consumption of grinding media. The present scarcity of pebbles is also a consideration. As in the case of secondary grinding, opinion seems fairly evenly balanced between the relative merits of the two types of mills. In passing, it is of interest to note that the Anaconda re-grinding plant was equipped with 10-ft. diam. conical mills with silix linings, but owing to excessive pebble consumption (14 lb. per ton ground) caused chiefly by breakage due to the large size of the mills, the internal diameter has been reduced to 7 ft. 6 in. by wood lagging faced with

the Cascade type of steel liners; and chrome-steel and manganoid balls are now in use.

During my journey I had little opportunity of visiting all-sliming grinding plants, but I believe that the longer type of cylindrical mill is still pre-eminent in this field. In using balls for re-grinding, these should not exceed three inches diameter, and in many cases preference is given to a maximum diameter of $2\frac{1}{2}$ or even 2 in., when handling minus $\frac{1}{4}$ -in. feed, and to operate the mills in closed circuit with classifiers, and a heavy return-oversize feed, even up to 300%, and particular attention is paid to pulp consistence. It should be noted that all the foregoing remarks on grinding have more particular reference to recent copper-milling practice as distinct from purely gold-milling practice.

ORE-CONVEYING. For conveying coarse ore inside a mill steel pan-conveyors are almost uniformly used. In the plants I visited fine ore was without exception conveyed on rubber belts, and during the trip I have seen many miles of such equipment, some of the belts being of considerable length. Belt-trippers were in universal use. Hand-trucking inside mills was not observed in any one instance. Fine ore is elevated by belt and bucket-elevators, and modern practice has increased the speed of bucket-elevators with a general increase in the diameter of the head-pully. Pulp is elevated by bucket-elevators, centrifugal pumps of various types (Cripple Creek practice), air-lifts, and diaphragm-pumps. Bucket-elevators represent the best practice in concentrating mills and diaphragm-pumps are usually employed in cyanide mills in conjunction with counter-current decantation where it is necessary to regulate accurately the rate of pulp-transference. For the general elevation of pulps, bucket-elevators seem to hold the field, air-lifts being usually classed as unreliable and likely to cause trouble in operation.

CLASSIFICATION. Dorr and Akins machines are mostly used. Where accurate classification of slime is required, the Dorr machine is preferred, that is, where it is aimed to produce a slime free from oversize. On the other hand, where sand is required free from slime, the Akins machine holds the field. This machine is also generally used for dewatering coarse tailing. In classification for table-feed the Richards-Janney and Richards hindered-settling and the Deister cone-baffle classifiers are in use. At Anaconda a special classifier has been developed to suit local requirements, namely, to deslime roughing-table feed, but this was developed prior to the perfection of the mechanical classifier. In some mills double-cone classifiers are still in use, but these seem to be rapidly going out of fashion.

THICKENING AND DEWATERING. For this class of work the Dorr thickener is generally employed.

FILTERING. The Oliver filter (and the Portland form of the same filter) is preferred when only dewatering is aimed at, but when, as in cyanide-plants, it is necessary to displace gold-bearing solution contained in the filter-cake in order to obtain maximum recovery, Butters and Merrill filters are in use, the former being stated to be

preferable on account of lower initial cost and greater flexibility of operation. For dewatering flotation-froth, the Oliver (or Portland) filter is in most common use and in such plants as I visited, where other types of filters were in operation, those in charge were as a general rule about to replace these with Oliver filters or would like to do so.

THICKENING AND DEWATERING FLOTATION-FROTH. As stated above, Dorr thickeners and Oliver filters represent the latest practice. From 25 to 40 sq. ft. of settling-area in the thickening-tanks are about the usual limits allowed for dewatering one dry ton of flotation-concentrate per day. To dewater to a consistence of 60% solid in the underflow product, tanks of a minimum depth of 12 ft. are used, and this consistence—about 60% solid—seems to be most favored by those operating continuous filters. Such a consistence of concentrate is enough to hold the coarser particles in suspension without excessive agitation in the filter-tank. Under these conditions, continuous revolving filters have an approximate average capacity, when handling mixed table and flotation-concentrates, of one dry ton of concentrate per four square feet of filter-area per 24 hours. In the case of flotation-concentrate alone eight square feet is a normal allowance, and this figure varies considerably with the fineness of the concentrate; where heavier oils are used as flotation reagents, it may run as high as 12 ft. for all *minus* 200-mesh material at 60% solid consistence. The general vacuum maintained when handling mixed concentrates seems to be within 6 and 8 in. of mercury and the cake produced varies from $\frac{3}{4}$ to $1\frac{1}{4}$ in. thick at normal speeds. The moisture in the cake discharged is generally about 13%, but in more favorable cases, where coarse concentrate predominates, as low as 9% of moisture is in some plants being maintained. On the other hand, in plants handling solely flotation-concentrate of a fine nature, where heavy oil is used as one of the reagents, the vacuum maintained is as high as 25 in. and a cake only $\frac{3}{4}$ in. thick is being produced, containing 18 to 22% of moisture. The approximate consumption of power on an Oliver filter, 12 ft. diam. by 11 ft. 6 in. long, averaged in the various plants about 30 hp. when Roots exhausters were used to produce the vacuum (in the case of low vacuums). In the case of a high vacuum being necessary, dry-vacuum pumps are employed. The scrapers for removing the cake in the 11 ft. 6 in. filters have to be supported in the centre on account of the weight of concentrate they remove.

FLOTATION PRACTICE. The Minerals Separation type of machine seems to be giving generally the best results and operating with the minimum amount of attention. After having had an opportunity of seeing the Janney, Callow, and Gahl machines in operation at different mills, it would appear to me that on ores that are floated with difficulty the mechanical type of machine is to be preferred. There has been steady progress in the design of the M. S. type of machine—the original form using the quarter-turn belt-drive is seldom found; recent machines having adopted a bevel-gear drive. To equalize

the thrust in the geared machines the general practice is to use left and right-handed impellers in adjacent agitation-cells, at the same time ball-bearing thrust-washers are likewise in use between the driving-gear and the bearing.

The most recent construction employs a concentric coupling for each two boxes, so that, if repairs are needed, only the length of shafting over two boxes need be removed; at the same time these couplings compensate for any shrinkage or expansion of the wood-work of the machines without putting undue strains on the moving parts. The gear-boxes are provided with removable bottoms, and the vertical spindle-bushings are provided with stuffing-glands to prevent leakage of lubricating grease from the gear-boxes. Cut-gears are used made either of steel or phosphor-bronze. The latter are to be preferred; they give better mechanical efficiency and smoother running, although adding considerably to the first cost of the machine.

The latest type of drive for the M. S. machine is to have the motor direct-connected through a flexible coupling to the main shaft. This gives the most efficient drive, but it does not allow of any change of speed, should such be necessary, and it also requires far heavier construction to support the motor when it has to be built onto the machine.

Regarding the respective merits of the mechanical-agitator type of machine and the pneumatic type, it has always been claimed that the pneumatic type was more economical in power consumption. This contention was not confirmed by the engineers in charge of the competitive tests at several of the mills I visited, where after the most detailed investigation the M. S. type of machine was finally adopted.

The general view held by those I have consulted who are using, or who are familiar with the operation of pneumatic machines, is that this system fails to float coarse sulphide particles, say, plus 65-mesh and coarser. This opinion is held by some to be erroneous and the Inspiration and Miami, where the grinding is through a 48-mesh screen, are quoted. At Inspiration the flotation-plant is followed by concentrating-tables for the coarser sand and at Miami concentrating-tables precede the flotation-cells, and only the finer sand and slime are floated. The Inspiration tests on the ordinary pneumatic cell apparently showed that the pulp passed too rapidly through the machine, and to overcome this defect a special machine was designed, which, while following the general pneumatic principle, has provided means to overcome this objection, namely, by introducing regularly adjustable baffles, and decreasing the inclination of the air-blankets forming the bottom of the machine to $\frac{1}{2}$ in. per foot. The total length of the roughing-machines introduced at Inspiration is 51 ft., divided into 16 compartments, each 3 ft. long.

According to the advocates of the pneumatic machine, successful flotation depends not so much on the amount of agitation, as in the selection of the most suitable oil mixture, and its proper emulsification, the reagents

used, the choice between acid, neutral, or alkaline circuits, and temperature.

A great deal of attention is now being paid to a new phase of flotation, generally termed 'film-flotation,' that is, the coating of oxidized ore with a film of sulphide, produced by added reagents, such a film giving the oxidized minerals the flotation properties of the sulphides. I learn that one group is gradually acquiring all the existing patents covering this phase of flotation that are for sale, and are now watching developments until their process is perfected, when they will proceed against infringers.

These processes, I understand, apply particularly to the use of sulphuretted hydrogen, alkaline sulphides and poly-sulphides, together with the use of an alkaline circuit.

In my opinion the Janney machine does not appear to show any advance over the Minerals Separation machine—rather the reverse—as the higher speed of the former requires approximately 10% more power in units of equal capacity; the average peripheral of the Janney impeller being about 2000 ft. per minute, as against an average of, say, 1400 ft. per minute in Minerals Separation practice. For instance, in 600-ton capacity machines, the Janney was consuming 9.1 hp. per spindle as against 8.1 hp. per spindle for Minerals Separation machines. The latest development of the Janney machine is the provision of an air-blanket in the last cells of the machines, in order to reduce the copper content of the final tailing and produce a low-grade middling for re-treatment.

In treating large tonnages by flotation, a considerable diversity of opinion exists as to whether it is more profitable to use the same number of cells in series or in multiples. For instance, a plant consisting of one machine having 16 agitation-boxes, or two machines each having eight agitation-boxes, and each handling one-half of the feed. In the first instance, to draw off a clean concentrate from the first four or six boxes and re-treat the middling from the remaining boxes either by returning it to the original feed or re-treating in a separate machine. In the second instance, to draw off a clean concentrate from the first two boxes of each 8-box machine, and re-treat or return the remaining froths.

In this connection the latest practice at the Timber Butte mill is of great interest. At this mill the flotation-plant consists of three machines:

- (1) A primary roughing-machine of 19 agitation-boxes in series.
- (2) A middling-machine of 5 boxes, also in series.
- (3) A re-cleaning machine of 8 boxes, in two multiples of four boxes in each series.

In spite of the success obtained by this arrangement, it is now intended to erect a second flotation-plant in this mill, in which the roughing-machine will consist of 20 boxes operating in two multiples of 10 boxes each.

FLOTATION OILS AND REAGENTS. The general tendency is to use the cheapest and crudest types of oil, and such as are obtainable in the greatest quantity. One of the initial difficulties of large flotation-plants is the pro-

vision of an uninterrupted supply of the particular oil required; and this question of supply is taken into more serious account than the actual cost of the oil. Admixtures of wood-creosotes and coal-tar (and acid) are the most common compositions used on the Minerals Separation machines. Pine-oils and reconstructed oils are generally used on the Janney machines, and these types of oil at the present time are costing more than the wood-creosote mixtures, and as far as I am able to judge, the amounts used per ton treated are about the same. The main variation in the creosote and tar mixture lies in

MAP OF ARIZONA, SHOWING SOME OF THE LOCALITIES MENTIONED.

the amount of sulphuric acid used. Naturally, the use of acid on ores containing a limestone gangue is impossible. Sulphuric acid seems to be beneficial in obtaining a higher-grade concentrate from ores that contain alumina as a kaolin slime, probably due to the production of aluminum sulphate, which acts as a flocculant.

I heard a great deal about heavy top-sulphur oils, reconstructed pine-oils with resin added, and an artificial poly-sulphide of lime termed 'calura' (sodium hydrate, sulphur, and lime), also sodium sulphide, and other reagents, but, so far as results show, the wood-creosote and tar (and acid) mixture is more than holding its own.

IN HANCOCK COUNTY, MAINE, the Holman Molybdenite company is developing a large deposit of molybdenite, which is expected to yield 1% MoS₂. A 100-ton mill is proposed, to recover 1 ton of molybdenite concentrate daily.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

ONE POUND of molybdenum will produce approximately the same results as two or three pounds of tungsten in making alloy-steels.

GOLD RECOVERY of the Cam & Motor mill in Rhodesia, treating an ore containing antimony and arsenic by roasting and cyaniding, was 83% during 1916.

CORD-WOOD at the Walker copper mine, Plumas county, California, is piled high, leaving 'drifts' and 'cross-cuts' inside so that the wood may be 'back-stoped' under the heavy snow which falls in the district.

AUTOMOBILES have been put to many uses by miners, from hoisting ore to driving a crusher. For sawing wood, we are informed that by attaching a pulley to the rear axle of an auto, power may be transmitted to a saw-bench by belt. The pulley is put on the shaft in place of one of the floating axles, and held in place by a collar fitted between the differential housing and floating axle casing.

MAGNESITE occurs in nature associated with basic magnesian rocks of the peridotite series, such as olivine or its altered form, serpentine. Two distinct types of deposits are known. The more important is the vein or lens type of orebody as distinguished from those deposits known to be of sedimentary origin. The problem is not so much one of the origin of the magnesite itself, as of the origin of the carbonic acid and magnesium of which the mineral is composed.

ALUM is used to purify the water in reservoirs. The alum-cake is made by treating pulverized bauxite with sulphuric acid. These two ingredients are mixed cold and no water is added. The mixture is stirred for five minutes, and is then discharged into a pit in which the alum crystallizes in cakes three to four inches thick. The cake-alum is successfully employed for water purification in place of the liquid alum-syrup previously used for the same purpose.

LEAD-SLAG is a silicate of iron and lime, and varies in color according to its composition. Usually it is black, the darkest being that containing much iron, though when a small amount of ferric oxide (Fe_2O_3) is present it may have a reddish or a greenish cast. Lime has a tendency to make the color lighter, giving the slag a dull stony appearance, and manganese in large amount produces a reddish or amethystine tint, and when the manganese is associated with 20% or more of lime the slag often assumes a resinous appearance resembling zinc-blende. When zinc is present together with some manganese and

much silica, the slag looks like porcelain or some varieties of obsidian. Slag that is black and lustrous owes its appearance to an excess of iron, and very silicious slags have a greenish color.

MANGANESE DEPOSITS, estimated to contain 250,000 tons of ore assaying 87% MnO_2 , are being exploited on the Nicoya peninsula on the west coast of Costa Rica, Central America. The ore will be taken to Philadelphia by way of Panama Canal. Three new steamers are being built for the trade. The Crespi, Keith (United Fruit Co.), Marshall (Dunbar Furnaces, Philadelphia) interests are behind the project.

WATER-WHEELS of the old-fashioned type, commonly known as over-shot wheels are still in use in some parts of California. There is one near Quincy, in Plumas county, 72 ft. in diameter that was built in 1868, repaired in 1880, and is doing good service still. It supplies power to a saw-mill. In the early days of quartz mining in California over-shot wheels were used as a means of power to run many mills, and a few of them may yet be seen at isolated mines.

PHOTOGRAPHS are a valuable aid to a description, particularly that of mines and metallurgical plants. When taking photographs the man with the camera should aim to obtain pictures that will show to the best advantage the object that he wishes to illustrate, giving little heed to artistic effect. Too many forget this, or do not realize that it is not so much a pretty picture that is wanted as one that will show just what is to be illustrated. When taking pictures of open-work structures, such as head-frames or machinery standing out of doors, choose a dull day when the sun does not cast sharp shadows, for these confuse the object and much of the value is lost of what may otherwise have been an excellent picture.

BULKHEADS in mines must be constructed with great care if they are intended to resist the pressure of a high column of water. The higher the hydrostatic head to be resisted, the greater the need for care in the selection of a suitable place for bulkhead, and the more important is caution in the choice of materials and strict supervision in construction. The mistake is occasionally made of placing a bulkhead in a part of a mine where the rock is much shattered, from natural causes. In one instance, after the completion and closing of a bulkhead, and the water had accumulated behind it with increasingly greater pressure as the hydrostatic head got higher, the water spurted into the cross-cut on all sides—not through the bulkhead, but through the fissures in the rock—rendering the structure useless. The rock was andesite, which was fissured from natural causes and shattered by blasting. The choice of this site for the bulkhead was unfortunate, and it may be that the result could not have been anticipated. However, a knowledge of what occurred in this instance may be of service to others who find it necessary to construct a bulkhead underground.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MEXICO CITY

REMARKABLE CONSTITUTION ADOPTED BY CARRANZA'S MEXICAN ASSEMBLY, WITH EXTRACTS THEREFROM.

The work of the Constituent Assembly was completed at Querétaro on January 31, and published as the new Federal Constitution on February 4. The Assembly was made up of 254 deputies, each deputy accompanied by a *suplente* (substitute), according to Spanish custom. The deputies were supposed to be equitably representative of the entire Mexican nation, but the representation was haphazard and unequal, whether calculated on the basis of States or of the density of population. Many deputies were not resident nor even acquainted with the districts from which they were supposed to hail. The November election, by which they were chosen, was mainly a farce. Most Mexicans, knowing that the results were pre-arranged, did not bother to go to the polls, and in the few districts where some popular resident might chance to receive a large vote, he was out-voted by the other municipal *presidentes* (mayors), who made up the returns for the official candidate to suit themselves, often without so much as consulting the ballot-boxes. Such an election is nothing new in Mexico. Indeed, the only election on record which was in any degree a genuine expression of the public will was that under Madero in 1912. The few deputies not of the officially appointed type who appeared at Querétaro with proper home credentials of election were turned over to the tender mercies of the Credential Committee and rejected as 'reactionaries.' This fate befell not only lifelong Liberals, who may have committed the unpardonable sin of holding office under Huerta or the Convention, but also certain independent Liberals who are actually working for Carranza.

That the Constituent Assembly is a hand-picked body of Carrancista partisans and not, as advertised to the world, a "duly-elected convention of representative Mexicans" is, perhaps, of less interest than the character of the new constitution which it framed. This document contains some 20,000 words, hence I will translate only portions of greater interest to foreigners, as involving their persons and rights. The dangerous influence of the anti-foreign and anarchist factions, as prophesied in my letters of January 29 and October 21, 1916, has now become manifest. These factions have introduced into the fundamental law of Mexico their rabid prejudices in the form of many pernicious projects. The Assembly was opened on December 1 by Carranza himself, who presented to it a draft of the proposed constitution. This draft had for its base the old constitution of 1857, with changes, mostly added with the object of legalizing the innumerable arbitrary military decrees which have been the most distinctive feature of the Carrancista régime to date. It is only fair to Carranza to state that his draft was much less anti-foreign and anarchistic than the constitution as finally approved.

Chapter I of the new constitution deals with 'individual guarantees.' It is an expansion of the old constitution, forbidding slavery, peonage, monastic vows, arbitrary imprisonment, confiscation of private property, excessive penalties for crime, retro-active legislation, or interference with the freedom of speech, press, travel, correspondence, occupation, domicile, or worship. The first 26 articles of Chapter I are similar in design to the first ten amendments to the Constitution of the United States, and constitute a bill of rights in a somewhat

more detailed form. Religious acts are, however, forbidden outside of churches or homes, and in time of war the military forces are allowed to demand lodging, equipment, food, or loans from civilians, on terms established by martial law. The following quotations are of prime importance to foreigners contemplating business enterprise in Mexico.

"Art. 27. The ownership of lands and waters inside of the national boundaries pertains originally to the Nation, which has had and has the right to transmit control of them to private individuals so as to constitute private property. This latter cannot be expropriated except for public utility and after indemnification.

"The Nation will always have the right to impose on private property the regulations dictated by public policy, and also to control natural resources capable of appropriation in the interests of their conservation and of an equitable distribution of the public wealth. For this purpose the necessary measures will be taken for the subdivision of the *latifundios* (great estates), for the development of small holdings, for the creation of new centres of agricultural population along with their indispensable lands and waters, for the encouragement of farming, and for prevention of the destruction of natural resources and of damage to them which would injure the rights of society.

"Towns, villages, and communities which lack lands or waters, or have an insufficient quantity for their inhabitants' needs, may acquire them by taking such from adjoining properties, but they must constantly respect small holdings. Thus are confirmed the gifts of lands which have been made to date, according to the Decree of January 6, 1915. The acquirement of private properties necessary to attain the above objects will be under sanction of public utility.

"To the Nation pertains the direct ownership of all minerals or substances which, in the form of veins, beds, masses, or deposits, constitute bodies whose nature is distinct from the enclosing rock, such as the minerals yielding the industrial metals and metalloids, deposits of precious stones, of amber, and of salts formed directly from marine waters, the products of rock decomposition requiring underground extraction; the phosphates utilizable as fertilizers; combustible solid minerals, petroleum, and all other hydrocarbons, whether solid, liquid, or gaseous.

"The Nation also owns the following waters: its territorial seas within the limits fixed by international law; the lakes and lagoons of the seacoast; the natural interior lakes, which are directly connected with constant rivers; the principal rivers or flowing streams from the point where the first permanent water starts toward its mouth, whether they enter the sea or merely cross two or more States; the intermittent rivers which cross two or more States in their principal part; the rivers, streams, or creeks when they form a national or State boundary, and the streams flowing from mine drainage. The beds, channels, and banks of the aforementioned waters are also national property within the limits fixed by law. Any other stream not included above will be considered an integral part of the private property which it crosses, but the utilizing of waters when they pass from one estate to another will fall under the rule of public utility, subject to regulations dictated by the States.

"In the cases listed in the two previous paragraphs, the ownership of the Nation is inalienable and imprescriptible.

and the Federal government may only grant concessions for their use to individuals, or to civil or commercial companies conforming to Mexican laws, on the condition that they install regular work for the exploitation of the elements in question, and comply with all the requirements of the laws.

"The ability to acquire control of the lands and waters of the Nation will be governed by the following rules:

"I. Only Mexicans, by birth or naturalization, and Mexican companies, have the right to acquire control of lands, waters, and their accessories, or to obtain concessions for exploiting mines, waters, or combustible minerals in the Mexican Republic. The Government may concede the same right to foreigners, provided always that they agree before the Secretary of Foreign Relations to consider themselves as nationals with respect to such property, and not to invoke the protection of their home governments for anything relating to it, under penalty of forfeiting to the Nation whatever they may have expended on their concessions. In a belt 100 km. (60 miles) wide along the frontiers and 50 km. wide along the seacoasts, foreigners may not acquire property in lands or waters under any pretext.

"IV. Commercial corporations issuing shares may not acquire, possess, or operate rural estates. Such corporations, which are formed to exploit any manufacturing, mineral, or petroleum industry, or for any other non-agricultural purpose, may acquire, possess, and operate lands only to the extent which may be strictly necessary for the installation and performance of their indicated objects, as determined by the Executive of the Nation, or of the States, as the case may be.

"V. Duly authorized banks, conforming to the banking laws, may loan money on urban or rural property, according to law, but may not own or manage more real estate than is absolutely needed for their own use, except temporarily during the brief time allowed by law, in so far as such properties serve as security for loans.

"VI. Co-ownerships, villages, congregations, tribes, and other popular corporations which *de facto* or by law preserve a communal organization, will have the right to work in common the lands, forests, and waters which they own, or have, or will recover by the law of December 6, 1915. Meanwhile, the law will determine the manner of subdividing these lands in future.

"VII. * * * The laws of the States and Federation, in their respective jurisdictions, will fix the cases where the expropriation of private property may be judged a public utility; and in accordance with such laws the Executive will issue the corresponding decree. The price fixed upon as indemnity for the thing expropriated will be based on its assessed value in the public tax-office, plus 10%, whether this value has been declared by the owner or tacitly accepted by him as the base for paying the taxes. The excess value which the private property may have acquired through betterments made since the last assessment, will be the only part of the price which will be subject to expert appraisal and to judicial determination.

"Art. 28. In Mexico there can be no monopolies of any kind, nor exemption from taxes, except the coinage of money, the telegraph, the radio-telegraph, and the issue of notes by a single bank, which monopolies will be controlled by the Federal government. There are also excepted the copyrights granted to authors and artists for the reproduction of their works, and the patents allowed to inventors for their improvements in the arts.

"Consequently, the law will punish severely, and the authorities will effectively prosecute, all concentration or cornering in the hands of one or of a few, of articles of necessary consumption, with the object of raising prices; every act which tends to overcome free competition in production, industry, commerce, or public service; every agreement or combination, in whatever manner made, of producers, manufacturers, merchants, or common carriers, or of any other public

service, to avoid competition and oblige consumers to pay exaggerated prices and in general, whatever constitutes an exclusive advantage in favor of one or of several persons, and prejudicial to the general public or to some social class.

"Workmen's unions, organized to protect their own interest, will not be deemed monopolies; neither will associations or co-operative societies of producers who, in defense of their own and the general interest, sell directly in foreign markets the national products which are the principal source of wealth in the producing region and which are not articles of first necessities, be deemed monopolies.

"Art. 33. Those are foreigners who do not possess the requisites for citizenship, as set forth in Art. 30. They will enjoy all the individual guarantees afforded by Section I of the present Constitution, but the Federal Executive will have the exclusive right to eject from Mexico, immediately and without trial, any foreigner whose presence he may judge to be unwelcome. Foreigners must not in any manner mix up in politics."

Under 'Title VI,' headed 'Concerning Labor and Social Provision,' we have, perhaps, the most unusual and interesting articles of the whole document, as follows:

"Art. 123. The Federal Congress and the State Legislatures will expedite labor laws adapted to local needs, but harmonious with the following rules which will govern the labor of workmen, day laborers, clerks, domestics, and artisans, and in general all labor contracts:

"I. The maximum duration of a day's work will be eight hours.

"II. The maximum duration of night work will be seven hours. All unsanitary and dangerous work is prohibited for all females and for youths under 16 years of age. For both classes all night work in factories is prohibited, and in commercial houses all work after 10 p.m.

"III. Youths between the ages of 10 and 16 years will have as a maximum day's work a period of 6 hours. The employment of children under 12 years of age may not be the subject of any contract.

"IV. For each 6 days' work the laborer must be allowed at least one day of rest.

"V. Women, during the three months previous to child-bearing, must not be given physical tasks which require any considerable exertion. For the month following a birth, a mother must be given a vacation, with full pay, and afterward be given back her job with all the rights pertaining to her under her contract. During the period of lactation, a mother must be given two extra rest periods of half an hour each, in which to suckle her infant.

"VI. The minimum wage which must be paid a worker will be what is deemed sufficient to satisfy the normal needs of his life, his education, and his honest pleasures, considering him as head of a family. In every enterprise, whether agricultural, commercial, manufacturing, or mining, the workman will have the right to share in the profits, which will be fixed according to sub-section IX.

"VII. For equal work, the same salary must be paid, without regard to sex or nationality.

"VIII. The minimum wage will be exempt from embargo (garnishee), compensation, or discount.

"IX. The determination of the minimum wage, and of the share of the profits, referred to in sub-section VI, will be done by special commission formed in each municipality, subordinate to the Central Board of Conciliation established in each State.

"X. Wages must be paid in legal money, and no substitutes, such as merchandise, tokens, counters, or such like, will be permitted.

"XI. When, from unusual conditions, the legal hours of daily work must be exceeded, there must be credited as wages for the overtime 100% above the normal rate. In no case must the extra work exceed three hours daily, nor must there

be a recurrence of overtime work. Males of less than 16 years and women of no age will not be permitted to perform this class of work.

"XII. In every enterprise, agricultural, industrial, mining, or any other, the owners must provide the workmen with comfortable and healthy houses, for which they may charge rents which must not exceed $\frac{1}{4}\%$ monthly of the value of the real estate. Also, they must install schools, hospitals, and other normal public services of the community. If the enterprise is situated within a town and employs more than 100 people, it will rest under the first of the above-mentioned obligations.

"XIII. Furthermore, in villages where the population exceeds 200, there must be reserved a space of ground not less than 5000 square metres ($1\frac{1}{4}$ acres) for the establishment of public markets and of other buildings for municipal service and recreation. In all such villages the establishment of drinking saloons and gambling rooms is prohibited.

"XIV. Owners will be responsible for the accidents and the professional illnesses of the workmen incurred by reason of or during the performance of their duties; owners must pay the corresponding indemnity fixed by law, whether the results have been death or simply temporary or permanent incapacity for work.

"XVI. Both employers and workmen may organize for mutual protection by forming unions, professional societies, etc.

"XVII. The laws will recognize strikes and shut-downs as the respective rights of workmen and employers.

"XVIII. Strikes will be legal when they have as their object the equilibrium of the different productive factors and the harmonizing of the rights of labor and capital. In the public service, workmen must give 10 days' notice, before striking, to the local Board of Arbitration. Strikes will be deemed illegal only when the majority of the strikers use violence against people or property, and in case of war when the workmen belong to establishments or services dependent on the Government. Workmen in the military factories of the Government are not included under this regulation, because they are part of the national army.

"XIX. Shut-downs will be legal when an over-production makes it necessary to stop work in order to maintain prices at a payable figure, and when the shut-down has first been authorized by the Board of Arbitration.

"XX. The differences or conflicts between capital and labor will be subject to the decision of a Board of Conciliation and Arbitration formed by an equal number of representatives of the workmen and of the employers, with one representative of the Government.

"XXI. If the employer refuses to submit his differences to arbitration or to accept the award of the Board, his contract with labor will be annulled, and he will be obliged to indemnify his workmen to the extent of three months' salary, and to assume any responsibility resulting from the conflict. If the workmen decline arbitration their labor contract will be terminated.

"XXII. The employer who discharges a workman without just cause, either for having joined a labor union, or for having taken part in a legitimate strike, will be obliged, at the option of the workman, to either restore his job or to indemnify him in an amount equal to three months' pay. Also the employer will rest under this obligation when a workman quits because of lack of good faith or because of bad treatment on the part of the employer, whether toward himself, toward his wife, parents, children, or brother. The employer is similarly liable if the bad treatment proceeds from clerks or relatives who work with his consent or tolerance.

"XXIII. The credits of workmen for salary or wages performed in the previous year and for indemnities will have preference over all other debts, in case of insolvency or bankruptcy.

"XXIV. For debts owed by workmen to their employer, his

associates, relatives, or clerks, only the workman himself will be responsible, and in no case and for no reason may payment be demanded from any member of his family; nor may payment of such debts be demanded for the amount of a single month's salary due the workman.

"XXV. The service of finding jobs for workmen will be performed gratis and may be carried on by municipal offices, labor exchanges, or by any other official or private institution.

"XXVI. Every contract for labor outside of Mexico made between a Mexican and an employer living abroad must be legalized by the competent municipal authority and viséed by the consul of the nation whither the workman is to go; with the understanding that, besides the usual conditions, it shall be clearly provided that the expense of re-patriation shall be borne by the employer.

"XXVII. The following conditions, even if written in the contract, will be void and will impose no obligation upon its signers:

"(a). Those which stipulate a length of day inhuman for the kind of work to be performed.

"(b). Those which fix a wage which is not remunerative in the judgment of the Boards of Arbitration.

"(c). Those which fix a time longer than one week for the payment of wages.

"(d). Those which designate an amusement hall, a restaurant, a café, a tavern, a saloon or a retail shop as the place for the payment of wages, except for employees of such establishments.

"(e). Those which imply a direct or indirect obligation to acquire the articles of consumption in certain stores or places.

"(f). Those which allow the retention of wages by fines.

"(g). Those which constitute a renouncement by the workman of the indemnities to which he is entitled for the accidents of work, professional sickness, and damages caused by an unfilled contract or by dismissal.

"(h). All other stipulations which may imply renouncement of any right secured to a workman by the laws for his protection and aid.

"XXVIII. The laws will determine the goods forming a 'family patrimony'; this patrimony will be inalienable and cannot be subject to liens or *embargos*, and will be transmissible by will by means of a simplified inheritance procedure."

In Article 135 it is stated that the Constitution can be amended only on the initiative of two-thirds of the members present and voting in the Federal Congress, and after such initiative has been approved by a majority of the State legislatures.

Such is the gist of this astounding document which puts in permanent legal form the theories and practices of the Carrancista military satraps since 1913. It is the product of the typical native politician who, while physically in contact with some of the wonders of modern times, is mentally groping in medievalism. Shades of Proudhon and Michael Bakunin! What a carnival of confiscation and of subjugation to the working class!

JOHANNESBURG, TRANSVAAL

DETAILS OF A LARGE MINING TRANSACTION.

One of the most important mining deals ever consummated in South Africa has just been announced on the Rand. Solly Joel, head of the Barnato house, has acquired the interest of Sir J. B. Robinson in the Langlaagte and Randfontein mines and estates on behalf of the Barnato group, represented by the Johannesburg Consolidated Investment Co. Robinson's interest in these important properties was such as to secure his control in their management and policy, but the amount paid for this has not been made public. It is placed at between £1,000,000 and £3,000,000. The only other deal approaching this in importance was that of De Beers in 1888,

when £3,246,000 was paid to acquire the diamond claims at Kimberley. The effect of the new transaction will be to place the Barnato group in the front rank of Rand mining houses, and as this firm is interested in important adjoining properties on the West Rand, it is expected that the ultimate effect will be to rehabilitate that part of the Rand in the good opinion of investors, as undoubtedly for some time past West Rand prospects have been on the down grade. The change in control will also do something towards benefiting the whole Rand, because Sir Joseph Robinson has always preferred to play a lone hand in labor and mining, and sometimes in direct opposition to the rest of the Rand. It is, however, expected that the new control will, as previously, fall in line with the Chamber of Mines, and thus ensure a united mining policy for the whole of the Rand. At Langlaagte and Randfontein the change of control will also be generally welcomed, as the policy pursued by Sir Joseph Robinson has never been apparently fixed or consistent, with the result that everything has been unsettled and changes in management throughout the mining staff far too frequent.

The importance of the acquisition of the control of these properties will be gathered from the fact that the capital of the Randfontein Estates Co. is £3,000,000, while it has a debenture issue of £2,000,000. Its holdings in subsidiary Randfontein mining companies are valued at nearly £5,000,000. The estate comprises 31,726 acres. The mining section of the concern is represented by the Randfontein Central Gold Mining Co., with an issued capital of £4,343,700, and debentures amounting to £2,734,900. The tonnage crushed monthly varies from 180,000 to 200,000, yielding gold worth £250,000 and a working profit of £80,000. During last year when the Crown Mines was experimenting with selective mining the Randfontein Central always occupied the first position in the list of gold producers on the Rand, and can always be depended on to run the Crown Mines close in this respect. Only two small dividends have, however, been paid.

The Langlaagte Estate Gold Mining Co. has an issued capital of £886,500, and is one of the pioneers of gold mining on the Rand. The farm was acquired originally in 1886 by Robinson for £6000. Milling operations commenced about two years later, so far over £2,000,000 has been paid in dividends. On the same farm is situated the Langlaagte Consolidated Mines belonging to the Barnato group, and perhaps a consolidation scheme will result from the change of control. It is also possible that some scheme of amalgamation may arise at Randfontein, whereby the Randfontein Deep property, now under the Barnato control, will be effected.

This change of control of the Langlaagte and Randfontein properties is popular on the Rand, where it is hoped that something at least will be done with the Randfontein mines to place them in a satisfactory position among the dividend-payers of the Witwatersrand.

SUTTER CREEK, CALIFORNIA

PROGRESS AT THE NORTH STAR.—ANTIMONY DISCOVERY.

The work of unwatering the North Star shaft of the South Keystone Consolidated Mining Co. has progressed to the 600-ft. level, which is now being drained. Nearly all the work done on the North Star claim during former operations was done on the 600-ft. level; a little development work was done on the 1000-ft. level, and some at 800 ft., so this shaft will soon be clear of water to the bottom, after which the drifts on the 600 will be continued to prospect the several claims of this group, which includes the South Keystone, McIntire, Boyson, and North Star claims, much of which is unexplored territory rich in promise, as surface indications are ideal for a great mine. The intention is to unwater the shaft to the bottom before attempting other work. The North Star is nearly vertical and about 1000 ft. deep, and well situated for quickly proving all of the claims included in the consolidation.

There is known to be a shoot of valuable ore in the South Keystone mine, which joins the Keystone on the South, and it is thought that some of the ore of this shoot may have been mined through workings of the South Spring Hill mine, which lies east of the South Keystone. There are also known to be three veins outcropping in the latter claim, but no development has been done on either of them. On the McIntire claim, which joins the South Keystone on the south, there are two shafts each about 200 ft. deep. In the North Star the shaft timbers have so far been found in good condition, only occasional new sets and the laying of a new skip-track being necessary. Charles H. Colpe, general manager, of the South Keystone Con. Mining Co. was at Sutter Creek this week.

A large deposit of antimony ore has been discovered on Esperanza creek, near Mokelumne Hill, in Calaveras county, by a geologist in the employ of the Federal government. The hills in that vicinity are being scoured by prospectors in search of other deposits.

Contrary to expectations, the new motor for the Old Eureka mine, on which the operation of the new hoisting plant depends, has not yet arrived, and as the plant thus far has nearly reached the limit of its capacity the electrical machinery is anxiously awaited.

JOPLIN, MISSOURI

ORE PRODUCTION HAMPERED.—NEW MILLS.—OKLAHOMA.—TAXES. —COAL-BURNING INSTALLATIONS REPLACE NATURAL GAS.

Cold weather, shortage of water, and a continued lack of sufficient electric power for the motor-equipped plants, have helped to curtail production in the Joplin district during the opening weeks of 1917. Though the output is greater by probably 2000 tons per week than the average maintained before the War, it has been below possibilities by at least a similar quantity. The cold weather has increased the water shortage. Last summer was unusually dry; there was a fairly wet fall followed by a dry winter, so far. Many plants have been working carefully with water for concentration, but when ponds freeze solidly and keep water from flowing back to ponds from tailing-piles numerous plants had to close and wait for warmer weather. The power shortage has been a bother since last summer. If there had been any considerable rainfall, the White River plant of the Empire District Electric Co. would have been able to supply enough to take an overload off the steam-driven turbines at Riverton, Kansas. As it was, these turbines were overloaded, and have, all three of them, broken under the strain. One is hardly repaired when another is out of commission. The company hopes to have repairs completed by March, so that all motor-driven plants can be operated full time.

It was natural that considering the power troubles, and with a doubtful quantity of natural gas available, most new plants are installing coal-fired boilers for power. A number of electrically-driven plants also have changed over to coal, though the coal situation has been doubtful enough to retard such a movement. The largest steam power-plant in the district is being installed by the Oronogo Mutual Mining Co., at Oronogo. It includes one 400 and one 350-hp. boiler, an Allis-Chalmers cross-compound Corliss condensing engine, and a 2600-ft. cross-compound Corliss compressor. The plant complete is to cost \$70,000. At the time it was purchased, the compressor mentioned was the largest in the district. Since it was bought, however, the Chapman-Hosley company, which has taken over the Schoolhouse mine at Carterville, has purchased and is installing one of similar size. Other important additions and enlargements are being made by this concern at this property, which formerly was operated by J. F. Dexter. Its new capacity will be 700 tons in 20 hours. Water-hammer drills have been installed and the mine, which formerly was dusty, is now entirely sanitary. One interesting feature is a 37-hp. oil-engine installed underground for operating a geared

pump. It is the first time such an engine has been used in the district for this purpose.

The Blue Mound Mining Co. has commenced to operate a new concentrating plant in Kansas, just across the State line north from Picher, Oklahoma. The mill cost \$125,000. This may be considered a fair illustration tending to show both the increased cost of mill-building and equipment in this field, and also the tendency toward more elaborate plants. Before the War started, a plant that cost \$75,000 here was the exception; now there are a number, and others that have cost nearly twice this amount. The Blue Mound plant, while modern and of approximately 300-ton per shift capacity, with a sludge department that will house, eventually, 18 tables, does not compare with the Netta plant of the Picher company, at Picher, nor the No. 3 mill of the Coahuila Mining Co., erected during the past six months at Duenweg. Recently the Netta mill established a new record for the district. In 20 hours continuous operation it made 107 tons of zinc concentrate and 6 tons of lead, treating 1400 tons of ore. This

leases in this region, and recently let a contract for 18,000 ft. of drilling. The organization of business men from Columbus, Kansas, who started prospect work near their town, has received no encouragement so far, as out of four holes put down no ore has been found.

Oklahomans are annoyed over a measure introduced in their State Legislature, proposing a 2% tax on the production of all ores. It is estimated that such a tax would mean an assessment on the Oklahoma portion of the zinc and lead region of at least \$200,000 per annum. Missouri mine-owners are also to be taxed by a bill introduced at Jefferson City, which would impose a tax of 4 cents per ton on zinc-blende and lead concentrates and of 1/20 cent on silicate. It is probable some such tax will be levied, as the State must raise more revenue. Mining men are not protesting much.

The Oklahoma districts are monopolizing attention in development, and they deserve such. During the winter there have been few important strikes in the older centres. North-east of Lawton, Kansas, near Waco, Missouri, there is much

THE RED BIRD ZINC-MILL AT CARTERVILLE, NEAR JOPLIN, MISSOURI.

also shows the value of the ground. The Netta is the largest of the four mills erected by the Picher company last summer, and is operated throughout by electricity.

From the standpoint of development interest continues in the Oklahoma portion of the region, with indications that the rich run of ore extends well into Kansas, in the neighborhood of Baxter Springs. Scores of drills are operating in the area between Baxter and Commerce, Oklahoma, and a large number of strikes are reported, most of them unusually rich. As proof that this phrase of "unusual richness" is not boom-talk, it may be noted that an assayer's report on a recent hole put down on the Hartley farm, a short distance south of Baxter, showed 20.5% blende from 195 to 200 ft.; 31.8% blende at 205 ft.; 39.95% at 210 ft.; 43.05% at 212 ft.; 17.07% at 215 ft.; 32.1% at 217 ft.; and 4.80% at 218 ft. A still better hole than this, however, is reported by the Walker Mining Co., wherein the drill encountered ore at 170 ft., and for 23 ft. the average assay was slightly higher than 45%, while for the succeeding 47 ft. it was in excess of 20% blende.

Numerous new companies are being formed to prospect or develop in the Oklahoma field. Among the largest of the more recent organizations is the Tri-State Mining Co., which has been incorporated under the laws of Oklahoma for \$500,000. L. C. Church, of Joplin, who is one of the pioneers in the Oklahoma field, is largely interested in this company. Mr. Church and E. C. Mabon of Miami have recently acquired first lease on 1000 acres of land in Kansas, three miles north of Baxter, and will do extensive drilling. Gatch and Burns, formerly interested in the Granby company before its sale to the American Zinc, Lead & Smelting Co., have acquired large

activity in drilling, and some rich ore has been found. Near Diamond, Missouri, R. L. McGee has completed a new silicate mill on new territory. At Neck City the Missouri Zinc Mines Co. has installed a Pomona pump to drain the old Texmo shaft, which it expects to operate along with the Quick Seven. At Joplin, Mattes Brothers have taken over the Symmes and Dick Turpin mines south-west of the city, and will operate both.

The new Red Bird mill outputs 60 tons of blende and 60 tons of galena concentrate monthly when working but one shift per day. This plant was described in our issue of December 23, 1916.

In spite of the railroad embargo upon freight shipments, there has been little lessened activity in the zinc and lead-ore market for the past week. Prices for 60% zinc ranged from \$70 to \$90, at which figures the ore buyers apparently are willing to take all of the ores they can secure, taking their chances of securing cars for shipment. There is an almost feverish activity in the buying of lead ores, at prices ranging from \$105 to \$110 per ton for 80% lead. There is a greater tendency between the ore buyers and the ore producers to get together on this market. The great preponderance of zinc production over lead makes it feasible to hold zinc ores rather than lead ores when the market shows signs of further advance. With lead selling at such high figures, even the small proportion of this product to zinc is sufficient in some instances to carry the burden of the pay-rolls from week to week and allows the ore producer the privilege of selecting his own week for the sale of his zinc ores at such times as he feels the market situation to be in his favor.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

(Special Correspondence.)—The Goodro mine is installing a 50-ton flotation-plant. The machinery is on the property and a pipe-line and dam for power is completed.—The It mine has 5000 tons of 3% copper ore broken in the stopes and 10,000 tons blocked out.—The Harper syndicate, operating the Westlake mine, is installing a concentrating-plant to handle the low-grade ore containing gold, silver, lead, zinc, and copper. Arrangements have been made to ship the high-grade ore to Butte, Montana.

Ketchikan, February 10.

The discovery of a new placer field in the Tanana valley, 125 miles from Nenana, in what is known as the Tolkat country, which joins the Kantishna district, is reported. Few people are there at present and the district is hard to reach. Fred Houselman is said to have taken \$1000 in gold out during the late fall on Moose creek. The shaft sunk by Houselman is 22 ft. deep, but did not find bedrock, according to the report. A shaft sunk by Gleason and Grant was put down 12 ft., but produced a few coarse colors. They had intended to 'freeze' the hole down through the thawed ground that underlies the surface and which prevents the sinking of shafts to bedrock by ordinary means, but their grub ran out and they had to come in for an outfit.

According to statement of H. P. Warren, of the Alaska Engineering Commission, at Seattle recently, 6500 men will be employed on the railway in the coming season, an increase of 1000. Nearly 60,000 applications are on file for work. From present indications, the railroad's line to Chickaloon in the Matanuska coal-fields will be completed by August 1. All station work on the 14 miles from King's river to Chickaloon was let this winter ahead of time, and the work is being rushed to completion. Plans for the coming season include the construction of all bridges in the Seward division, so that by next fall the old railroad between Seward and mile 71 will be ready for heavy traffic. Preliminary work is under way for the \$300,000 railroad bridge across the Susitna river, at the mouth of Indian creek.

ARIZONA

The finding of rich ore in the Homestead mine, near Walker, has resulted in the determination to sink the shaft to 200 ft. depth. The strike was made 60 ft. from the surface, and has been followed 100 ft. in a drift.

Within the next few days it is expected that the old Hackberry mine, which has been acquired by Gus S. Holmes of Salt Lake, will become one of the regular shippers in the old Hackberry district. The work being carried on there by Mr. Holmes is causing a revival of this old camp. This old property was once the richest mine in the State, producing argentine and oxidized ores. From the oxide zone alone it is said that over \$3,000,000 was produced. At the No. 1, a vertical shaft, a new hoist and compressor have been installed, the mine has been unwatered and ore is being taken out. In cleaning up the mine for development work three cars of ore were taken out and are now on the dump. In the mine there are also several cars of ore ready for stoping and which was stored underground as there was no place for this ore on the dump.

A new wagon-road has been completed to the spur from the Santa Fe road, a compressor has been installed at the No. 2

shaft, ore-bins are being built, and a hoist is being installed. This shaft is down 109 ft. in the vein.

The property consists of 300 acres and extends for over a mile along the vein system. The main shaft is down 500 feet.

During January the Miami Copper Co. produced 1553 tons of concentrate having a value, f.o.b. works, of \$318,628. This compared with values of \$278,513 in December concentrate and \$299,396 in November. Since Miami has been compelled to make monthly statement of its flotation operations its results have been as follows:

	Jan.	Dec.	Nov.	Oct.
Tons feed	124,676	121,493	120,988	102,698
Tons concentrate	1,553	1,480	1,589	1,370
Assay	%	%	%	%
Copper in feed	1.175	1.118	1.157	1.119
Copper in concentrate	43.059	41.521	41.439	40.987
Copper in tailing	0.646	0.620	0.621	0.58

These figures are the outcome of litigation against Miami brought by Minerals Separation Co. for alleged infringement of patents. Trial of the case and argument on appeal have been heard with decision of the United States Circuit Court of Appeals expected in the course of the next two months.

The plan of dissolution of the Old Dominion Co. of New Jersey calls for the exchange of shares of this company for those of the Old Dominion Co. of Maine, on the basis of two for one, or the retirement of the stock of the New Jersey company at \$61.73 a share. There are three companies—the Old Dominion of New Jersey, the Old Dominion of Maine, which is a holding company and owns all but 7000 of the 162,000 shares of the New Jersey company, and the United Globe Co., all of the stock of which is owned by the Old Dominion Co. of Maine. This arrangement necessitates the payment of three corporation taxes, not to mention duplication of clerical work and records, and it will be much simpler to have the one company, the Old Dominion Copper, Mining & Smelting Co. of Maine, which will be both the operating and holding company. This is the ultimate aim of the management, and after the dissolution of the New Jersey company the United Globe company will be dissolved in a similar manner. The Old Dominion in 1916 earned net profits of \$3,532,125 and paid all but about \$12,000 of this to stockholders in dividends. The January production at the mines was less than that of the preceding months, but some good prices have been obtained for copper. Costs at Old Dominion and the United Globe mines are approximately 9½c. and in January probably all of 30c. a pound has been obtained for copper. This brings profits for the month up to around \$600,000, or about \$7,000,000 a year. It is probable that profits for 1917 will nearly reach this figure, as present production is below normal and the condition of the copper market indicates that an average price of 30c. a pound will prevail. If this proves to be so, Old Dominion will earn well over \$24 per share in 1917, against a present dividend rate of \$12 per share.

Deep drilling is in progress at the Miami Consolidated property, one hole being down 400 ft. several days ago, and a second hole nearly as deep.—Work is to be resumed at the Little Jessie in Chaparral district. The mine was worked successfully for several years, during the early nineties, but operations were discontinued when a heavy flood of water came in. With improved modern machinery, Superintendent W. H. Jones thinks he will have no trouble in controlling the water.

The Black Rock (Limited) Mining & Milling Co., operating

12 miles north-east of Wickenburg, is planning to spend \$150,000 in the development of its property. Diamond-drilling will be done.—The Swansea smelter is to be repaired and operations resumed as a custom works. Mining supplies have recently left Parker for the Planet and Copper Zone mines that recently were acquired by the Arizona Consolidated Smelting Co. Construction work is to begin without delay. J. W. Peart is superintendent.—At the Dundee mine in Jerome district another flow of water has been struck, necessitating additional pumping machinery.—A strike of good ore is reported from the Black Diamond mine in the Walker district, south-east of Prescott, where a vein 5 ft. wide runs over \$30 in gold per ton.

CALIFORNIA

(Special Correspondence.)—With the starting on Coffee creek of the Pacific Gold Dredging Co.'s new dredge, recently completed, Trinity county has entered upon a new era of alluvial-gold production. The large acreage already acquired by this company in the Carrville district, on Trinity river, and on Coffee creek will require several more boats, one of which, it is generally understood, will be constructed this year. The same company has a large acreage under bond on the east fork of Trinity river, five miles east of Carrville, also a smaller acreage at Coffee, seven miles west. The Nash deep gravel mine at the head of Coffee creek is also under consideration, if not already bonded. It extends seven miles to Salmon river, and has a large acreage.

The boat is similar in design to that operated by this company on Yuba river near Smartsville, and is built for heavy duty with an especially strong hull. It is 135 ft. long, 60 ft. beam, and 11 ft. deep. The digging capacity is 60 ft. below water-line. There are 87 buckets with a capacity of 9 cu. ft. each, with a speed of 15 buckets per minute. Each bucket, with lip, weighs 2900 lb. The lips and bottom are of manganese steel. Bucket-pins are 6½ in. diam. and of nickel-chrome steel. The revolving screen is 37 ft. long and 7 ft. diam. The perforations in the manganese steel plates are slotted and are from ¾ to 1 in. by 1½ in. The upper tumbler is of nickel-chrome steel with manganese steel cushion-plates; the lower tumbler is of the round type, and of manganese steel. The upper tumbler shaft is 12 ft. 6 in. long, 18 in. diam., and of nickel steel; the lower tumbler shaft, also of nickel-steel, is 6 ft. long and 13½ in. diam. The spuds are 65 ft. long with 4 ft. 6 in. by 2 ft. 10 in. cross-section. The digging-ladder is 118 ft. long. The gold-saving tables are of wood with two decks, and have a total area of 5000 sq. ft. The tailing-stacker is 155 ft. long and of open construction. There are eight motors, the main drive being 300 hp.; high-pressure pump 100 hp.; low-pressure pump 75 hp.; stacker 50 hp.; screen 50 hp. There are two 12-in. pumps and one 6-in. The boat is equipped with crane and car for removing and dumping large boulders. There are no transformers on the boat; all motors have a 2200 voltage. There are three water-tight compartments, one in the bow, one in the stern, and one around the well-hole. The boat was built by the Marion Steam Shovel Co., and erected by the Pacific Gold Dredging Co. Its total weight is 1600 tons. The work of erection was in charge of Oscar Wicks, foreman, and H. G. McNaught. It is operating with H. C. McNaught as superintendent and C. O. Kister as dredge-master.

Carrville, February 20.

(Special Correspondence.)—The Plymouth Consolidated Gold Mines (Ltd.) has issued the following statement of the production and expenses at that property during the month of January:

Tons milled	11,000
Value	\$61,750.00
Work expense	30,077.00
Development	9,695.00
Surplus	21,978.00
Other capital	444.00

Plymouth, February 21.

CHEROKEE. Forty men are engaged in prospecting at this place in Nevada county. The Hammon Construction Co.'s drills have found bedrock*at 240 and 310 ft. depth. The gravel is tested every two feet in depth.

That the mining operations in Nevada county were never on a better footing, says the *Grass Valley Union*, is evinced by the fact of the large number of smaller mines that are being re-opened. The Signal Mining Co., headed by E. M. Taylor, which operates a mine two miles west of Grass Valley has completed installation of a new Cornish pumping-plant, and the water is now drained. Work of deepening the shaft will be commenced.

The Sunset Mining Co. has shipped 2130 lb. of tungsten concentrate that went better than 70% by gravity test, says the *Randsburg Miner*. The lot was purchased by Wigmore & Co. of Los Angeles for Eastern consumers. The shipment represents the residue of five tons of ore taken six miles west of Randsburg from the Evening Sun group of eight claims in the new district below Powell's camp, and is an improvement on a previous shipment made a year ago. The new shaft is down 50 ft. almost vertical, and driving has progressed fully 60 ft. There is now three inches of 40% ore in the bottom of the shaft with numerous little high-grade stringers.

The following individuals and companies have made application to the California State Water Commission for permission to appropriate water for mining purposes:

The La Grange Mining Co., of Weaverville, 10 cu. ft. per second of the waters of Salt creek tributary to Stuart's fork in Trinity county for hydraulic mining.

Charles E. Knox of Berkeley, 20 miner's inches of the waters of Willow and Alkali springs in Inyo county, for use at a quartz mine. By a pipe-line eight miles long it is proposed to carry the water to the mine in the Ubehebe mining district at a cost of \$2000.

Henry O. Bradley of Hornbrook, one cubic foot per second of the waters of Rancheria creek, tributary to Cottonwood creek in Siskiyou county for mining and milling purposes. A pipe-line 500 ft. long will conduct the water to the mine from point of diversion and the water is to be returned to the river after use. The estimated cost is \$6000.

Charles L. Austin of Wilbur Springs, 20 miner's inches of the waters of un-named springs tributary to Sulphur springs in Colusa county for milling purposes at a gold-quartz mine. It is proposed to carry the water to the mine by pipe-line 2½ miles long, the estimated cost to be \$6000.

The United States Smelting, Refining & Mining Exploration Co. of San Francisco, 30 cu. ft. per second of the waters of Red Clover creek tributary to Indian creek in Plumas county, for power purposes. It is proposed to utilize a fall of 1300 ft. and to develop 4300 theoretical horse-power. The applicant has been given until July 1 to file maps and other data necessary to a consideration of the application.

Superintendent Taylor of the Butte mine at Randsburg will put on an additional force. The ore is in sight; the mill can handle it nicely, and the plan is to get it out as fast as possible. The new mill is working well and the water supply obtainable is said to be ample. This new enterprise is only one of many contemplated, and with the influx of many new miners an era of renewed prosperity is assured for this district.

Elden Low was killed in the Pyramid mine in El Dorado county February 20, by being overcome by gas at the bottom of the shaft. His companion, Fred Turuboo, managed to climb the ladder to the 500-ft. level and escaped a similar fate.

CALISTOGA. An unusual development has taken place at the Socrates quicksilver mine near Calistoga. Throughout this mine the mercury occurs mainly in metallic state, though there are also stringers, veins, and bunches of cinnabar, some of it running as high as 60% quicksilver. Recently two faces of ore have been exposed on one level, at a depth of 300 ft., where the vein is 12 ft. wide, running 35%, mostly metallic

mercury. Scattered through the mass is considerable cinnabar. These two exposures are 500 ft. apart. A new 50-ton Scott furnace has been built, which is now in process of drying out. It will require about two weeks longer to get the furnace in proper condition to begin distillation of the ore. It is thought, however, that the Scott furnace may not be well adapted to this class and grade of ore, it being intended for low-grade ores containing cinnabar. The idea of putting in retorts to treat the high-grade material is being seriously considered. Another difficulty that confronted the management was the fact that the miners became badly salivated in the mines. An investigation led to the belief that this was largely, if not wholly, due to the fact that the miners made a practice of smoking while on shift. Smoking was prohibited and since then salivation has practically ceased. There is also a mining problem to be solved; that is to prevent the almost inevitable loss due to the presence of so large an amount of native mercury in the ore, much of which falls out on the floor of the drift when the ore is blasted. This difficulty will probably be overcome by covering the floor with canvas at the working places, and protecting the canvas by placing planks over it.

An ample supply of water for continuous use in mining now appears assured in northern California. There was six feet of snow on the level at Truckee on February 22, and it has continued to snow almost constantly ever since, so the outlook for an abundant water supply during the year is good.

The Eagle-Shawmut mine on the Mother Lode, three miles east of Chinese, in Tuolumne county, has been bought by the Tonopah-Belmont Mining Co. The mine has been operated since 1893 by John Rosenfeld's Sons, of San Francisco, and is one of the large and deep gold mines of California. It is worked through a shaft 2300 ft. deep and is equipped with a 100-stamp mill, chlorination plant, and other necessary accessories of modern gold mining.

Louis Japoni, a miner, was drowned in the shaft of the Rawhide mine, in Tuolumne county, on February 22. He apparently was overcome by gas and fell into the sump.

COLORADO

(Special Correspondence.)—The yearly report of the Portland Gold Mining Co. shows a net profit of \$768,809.84. Dividends paid during 1916 amounted to \$420,000. Total production to date from this property amounts to 2,814,043 tons of ore of a gross value of \$43,844,865.41. The total amount of dividends paid to date is \$10,597,080. The heading of the Roosevelt drainage tunnel is now within 1600 ft. of the west side-line of the Portland property. The tunnel will cross the Portland property at an elevation of 8112 ft. above sea-level, or 164 ft. below the bottom of No. 2 shaft, and below the 19th level.

Victor, February 20.

IDAHO

A snowslide at the North Star mine, 12 miles north-east of Halley, in Wood River district, on Sunday resulted in the death of 15 men and the injury of others. The slide destroyed the bunk-house, compressor, and warehouse. Ninety men were at work in an attempt to rescue the men buried in the snow, but the work was ordered stopped, as there was great danger of a second slide, which, should it occur, would engulf the entire rescuing force. The mine is operated by the Federal Mining & Smelting Company.

(Special Correspondence.)—BANKS. The Alpine silver mine near here is being developed by John A. Percival of the Interstate-Callahan Co., under the direction of Frank E. Johnesse.

BRUNZELL. The Sunnyside mine is being operated by John M. and H. W. Baker, formerly of the Baker Mines Co., of Cornucopia, Oregon, and a 30-ton ball-mill is being added to the equipment.

BURGDOFF. The Mount Marshall tunnel has cut the vein on the Mt. Marshall group at a depth of 1500 ft., and it is reported that gold ore running from \$40 to \$50 has been found.—The Sherman-Old Corporal mine has been purchased by L. T. Holte, an Alaskan miner, and a 30-ton mill erected. Since October 24 this mine is reported to have turned out about \$100,000. The high-grade ore carries silver-gold, tellurium, besides the metallic gold.

ELK CITY. Seattle parties have bonded the Gilt Edge and Coeur d'Alene groups in the Ten Mile district. There is considerable ore developed in both of these properties.—The Homestake mine, owned by James Pneman, has been bonded to Sacramento people for \$30,000. This property was the first discovery, in 1896, in the old Badger camp, and has been extensively developed by adits run on the vein.

IDAHO CITY. The Lucky Boy mine, in the Gambrinus district, is installing a 100-hp. Diesel engine and electric generator. This power will be used to operate the mine and milling-plants. A Marathon mill is also being installed.

MOUNTAIN HOME. The Reber mine, near Pine, is being unwatered by a syndicate of San Francisco capitalists, headed by M. L. Requa. The shaft is 400 ft. deep and there are about 3500 ft. of levels to be drained. This property has been idle for many years.

MULLAN. During the fourth quarter of 1916 the Consolidated Interstate-Callahan company made a profit of \$747,131. There was shipped to smelter 3476 tons of 48.1% zinc ore, 297 tons of 16.7% lead ore, 13,676 tons of 45.65% zinc concentrate, and 1111 tons of 23.3% lead concentrate. The total was 18,560 tons, containing 16,424,704 lb. of zinc and 1,286,670 lb. of lead. The net value on cars was \$999,025. Costs totaled \$6.065 per ton. The mill treated 33,726 tons averaging 24.75% zinc, 2.1 oz. silver, and 6% lead. The recovery was 81%. Dividends amounted to \$697,485.

NAMPA. The Sinker tunnel at 6700 ft. from the portal has cut the Golden Chariot vein, at a depth of 2400 ft., and 700 ft. below the old deepest workings on this famous property on War Eagle mountain. These old mines have been idle and filled with water since 1878.

The Oro Grande Gold Mining Co. at Sites, is to equip a new mill having two tube-mills, and a cyanide plant. The old machinery is to be overhauled and remodeled as far as necessary.

MICHIGAN

The stockholders of the Tamarack Mining Co. are to hold a meeting March 16, to vote on the question of selling the Tamarack property to the Calumet & Hecla.

HOUGHTON. The coal shortage promises to become more serious, and the larger companies are arranging to get fuel by rail. The Calumet & Hecla contemplates erecting coal-handling equipment on Torch lake similar to that at Duluth and other Lake points. Bad weather curtailed copper production during February.

During 1916 the Copper Range company's net profit was \$6,078,189, a gain of \$2,514,427 compared with that of 1915.

MONTANA

BUTTE. Zinc-lead-silver ore is being shipped by the Butte & Great Falls company's Neihart mine to the Washoe reduction works. Underground conditions are good.

KENDALL. The Barnes-King Development Co. has issued its report for 1916, including the remarks of the manager G. T. McGee. Net earnings from the mines were \$139,671, less \$43,332 for losses at the Piegan-Gloster, rents, etc., leaving \$96,338 net. Dividends paid totaled \$60,000. On December 31, 1916, bullion, cash, etc., amounted to \$109,783, while liabilities included notes payable \$75,000. The 1916 profit was \$51,630 less than in 1915, due to a decrease in tonnage and gold from the North Moccasin and a larger loss from the Piegan-

Gloster. The latter is now yielding better ore. Option payments on the Shannon, aerial tram, crusher, and \$100,000 payments for the Kendall drew heavily on the treasury, so \$90,000 was borrowed. Of this \$15,000 has been repaid.

The North Moccasin mine yielded 33,715 tons of \$8.65 ore. The recovery was 86.5%. The Kendall lease produced 14,918 tons averaging \$2.50 per ton. The Piegan-Gloster mill was remodeled, and is now treating 174 tons daily with 95% extraction of the gold and 68% of the silver. During the year it treated 35,536 tons of \$9.48 ore, at a cost of \$1.465 per ton. The tram from the Shannon mine to the Gloster mill was constructed at a cost of \$25,600. Cost of mining, development, and crushing at the Shannon is \$2.53 per ton.

The Woodrow Wilson mine in the Rimini district is under option to the Barnes-King for \$120,000. Prospects are good.

Bailing continues at the shaft of the Colusa-Leonard Extension Co. and within 10 days sinking from the 800 to the 1600-ft. level will begin. The water has been lowered to below the 600 by tanks and in addition to this method of unwatering, pumps shortly will be in commission which will expedite the work. This work is under the direction of the Tuolumne Copper company which has a development contract with the Colusa-Leonard Extension company for the sinking of the shaft and the cross-cutting on the 1600-ft. level to the north and south side-lines of the group of claims embraced in the holdings of the Syndicate Copper company. For this development the Tuolumne company will receive 51% of the Syndicate stock, the balance being owned by the Colusa-Leonard company. In addition the Tuolumne company has 265,000 shares of Colusa-Leonard stock. It is probable that an agreement will be reached between the Tuolumne and the Colusa-Leonard companies whereby driving operations west on the 700-ft. level of the Spread Delight vein may be continued into the Colusa-Leonard. The west breast of the drift is a short distance from the east end of the Colusa-Leonard group and there is little doubt that the ore continues into the Colusa-Leonard territory. It is expected that another arrangement will be reached for cross-cutting the Spread Delight vein on the 500 and the 800-ft. levels of the Colusa-Leonard and another fissure lying close to the shaft, which in the Main Range property adjoining, shows a shoot of ore ranging in width from two to three feet of high-grade ore. The Tuolumne, in February, shipped 1000 tons of ore from the Sinbad shaft as compared with 700 tons in January, despite the fact of February being a short month. From the Tuolumne shaft the tonnage for February was expected to approximate 4000 tons.

The Furnace Creek Oxide Copper Co., that ten years ago was organized to operate mines in the Death Valley region of California, and failed to find anything of value in the claims explored by the company, has now acquired by lease and option the Eclipse-Argo mines, comprising a group of five claims at Hell-gate canyon, 30 miles east of Helena. The purchase price is stated to be \$225,000, of which \$50,000 was paid in cash January 15. The balance is to be paid in five installments of \$35,000 each, at intervals of four months after the first payment. A crew of miners has been employed on development work, and for some time the present owners have shipped five cars of ore monthly to the Washoe Reduction Works, at Anaconda, for which they received from \$3000 to \$3500 per car. Since July 1, 1916, the mine has produced a total of 1052 cars of ore for which the smelter paid \$114,071.

NEVADA

ROCHESTER. To develop an orebody in its Shepherd No. 1 adit the Rochester Combined Mines Co. is driving a lower adit. During May a 300-ton plant is to be commenced, to be ready early in November. Cash on hand is \$80,000.

Lane and Ishway, working claims north of Groom camp, near Pioche, have found a vein that assays \$14 gold. The shaft of the Groom North Extension company, situated north of the Groom mine, is down 40 ft. It is intended to cut the

main lode on the dip. After driving 50 ft. the company will install a gasoline-hoist.

The caterpillar train and trucks are moving again and ore is going steadily from the Groom mine to market. The snow melted slowly and no time was lost through muddy roads. The distance to Indian Springs station is 60 miles, and the Packard and Sauer trucks have been able to make a round trip (120 miles) in 24 hours, on several consecutive trips during the past ten days.

The old Highland Mary mine at Austin is to be operated by Frank McLaughlin and George Gordon, who have a lease on the property from the owner, the Nevada Equity Mines Co.

Another attempt is to be made to re-work the large tailing-pile from the Comstock mills, four miles from Dayton. The tailing covers several acres of ground to the depth of 2 to 12 ft. and assays 3 to 4 oz. silver and a little gold. It also contains sodium chloride, copper sulphate, mercuric chloride, and quicksilver, but it is now believed that the metallurgical treatment has been solved successfully, though former attempts failed. A plant having a capacity of 150 tons daily is to be built by the Placer Recovery Co.

The hoisting-plant, change-house, and blacksmith-shop at the Great Western mine, two miles west of Tonopah, were destroyed by fire on February 20. The fire was attributed to an overheated stove in the change-house.

Water has been lowered to the 2900-ft. level of the Union Consolidated mine, on the Comstock. Work is being pressed with vigor on several of the north-end mines, in fact, work along the entire Lode is being stimulated by the recent rise in the value of silver.

Goldfield desires to secure a school of mines, such as is maintained by the State at Virginia City and Tonopah. A bill to secure such a school was introduced in the Senate February 20 by Senator Elliott. The measure provides for paying a principal \$2400 yearly and authorizes \$3000 expenses in maintaining the school.

It is reported at Tonopah that the old lead-silver mine at Tybo, in central Nye county, is to be re-opened. Walter Trent of Reno, president of the Trent Engineering company, has for the past six months been perfecting arrangements for operating the principal group of mines, which have been favorably reported upon by competent engineers. Barney Baruch, of New York, is said also to be interested and with him are associated other prominent and wealthy New York mine investors under the name of the Louisiana Consolidated Mining Company.

The MacNamara Mining company at Tonopah has resumed work on the 300-ft. level, through the West End workings, at a different part of the property than that where the work lower down is being done, the two working-places being about 1000 ft. apart. Some ore was exposed on the upper level near the West End line, and arrangements have been made to mine this in an economical manner through the West End workings. Shipments, therefore, are coming from two places in the mine at the present time.

NEW MEXICO

The Burro Mountain Copper company, after experimenting with a small leaching-plant at Tyrone the past three years, has found that method to be successful in treating the low-grade copper ores. During the latter part of 1916, the company constructed a modern leaching-plant at a cost of \$85,000, which has been operating satisfactorily. The present leaching-plant is to be greatly enlarged. Plans have been agreed on and work will go forward without delay.

(Special Correspondence.)—The Granite Peak Copper Co., of Granite Peak, Grant county, New Mexico, that was recently organized, will install machinery at its mine.—The Copper Queen Mining Co., of Bisbee, Arizona, plans to build a concentrating-mill of daily capacity of 3000 tons. It will also install steam-shovels to remove the overburden of Sacramento

hill.—The Nacozari Consolidated Copper Co., of Nacozari, a subsidiary of the Copper Queen, operating at Sonora, Mexico, is about to install the flotation system in its mill, and the Montezuma Copper Co. will equip its concentrator with new tables and slimmers at Nacozari.—The Greater Miami Copper Co. will build a mill on Mineral creek, near Globe.

Douglas, Arizona, February 22.

The Mogollon Mines company cleaned up approximately 16,000 oz. gold and silver for the first half of February. Driving on the 900-ft. level is now advancing at the rate of 9 ft. per day, in a single heading. This is the fastest work ever done in the district. Leyner drills are used and both drilling and tramping is contracted.

Elmer James, operating the Trilby property, has opened a face of ore on the lower-tunnel level. This vein is the extension of the S. Johnson which is being advanced in ore on the lower level toward Trilby ground.

Socorro Mining & Milling company shipped sixteen 100-lb. bars of bullion for the first 15 days of February. The mill is handling better than 200 tons per day.

Considerable prospecting is being done south of White Water. Some good assays are coming in and a number of claims have been located.

Preparation are being made to resume work on the Meerschau mines, 40 miles north of Silver City. These are the only deposits of meerschau known in North America. Operations will be under the direction of J. P. Porteus.

UTAH

GOODWIN, formerly Gold Hill. According to the Salt Lake *Mining Review* the Deep Creek district, Tooele county, into which a railway is being constructed, has a promising future. Although minerals were discovered 60 years ago, lack of transportation facilities discouraged everybody. The elevation is 4500 ft. upward. Surface mineralization is good. Ore is not confined to fissures, but occurs in the lime-porphry contact also. The Western Utah Copper Co. has the largest property, after which come the Calaveras, Pole Star, M. R. Evans, Queen of Sheba, Garrison Monster, and others.

Fifty Greek pick-miners were paid off at the Standardville coal mines February 20, when they demanded an increase of wages on threat of striking. The increase was refused by the company on the ground that a 10% raise had been accepted three months ago with an agreement that no further increase would be asked within at least a year from that time. "Three months ago we granted an increase of 10% to the pick-miners without advancing the pay to the inside men and machinists," said F. A. Sweet, president of the company to the *Deseret News*. "This increase placed our pick-miners considerably in advance of those of other mines, some of them making as much as \$11.50 per day, and the poorest making \$6.50. Of course they did not work every day, but during January some of them earned \$228, others ranging below that figure. Our increase was given on the men signing agreements not to ask additional raises within a year.

"The demand for an increase again within three months of that agreement was occasioned by the recent increase of the Utah Fuel company. This company after the increase was paying its pick-miners only as much in some instances as we were already paying, while at the Clear Creek mine the rate still is five cents a ton under our rate.

"This new demand on the part of our pick-miners was apparently the first step in a movement to make the companies concede another blanket increase. There is no other class of laborers in the country making such wages as our pick-miners now, and we felt perfectly justified in declining the demand. We look for our action to settle the matter in a short time."

ROBERT R. SCOTT, a pioneer miner of Amador county, California, died February 23, aged 78 years. For many years he was a hoisting engineer at the Kennedy mine.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

R. A. KINZIE is at Phoenix, Arizona.

CHARLES JANIN is on his way to Siberia.

W. DEL. BENEDICT is at the Palace Hotel.

J. NELSON NEVIUS has been inspecting mines in Mojave county, Arizona.

NELSON DICKERMAN has gone to Guatemala, expecting to return early in May.

SAMUEL W. COHEN has his office now in the Dominion Express building at Montreal.

R. S. WICKETT has succeeded A. M. HAY as president of the Trethewey Silver Mines Co. at Cobalt, Ontario.

THOMAS H. LEGGETT was at Los Angeles lately, on the occasion of a mine examination in southern Nevada.

A. B. W. HODGES has returned to Los Angeles after visiting old friends in British Columbia, as far north as Anyox.

EDGAR A. COLLINS has been appointed manager of the Ridder mine, in the Altai, Siberia, and will proceed thither in April.

WILLIAM F. DUTHIE succeeds ALEXANDER BURRELL, deceased, as manager of the Argo mine, of the Furnace Creek Oxide Copper Co., near Helena, Montana.

THOMAS N. MILLER has been appointed general manager for the Blair Cambria Coal Co. and the Altoona Northern Railroad Co., with headquarters at Altoona, Pennsylvania.

FRED. G. FARISH has resigned as manager of the Lluvia de Oro Gold Mining Co. and has taken the management of the Mineral Hill Consolidated Copper Co., Tucson, Arizona.

J. W. WARFORD, for four years past assistant manager for the Original M. & M. Co., at Clearinghouse, has resigned his position. He will sojourn for a brief period at Alameda, California.

CLYDE T. GRISWOLD is examining oil-lands in Oklahoma; F. G. CLAPP is in Wyoming; M. L. FULLER is touring the South; ERNEST MARQUARDT is studying the southern and central fields of Oklahoma; and E. B. HOPKINS is in Mexico.

ALEXANDER BURRELL died suddenly at the Argo mine, near Helena, Montana, on February 13. He was born at Edinburgh, Scotland, in 1851, and came to Chicago in 1856. He first engaged in mining in Illinois, operating a coal property. In 1888 he moved to Marysville, Montana, and entered the service of the Montana Mining Co., which worked the famous Drumlummon mine. In due course he was promoted to general manager and continued in charge until 1913, when the company ceased to operate. In the early part of this year he was appointed manager for the Furnace Creek Oxide Copper Co., operating the Argo mine, near Helena, Montana. He was a capable engineer, a man of high character, and a good citizen.

The annual general meeting of the FARADAY SOCIETY was held at London, December 18. Sir Robert Hadfield was elected president. The report of the council states that in spite of difficulties consequent on the War, it was found possible to hold two general discussions in the year under review, one on 'The Transformation of Pure Iron' and the other on 'The Corrosion of Metals: Ferrous and Non-Ferrous.' The symposium on corrosion has been characterized in an American journal as the most valuable collection of papers that has yet appeared on this subject in England. The report indicated that the Society had been able to be of some service to the Government in connection with the War, and it states that besides those of its members who are on active service, a considerable number of the officers and members are serving on the various Government boards and panels that have been constituted since the beginning of the War by the Admiralty, Ministry of Munitions, and Board of Education.

THE METAL MARKET

METAL PRICES

San Francisco, February 27.

Antimony, cents per pound	24
Electrolytic copper, cents per pound	36
Pig lead, cents per pound	9.50—10.50
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	\$135
Spelter, cents per pound	12
Tin, cents per pound	47.50
Zinc-dust, cents per pound	18—20

ORE PRICES

San Francisco, February 27.

Antimony, 50% metal, per unit	\$2.00
Chrome, 40% and over, f.o.b. cars California, per ton	18.00—20.00
Magnesite, crude, per ton	8.00—10.00
Tungsten, 60% WO ₃ , per unit	17.50—18.00
Manganese, 50% (under 35% metal not desired)	29.00

Manganese ore, 40 to 45%, sells f.o.b. Chicago at 55c. per unit with a penalty of 50c. per unit for more than 8% silica.

New York, February 21.

Tungsten: The uncertainty of arrivals from the West has made premium prices possible. Scheelite is in demand, and has brought \$17 for immediate delivery. For ferberite \$18 per unit has been realized. Wolframite has recently been sold at concessions, but \$16 is declared to have been the minimum, and most of it went well above that figure. The foreign demand is good, and unless stocks are soon replenished a stronger market may be looked for.

Molybdenum: The freight congestion has interfered seriously with deliveries, and complaints are heard in many directions. The ore is scarce, and brokers decline to give a quotation. The last was \$1.80 per lb. for 90% concentrate.

Antimony: This ore is held at \$2.50 per unit, but no business is reported.

EASTERN METAL MARKET

(By wire from New York.)

February 27.—Copper is strong but quiet. Lead is quiet, with the railroad situation somewhat easier. Spelter is stagnant.

June	40.26	42.07	Dec.	38.71	42.55

Owing to the arrival of tin and sales to realize, the market has taken a downward turn, with little inclination on the part of the buyers to come into the market. On the other hand, sellers not being sure about replacing of lots sold, in view of the submarine danger, are reluctant to dispose of this holding, and spot tin is quoted at 49 to 50c., with Banca tin about 47 cents.

ANTIMONY

The New York antimony market is firm. Spot and early March delivery is hardly obtainable. Thirty cents has been paid for a quantity for delivery prior to the middle of March and spot is quoted at 32c. The needle antimony is offered at 12c. for spot and about 10c. for shipment.

PLATINUM

Price of platinum, New York, is \$105 per ounce for soft metal and \$111 for hard.

Eastern Metal Market

New York, February 21.

The paralysis of freight transportation has created an abnormal and most unusual condition in all the metals, especially lead, zinc, and antimony. The break-down of the railroads, with the consequent marooning of freight cars all over the country, has created a dire scarcity of stocks on the Atlantic seaboard. As a result the quotations for spot copper, lead, and antimony have soared, and buyers whose needs forced them into the market have been squeezed. Future deliveries have been almost dormant for the reason that consumers realize that prices will drop when the freight difficulties are smoothed out, and the many shipments on the way begin to arrive. With regard to spot prices it is not fair to call them the market, for not much is doing.

Prompt copper is quoted at 36c. to 37c., with the metal scarce, but in light demand.

Zinc consumers are paying but little attention to buying, meanwhile prices are firm with premiums asked for spot.

Nearby lead is extremely scarce, and 10.25c. has been paid for odd carloads which could be delivered immediately.

Tin is quiet and easier.

But little is doing in antimony; the price, however, hangs around 30c., duty paid for prompt delivery.

In both steel and iron, the railroad situation has caused a spot market to develop. Pig iron has been advanced 50c. to \$1 per ton, and higher prices are asked for various steel products. Ordinary tank plates are now uniformly quoted at 5c., Pittsburgh. Ship plates are in enormous demand at 6c., Pittsburgh, some of the mills finding it impossible to quote on thousands of tons. Inquiries call for shipments of ship material in 1918 and the early part of 1919. In the past two weeks the railroads have placed orders for at least 300 locomotives. The roads are also buying bridges extensively with a view to strengthening their lines for heavier trains, as well as for commonplace improvements.

It must not be supposed that the activity of the German submarines is entirely responsible for the bad railroad situation. It is a factor, but one not to be compared with the shortage of cars and power, lack of adequate labor and weather conditions.

COPPER

The price of prompt electrolytic is somewhere between 36c. and 37c., but not much is doing, and those actually engaged in the trade find it difficult accurately to gauge the situation. A producer's representative states that there is a little more demand for third quarter, but that, all told, it does not amount to much, while for fourth quarter there is no demand. This interest quotes July at around 32c., and third quarter at 30.50c. to 31.50c., and takes the stand it has nothing to offer prior to July. Second hands, on the contrary, have metal to offer from prompt to July. They quote March at 36c. to 36.50c., and second quarter at 34c. to 34.50c. Prompt electrolytic was bought February 19 at 36.12½c., New York, and the following day some of the same metal—about 500,000 lb.—was offered at 37c., but found no taker. There are those who predict 40c. copper if the railroad situation does not improve, inasmuch as consumers will run short and be obliged to buy where they can and at what price they can. Eastern trunk lines in the past two or three days have been giving preference to the movement of food-stuffs, this being done for obvious reasons. Sheet copper was advanced, February 18, to 44c., base (up 2c.) Copper wire for prompt delivery is difficult to find at 42.50c. Needless to say, the refineries are finding it difficult to obtain adequate deliveries of raw materials and their output is being curtailed. It is figured that the February production will not

exceed 180,000,000 lb., although there is capacity for turning out 220,000,000 lb. per month. The London market for spot electrolytic advanced £1 yesterday to £150, against £147 a week previous. The exports, February 1 to 21, totaled 20,394 tons.

ZINC

While spot zinc is scarce, and there have been many reports of fancy prices for immediate delivery, consumers have been curiously indifferent to the state of affairs, at least they have appeared to be, and the market has been quiet. Practically the only business reported has been in February and March delivery. For spot delivery, 12c. is said to have been paid, but confirmation is lacking. For prompt shipment 10.50c., St. Louis, was paid yesterday, while March was quoted at 10.25c. to 10.37½c., and second quarter at 9.75 to 10c., prices which probably could have been shaded a trifle. Brass mill special commands a premium of about 1c. The lack of interest in futures is undoubtedly due to the fact that consumers expect prices to decline when arrivals from the West become more regular. On the part of the producers there is disappointment that prices have not gone to higher levels, especially in view of the flight in copper. The exports February 1 to 12 totaled 6948 tons. The London quotation is unchanged at £47, the price of a week ago. Sheet zinc is without change at 21c. per lb., f.o.b. mill, carload lots, 8% off for cash.

LEAD

Spot and prompt lead is difficult to find on the Atlantic seaboard, and with little or none arriving, it is natural that those in need should pay fancy premiums for immediate delivery. For March shipment, 9.25c. was asked a week ago, and on February 17 consumers paid 9.75c. for the same position. Within the past few days 10.25c. was paid for a carload of spot, and since then, according to report, 11c. and higher has been bid. At 10.25c., the price is the highest since the Civil War, but not much has been done at this level and it is hardly fair to call it the market. The slow and halting deliveries from the West are entirely responsible for the situation. The A. S. & R. Co. continues to quote 8.50c., New York, and 8.42½c., St. Louis, but it is not selling at these figures. The exports February 1 to 21, totaled 365 tons. The London spot quotation, as compared with a week ago, is unchanged at £30 10s.

TIN

Several influences have contributed to an easier tin market. First of all, none of the metal has been lost at sea through the activity of submarines. Secondly, consumers are well covered, as indicated by the large deliveries of last month. For these reasons they are evidently of the opinion that their best course is to stay out of the market and wait for prices to come down. In the past week considerable pressure to sell has been discerned, and the quotation for spot Straits has dropped from 53c. a week ago to 48.75c., yesterday; with March and April deliveries offered at 45.75c., but not stirring consumers to action. The week has been dull and uninteresting. Since the first of this month 3000 tons has arrived, and there is now afloat 3048 tons.

ANTIMONY

Scarcity again tells the story. Shipments in transit from the Pacific coast have been months on the way, yet there is no telling when they will arrive. Meanwhile, spot Chinese and Japanese metal is held at 30 to 32c., duty paid, but there are few buyers. Substantial arrivals will quickly ease the market.

ALUMINUM

No. 1 virgin aluminum, 98 to 99% pure, is dull but firm at 57 to 59c. per pound.

EDITORIAL

T. A. RICKARD, Editor

WE publish a portion of the oral argument in the Miami appeal at Philadelphia. Our readers will follow with interest the colloquy between the Court and Mr. W. H. Kenyon, speaking for Minerals Separation.

UNITED VERDE EXTENSION is the latest word of mining romance. The prospect that was deemed worthless a couple of years ago earned \$6.938,101 in profit last year, equivalent to \$6.60 per share. The management estimates the reserve at 1,000,000 tons of 16% copper ore.

GENTLE roasting makes a pleasant noise, if one may judge from the performance of *The Daily Fume*, two copies of which have filtered westward. The hot air that blew through the official organ of the Institoot must have warmed the cold feet of the stand-patters and melted the hard hearts of the kickers. The scrap promoter sends his compliments to his protemporary at New York.

MINING MEN were represented among the victims on the 'Laconia' by William Eva, a prospector from Bishop, California, and the ladies Hoy, the mother and sister respectively of Mr. Austin Hoy, representative in London of the Sullivan Machinery Company. The latter is well-known to many of our fraternity and will receive their sincere sympathy, heightened as it is by his impulsive action in offering his services as a soldier.

MANGANESE is marketed chiefly at Pittsburg, although ferro-manganese is extensively made at the great steel plants near Chicago, by the Maryland Steel Co. at Baltimore, by the Midvale Steel Co. at Philadelphia, and in the Birmingham district, Alabama. More than 50% of the manganese imports into the United States enter at Baltimore, partly due to an enormous development of the steel industry at that city, and partly to the fact that Baltimore is the nearest Atlantic port to Pittsburg.

IN a recent issue we published a copy of the peremptory letter sent by the Minerals Separation people to the users of the flotation process. It appears that this letter was sent to some mining companies that are not using and never intend to use flotation, for example, the Kennedy Mining Co. at Jackson, California, in the Mother Lode region. The manager of the Kennedy mine received the peremptory demand of the Minerals Separation people for specific data concerning his milling operations, and this was followed by the threat of a suit

for injunction. Certainly, Minerals Separation has acquired a fatal facility for irritating those engaged in mining.

LABORATORY results of an undigested kind are now being published at short intervals from sundry laboratories of research. These tabulations of results, without incisive comment or definite inferences on the part of the experimenter, renders such publication of small importance. What is needed is a statement of the deductions that may be made from such tests, with emphasis upon such of them as have clear scientific or technical significance, so as to indicate the proper direction for further investigation.

FLOTATION has indeed arrived if it is served with the soup, as was done at a banquet at Colorado Springs when the local Chamber of Commerce dined at a table on which a miniature flotation-machine was exhibited in actual operation. We do not know that this example of levitation added to the gayety of the occasion or that the bubbling stimulated the spectators to unusual hilarity, but it must have excited their intelligent interest in a process that is likely to be the means of expanding the commerce of the region tributary to Colorado Springs.

AMONG the articles the importation of which is prohibited by the British decree of February 24, as announced in Mr. David Lloyd George's speech of February 23, we find "Books, and other Printed Matter, including posters and daily, weekly, and other periodicals, exceeding 16 pages in length." This seems to include the MINING AND SCIENTIFIC PRESS, which has a considerable number of loyal subscribers among the mining engineers resident in London. We shall have to prepare a special edition of our paper so as to comply with the new British regulations, the purpose of which is obvious, namely, to save tonnage. Meanwhile we shall hope that the ferry service across the Atlantic may be restored shortly to its former speed and safety.

REFERRING to the registering of British mining companies in other countries, it appears that the Board of Trade may prevent such a transfer. Aramayo, Francke Mines, Ltd., a company operating tin and wolfram mines in Bolivia, sought to evade the burden of taxation in England by transferring the business to a new company incorporated in Switzerland. The Board of Trade applied for the appointment of a controller in order to stop the transfer. The order was granted and the appeal against it was dismissed. No offence is

charged against the officials of the company, but the British authorities suspect that if the English company changes its domicile to Switzerland it could, under Swiss law, transfer shares and pay dividends to alien enemies. Here is one of the ways in which the War affects the business of mining.

DISCUSSION this week starts with a letter on the flotation of gold ores by Mr. F. A. Beauchamp, who is particularly qualified to deal with such matters because he has been engaged in flotation work, both in mill and laboratory, since 1902, having begun his acquaintance with the process at Broken Hill. He gives the results of tests made on ore from the North Star mine at Grass Valley and suggests that it will be worth while to try flotation on the Rand. The State Geologist of New Mexico, Mr. Charles T. Kirk, records his protest against a 'wild-cat' that is likely to prove voracious. Mr. C. T. Van Winkle returns to the charge, replying to Mr. David Cole. We look forward to the publication of information from the Inspiration mine that will settle this controversy, but we shall be surprised if the results of further tests do not allow latitude of interpretation. A kindred subject, that of the Krupp ball-mill, is discussed by Mr. W. E. Simpson, writing from Canada, but backed by much metallurgical experience in Western Australia. A young Californian engineer writes a timely letter on the occurrence of manganese in California, apropos of an article we published on manganese deposits in another State. This is particularly timely and may be read in connection with the article on manganese in Brazil. Finally Mr. J. D. Hubbard, a metallurgist known to us, makes a friendly protest against a phrase used by Mr. Hoover and quoted approvingly by us. We explain the fallacy in his inference.

OUR contemporary at New York publishes a paragraph commending the mandatory circular issued by Minerals Separation and expressing the pious opinion that "the company has no idea of instituting vindictive methods with anyone who has used flotation without paying royalties for it." This statement is incorrect. The language used by Mr. John Ballot, the chairman of Minerals Separation, and by Dr. S. Gregory, its New York representative, indicates sentiments not to be reconciled with the ladylike policy thus outlined. On the contrary, the Minerals Separation people believe that they have a cinch and they intend to make the most of it; they expect to use the utmost power of the law in bringing infringers to their knees and compelling them to pay not only tribute, but ransom. The circular letter contained questions—such as those asking whether any flotation tests had been made on the ore and, "if so, by whom"—that have to be taken in connection with Minerals Separation's attempt to compel metallurgists to sign an agreement binding them not to disclose anything they learn in a mill or laboratory licensed by Minerals Separation to use froth-flotation. That contract was submitted by us to a good lawyer and he pronounced it

"without valuable consideration and unconscionable." There was no *quid pro quo*. It was a bluff, which failed, but it was one more evidence of the real policy of Minerals Separation, namely, to prevent the spread of knowledge concerning the process: to hold to itself not only the right to impose a royalty but the more objectionable power to place an embargo on technical information.

SPECULATION in cyanide is deprecated, we understand, by the one manufacturer of that product in the United States—the Roessler & Hasslacher Chemical Company—which has cut off the supply of several clients that took advantage of the scarcity to re-sell at a profit. The reason for this is obvious. If the price is advanced unduly there would be an inducement for other manufacturers to enter the field and so create unpleasant competition for the one now doing business. On the conclusion of the War the imports from Europe, invited by the high prices obtaining here, would then cause a collapse in quotations, but leave several manufacturers struggling to divide the trade. To this we must add that the Roessler & Hasslacher company has behaved well during the period of stress and their interest in this matter is not far from that of the present consumers. Nevertheless cyanide need not have been scarce had better prevision in the utilization of natural resources governed the selection of a site for new works. The Roessler & Hasslacher Company was fully prepared, by its contract with the Solvay Process Company for raw materials, to meet the normal demand in this country for sodium cyanide. The unfortunate reprisals between the United States and Canada did in fact provoke an embarrassing situation in regard to power. It is surprising, however, that so astute a firm as Roessler & Hasslacher should have resorted to Niagara Falls in the first instance, where power notoriously is not cheap today. Less expensive power undoubtedly could have been obtained at Portland, Maine, or even at Baltimore. Niagara has become recognized as a place for manufacturers to avoid, when cost of power is the controlling factor in their output. It is strange that the remarkable power-resources of the mountains fronting the Pacific Coast should have been overlooked in selecting a site for the manufacture of cyanide, the more so since practically all the consumers of this chemical are west of the longitude of Omaha. The majority of the water-power, developed and undeveloped, within the United States is found along the Pacific Coast, offering the most advantageous power-contracts in America. The problem of the relative freights on finished and unfinished products is accordingly the determining economic question in placing a plant. In this case it would have been wise to have considered the consumer. It is fair to him that a commodity such as sodium cyanide, used almost wholly in the far West, should also be made in the far West, saving cost in transportation of the raw materials that take a lower freight classification than the finished article, and giving security in the matter of adequate power at favorable prices.

Manganese in Brazil

Brazil possesses the greatest known iron deposits in the world. That fact is emphasized in an illuminating article by Mr. F. Lynwood Garrison, printed in this issue. Furthermore, Brazil is recognized as a great producer of manganese, ranking second only to Russia. Mr. Garrison has recently returned from an investigation of the manganese deposits of Minas Geraes, so that his contribution will be read with keen interest. The world is alive to the importance of manganese in these days when war calls insistently for steel. Every abandoned mine, every dump showing the glisten of psilomelane, is being searched and culled. The demand has even summoned the Pacific Coast into the field with its highly silicious manganese ores, which went begging before the War. The total domestic output of manganese ore was only 2785 long tons in the year 1914; California alone shipped 4013 tons in 1915, and an estimate from incomplete returns indicates a production in this State of nearly 15,000 tons last year. The fact that Californian buyers pay about 30 cents per unit for the manganese content, allowing a minimum of 16% silica in the ore, constitutes a measure of the present urgent need of this metal in the manufacture of steel. Mr. Garrison points out the remarkable purity of the Brazilian ores, which usually contain less than 6% of iron, with phosphorus and silica falling well within the Carnegie Steel Company's specifications, which govern in the American market. The manganese shipped from the state of Bahia, Brazil, seldom exceeds 4% in silica, 5% in iron, and 0.017% in phosphorus. The supply of high-grade Brazilian manganese, coupled with the increased shipments of acceptable ores from Cuba, has kept pace with the unprecedented use in this era of mammoth steel production.

If Brazil were blessed with coking-coal equally with her endowments in the other requisites for making iron and steel, she would develop into commanding industrial importance. Wanting in the third essential, a circumstance demonstrated by that distinguished American geologist, Mr. I. C. White, who examined the coal deposits of Rio Grande do Sul and Santa Catharina ten years or more ago, she seems destined to play the difficult political rôle that falls to any country possessed in notable abundance of some of the raw materials necessary to the progress and prowess of giant nations contending for supremacy. The greater ease with which the revolutionary outbreaks in Rio Grande do Sul and Santa Catharina have been controlled by the central government of Brazil during the last decade bears a striking relation to the crushing by Mr. White of any lingering hope that the industrial balance might be completed by fuel derived from these southern States.

The only coal resources that might possibly be brought cheaply to the Brazilian iron and manganese deposits from points geographically related to them, lie in the upper drainage-areas of the northern tributaries of the Amazon, west of its confluence with the Rio Negro, particularly in the watersheds of the Caquetá and Putamayo

rivers. A large trade is conducted today by Brazilian steamships between Manáos, the important central Amazonian metropolis, and the coast cities. Navigation extends far up the tributaries, uninterrupted by rapids until close to the Andean foothills and plateaus, where coal is everywhere to be found. These relationships may not be important at the moment, but they undoubtedly possess significance for the future.

Mr. Garrison finds in "the tendency on the part of South American governments to penalize industry" a deterrent upon enterprise. There is truth in this. Brazil has not yet entered into the game of protectionism, a game that can be carried too far. No country has played it in a quite scientific manner, and certainly none has solved the problems of equitable taxation. The fundamental principle applied in collecting revenue in Brazil, however, is based upon use and output. Unwisely applied it partakes of the nature of penalization, yet it contains the germ of an essentially just method of levying contribution upon industry for the support of government, harking back to the ancient customs that have colored nearly all highly developed Semitic systems of taxation in the history of the world. The Brazilians possess a well recognized legal talent, and their new code of laws, which has gone into effect this year, has met with high praise from foreign jurists.

Blue Sky Laws

A report made by Messrs. Horace J. Brown and Fred. M. Miller on a visit of inspection to sundry Arizonan mining districts has been issued by Mr. H. L. Carnahan, the Commissioner of Corporations in this State. His deputies went to Arizona in order to collect information concerning prospects that were being used as the basis of company promotions of a doubtful kind. Such promotions, worked by means of corporations organized in another State, are able, under cover of the inter-state regulations, to evade the Blue Sky law. This law, as our readers know, is one to control the peddling of shares under promises as limitless as the blue sky. Hence the popular name of the enactment. Similar laws have been passed in 26 States and when they have been adopted all over the country they will be even more effective than they are now. Michigan, Ohio, and South Dakota passed Blue Sky laws recently and we note with pleasure that they have been declared constitutional by the Supreme Court, which has decided that the individual States are empowered to deal with the question of fraudulent transactions within their own jurisdiction. The matter is important to those that wish to stimulate legitimate mining by rendering difficult the illegitimate phases of the business. Mr. Carnahan and his staff have done effective work to this end and it is our pleasure to support them so long as they show good judgment, as they have done.

Warning has been issued by the Commissioner of Corporations against the share-issues prompted by the high prices of metals. The big profits made by productive

mines have been used to incite the cupidity of the public and by aid of them a large number of wild-cats, or hopeless prospects, have been foisted upon the share-market. This State has been flooded with the so-called literature of the bucket-shops. It is well for the public to know that the Commissioner's function is to protect them by issuing certificates authorizing the sale in this State of reasonable stocks and by refusing his sanction to the worthless ones. Our own observation leads us to believe that the Commissioner is willing to give a mining venture the benefit of the doubt and that he places his embargo only on those that are thoroughly worthless. The intention is to encourage the organization of legitimate corporate ventures, not to check in any way the proper growth of sane prospecting or of reasonable speculation. Our people should realize this fact—perhaps they do. In any event as spokesman for our domestic mining activities we are glad to bring the matter to the friendly consideration of our readers, asking them to support this method of protecting the only kind of mining that is worth while. Every dollar that gets into the clutches of the unscrupulous peddler of wild-cat shares is a dollar lost to useful development and intelligent exploration. Of course, the Commissioner cannot give the hall-mark of success to any venture; his certificate is not a guarantee, but it does indicate that the subscriber to the stock will have a run for his money: the broker's profit is limited within reason, the promoter is compelled to use legitimately a proper proportion of the money he collects, so that the cash contributed by subscribers is expended in mining and not in filling the pockets of shady adventurers. Some of the stock peddled in California has been offered with the assurance that it had been authorized by the Corporation Commission of Arizona, but it is well that speculators should know that the Arizonan Blue Sky law is different from our own and even if it affords some measure of protection to citizens of Arizona it affords none to those of California. It appears that one of the stocks peddled in this State recently has been the Arizona Ray Copper Company, to which we referred incidentally in an editorial commenting upon the attempt to persuade Arizonan school-teachers that they could become rich quickly. Mr. Brown made a careful enquiry and obtained sufficient trustworthy information to brand as "outright falsehoods" most of the statements made by the promoters of the Arizona Ray. Instead of being "a marvelous bonanza" this is a group of 12 claims discarded as worthless by the Ray Consolidated Copper Company. The claims were considered, by competent men, to cover ground outside the ore-zone, which had been delimited by careful drilling. Experienced engineers advised that "these claims were not worth prospecting, holding, or patenting." Yet this discard has been advertised as "a sure winner, certain to develop into a great copper mine." As Mr. Brown says, it is possible that even such an apparently hopeless piece of ground might be found to enclose a valuable orebody, but, in face of the unanimous opinion of competent judges, it is extremely unlikely. There

may be such things as volant, non-ruminating, artiodactyles but the proverb declares them to be "very unlikely birds." In any event, the practical view of the matter is that when ground has been adjudged worthless by competent inspection it cannot be declared rich except by the actual production of ore. One of the most insidious misrepresentations has been the statement that Mr. E. L. Hiatt resigned from the service of the Ray Consolidated "to accept the mine management of Arizona Ray." He left that company's employ six months previously on account of ill health. He obtained 337,500 shares of stock for a one-fourth interest in the 12 claims and \$12,500 in real money. Although he became engineer to the new company at a salary of \$5000 per year, he has resigned his connection with it, and the fact has been disclosed that he had an agreement with the brokers whereby his name should not be used in connection with the advertising or sale of stock. Another easy way to give verisimilitude to a series of otherwise unconvincing yarns was to turn a broker's assistant into a 'mining expert,' which being done he stated confidently that the Arizona Ray "should contain between 30,000,000 and 40,000,000 tons of ore." An advertised statement that the listed shares were 'treasury' shares was made, evidently to create the impression that the mine was getting the benefit of the capital thus obtained, whereas the fact was that every advance in the selling price meant more profit to the broker but not more working capital for the venture. The finding of some low-grade copper ore by a drill-hole was used to announce "a big copper strike" and the addition of "a third big copper mine to the district." One broker advertised his prediction that the stock would sell at 50 cents "when the ore is struck" and he offered to back his statement with his "own private fortune." If he corrects the difference between the present price of Arizona Ray and 50 cents, he will have made a large hole, as Mr. Brown suggests, in a very considerable fortune. But it is not worth while further to castigate this predatory scheme. Let us add, however, that this hopeless prospect is capitalized for \$1,000,000 in 10,000,000 shares, of which 5,000,000 went to the promoters. When treasury stock was being offered as a bargain at 30 cents—three times the par value—it happened that less than 4 cents per share in money and less than 3 cents per share in notes had been paid by the promoters to the company for this stock. This is a good example of real 'wild-catting,' a euphemism that is used much as 'high-grading' is employed as a synonym for 'ore-stealing.' Many other share-peddling schemes of a sinister kind have been perpetrated all over the Southwest and a great deal of money has been raised, to be lost, from among people of small means. The Jerome district is the incubator of a big litter of young wild-cats—otherwise 'frauds.' Let us hope that the Californian bear will continue to make it dangerous for them to invade this State, and may we not also entertain the hope that the State of Arizona will awaken to the dishonor that is being done to her splendid mining industry by such antics.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Flotation of Gold Ores

The Editor:

Sir—I should like to offer some comments on the article 'Metallurgical Problems of the Rand' by Mr. H. Foster Bain, appearing in your issue of February 17.

In his discussion on concentration Mr. Bain brings out some interesting points and suggestions among which, however, there are one or two that do not coincide with the experience of metallurgists in this country. Speaking of flotation he says, "the objection to ordinary wet concentration would apply equally in the case of flotation, and would even be stronger since the air-bubbles are not known to have any affinity for gold." The reason advanced for the failure of wet concentration is "the simple fact that the gold occurs not only in the pyrite but in the quartz."

In my opinion the latter statement would not necessarily predicate the failure of flotation, because for the past two years or more it has been known among metallurgists engaged on flotation work that free gold can be recovered from its ore by flotation when reduced to the right degree of comminution. In confirmation of this statement the following results of actual tests may prove of interest.

The ore on which the tests were made was from a mine in the Grass Valley district, California, and resembled in some respects the Rand ores, the gold occurring both in the pyrite and quartz. The first test was made on an average sample of the ore as delivered to the mill, which for the purpose of the test was crushed to pass 100-mesh screen, then treated by flotation. For the second test an average sample of plate-tailing from the same mill was crushed to pass 80-mesh, and treated by the same process.

TEST NO. 1. MILL HEADING

	Weight, %	Assay gold, oz.	Recovery gold, %
Heading	100.00	0.316	100.00
Concentrate	3.08	9.98	97.00
Tailing	96.90	0.01	3.00

TEST NO. 2. PLATE-TAILING

	Weight, %	Assay gold, oz.	Recovery gold, %
Heading	100.00	0.12	100.00
Concentrate	3.31	3.33	90.20
Tailing	96.68	0.01	9.70

The plate-tailing sample when crushed to pass 200-mesh yielded a recovery of 95.98% in a concentrate assaying 3.56 oz. per ton and a tailing assaying 0.005 oz. gold per ton.

Another series of tests, equally as interesting, since they give comparative figures of recoveries obtained first

by amalgamation, second by cyanidation, and third by flotation, was made on a gold ore from Nevada. The ore was an ideal one for cyanidation, while it was not considered suitable for flotation because it contained a highly colloidal constituent and further the gold was present in the free state with only a minute amount of sulphides. The assay-value of the raw ore was 1.15 oz. gold. Amalgamation on a sample of the material crushed to 30-mesh yielded a recovery of 49%. The recovery shown is undoubtedly low for a free-milling ore but the cyanide-tests indicated unmistakably that the gold was finely disseminated throughout the quartz and was not completely liberated until crushed to pass 200-mesh.

A second sample of the ore was crushed to 200-mesh and then treated by cyanidation, giving the following recovery:

	Gold, oz.
Heading	1.15
Final residue	0.015
Recovery	98.60%

Time of agitation, six hours. Strength of solution, 0.075% KCN. Total cyanide consumption, 1 lb. per ton of ore.

For the flotation experiments a third sample of the material was crushed to 100-mesh, then treated by ordinary flotation using 1 lb. of oil-mixture per ton of ore in a neutral circuit with a pulp-density of four parts of water to one of ore by weight.

	Weight %	Assay oz.	Recovery %
Heading	100.00	1.15	100.00
Concentrate	1.35	71.40	81.60
Tailing	98.65	0.22	19.30

The first assay shown above is the head value calculated from the sum of the products multiplied by its assay. The recovery is based on this figure.

When the ore was crushed to pass 200-mesh and treated by flotation it yielded 92.2% of the gold in a concentrate assaying 33.78 oz. and a final tailing assaying 0.10 oz.

The above tests were selected for the reasons that in the first instance the ore tested was of the same general character as the Rand ore, the gold occurring both in the pyrite and quartz; in the second instance the gold occurred almost entirely in the free state.

In the light of the results obtained by treating these ores by flotation it would seem well worth while to give the same principles a trial on Rand ore since the objections raised by Mr. Bain appear to be unfounded.

With Mr. Bain's suggestion to produce a small propor-

tion of high-grade concentrate, I am in agreement. But I am inclined to think that if flotation could be successfully applied to the recovery of pyrite from the tailing, it would be equally successful in extracting the pyrite from the original ore, and if the ore were crushed fine enough to free not only the pyrite but also the gold locked up in the quartz, it is possible that the whole of the flotation-tailing could be rejected as was shown to be possible in the tests on the Grass Valley ore. The resulting concentrate being comparatively small in amount, could profitably be ground to any degree of fineness found necessary for extracting practically the whole of the gold by cyanidation.

In the event of flotation failing to give a tailing low enough to be discarded, a useful line of investigation would be first to amalgamate on plates, re-grind the plate-tailing to a point at which the pyrite is liberated, treat the re-ground pulp by flotation to recover the pyrite, thicken and filter the flotation tailing and then subject it to cyanidation.

It can be safely stated that flotation is not in any way injurious to a subsequent treatment of the tailing by cyanide. In several instances flotation, used in place of tabling, ahead of cyanidation, has not only materially increased the extraction of noble metals but has also decreased the cyanide consumption as much as one pound per ton of ore as compared with the amount used, when tabling was employed, the reason advanced for this being that elements deleterious to cyanide were removed by flotation and not by tabling.

The present high recoveries prevailing on the Rand leave little room for improvement in this respect, but there does appear to be some scope to simplify the treatment and reduce the cost of operation by making the plant more compact. The above suggestions offer a likely means to this end.

F. A. BEAUCHAMP.

San Francisco, February 23.

Kathleen Consolidated

The Editor:

Sir—On or about December 26 there appeared in the daily press an article advertising very highly the mining property of the Kathleen Consolidated Mining Company of Willard and Estancia, N. M., with mines at Scholls switch, N. M. The property was represented as adjoining the \$1,000,000 property owned by Col. Pritchett and Tex. Craven [both names misspelled]. Mr. French, the State Engineer, certain "Phelps-Dodge mining experts" and "State Geologist Kirk" are quoted as saying the ground "is rich in copper and silver [italics mine]."

Mr. French does not pretend to be a mining man. The Phelps-Dodge men could have given the ground only a casual inspection when there, for it was practically unprospected at that time. I have been along what I am told is one edge of it, but have not seen an identifiable marking or corner. My examination of a near-by prop-

erty gave me the opinion that the Pritchard-Cavin ore-body, as mined at the time of my visit, does not trend toward where I am told the Kathleen claims lie. The district is known to carry no appreciable value in silver.

Briefly, the whole matter appears so glibly and questionably handled that in spite of the good names of Willard and Estancia bankers connected with it, I am disposed to discredit it as looking suspiciously like the old-fashioned species of wildecating which we all hoped had long ago left the New Mexico diggings. A month of correspondence has failed to get me the opportunity to confirm the statements attributed to me and to others quoted. I have watched for the report upon this ground by any engineer or geologist, but have not seen any nor been advised of such.

Just as in any other mining district, there are barren spots in this (Carecito) district, and I would protect honest investors by holding out in this and similar cases against investment without reputable advice. I consider the above action as part of the duties of my office.

CHARLES T. KIRK, State Geologist.

Albuquerque, N. M., February 23.

Fine Grinding at Inspiration

The Editor:

Sir—Referring to the further discussion, by Mr. David Cole, of the above subject, in your issue of February 17, I am of the opinion that you, Sir, and the mining public would not be interested in any discussion that is misleading, though doubtless not so intended.

Mr. Cole is mistaken both as to the mill and the test referred to by me. I had not supposed that a combination of cemented pebble lining and manganoid balls would be taken seriously, although the experiment he mentions was undoubtedly tried. The only way that I can explain Mr. Cole's undoubted ignorance of facts, is, that he could not have investigated the matter after the "pebble lining and manganoid ball experiment," and I shall call attention to discrepancies in his statements that show this to be so. Instead of Mr. Cole saying an 8 ft. by 36-in. Hardinge mill, he should have said that in the trials an 8 ft. by 44-in. was used; instead of the mill being direct-connected to a 75-hp. motor, it was belted to a 150-hp. motor. He should have said different types of feeders were used; cast-iron liners were used; steel balls were used; and two drag classifiers were used. There are also other discrepancies in Mr. Cole's statements that I shall not take space to correct now.

It is my opinion that in competitions of crushing or concentration machinery where one set is arranged tandem and the other side by side, no matter what the results show, an element of uncertainty is introduced, and it cannot be proved that a change in arrangement might not have brought about a change in results.

As to the word 'competition,' which Mr. Cole used in his letter of December 9, 1916, and I used later on the same subject, he knows best what he meant. I appreciate that the tests with Hardinge mills may not have been

conclusive and perhaps not satisfactory to all or to the manufacturer. I am not particularly interested in these tests, but I do think that one should be careful in all technical discussion regarding detailed statements and particularly as to their correctness. If this is not done the public who read are misled.

In conclusion, I call Mr. Cole's attention again to the fact that the results of tests between the cylindrical tube-mill and four pebble-mills at Inspiration have not been published. I suggest he do this while we are waiting for "the experiments now approaching the period of fruition." This is for the interest of the mining public who "love truth and fair play."

Salt Lake City, February 19. C. T. VAN WINKLE.

Ball-Mills

The Editor:

Sir—In answer to a question raised by A. E. Drucker in your issue of February 10, I am able to state from experience that the chief argument against the Krupp wet ball-mill is something of a more permanent character than that "Essen is blockaded," namely, the high cost of maintenance and repairs. By 'Essen,' Mr. Editor, I presume you mean Krupp's mining-machinery factory, which is at Magdeburg, a city devoted to peaceful industry and situated less than two hours by rail from Berlin.

Two classes of ball-mill are made by Krupp, for wet and dry work respectively, and differing but slightly from each other in mechanical design. Having operated both, I am able to make a comparison of their relative efficiency.

The dry machine is highly efficient because of the facility with which it screens and discharges the desired product, a matter which I discussed at some length in a paper on 'Dry Crushing and Roasting at Kalgoorlie, Western Australia,' published by the Institution of Mining and Metallurgy, London, in 1903. The screens form the revolving cylindrical body of the mill, have a comparatively large area, and are graded in decreasing size of mesh from that of being mere holes in the interior cylinder of buckle-plates on which the actual crushing is done, to that of the fine wire-mesh encircling the perimeter through which the finished product is discharged.

In action the oversize particles, before being returned to the centre of the mill for further crushing, perform the function of scouring, cleansing, and vibrating the screens in a manner precisely similar to that of the metallic disc, used by most assayers, on laboratory-sieves, to assist in rubbing through the meshes such particles of pulverized ore as are of the desired fineness in the assay-sample under examination.

With wet pulp, screen classification is infinitely more rapid than with dry material. The undersize is quickly discharged, and what then happens is that the wet angular fragments of oversize in motion on the screen develop a highly abrasive action on all metal with which

they come in contact. The wear, therefore, becomes excessive and this is precisely what is found with the Krupp wet ball-mill. Its screen-area is large and consequently, as this is subjected to the greatest amount of destructive attrition, much running-time and money are lost in effecting renewals and repairs. I question if any engineer can be found to recommend such a machine after having experienced the difficulties of its operation. I know of one mining company in Ontario that, having installed a 'wet' Krupp mill and found it unsuitable for the purpose intended, solved the problem by selling it to a neighboring property. By the new owners it was re-constructed and operated for a purpose in which dry crushing was essential, and in this capacity it was thoroughly satisfactory.

At Broken Hill, Australia, in 1906, Krupp wet ball-mills were used extensively for crushing lead and zinc ore to a mesh suitable for table-concentration and flotation work, but, after exhaustive trials, they were discarded in favor of tube-mills. This has been the experience of all other localities of which I have any information. As a competitor against, say, the Marcy or similar mills I can assert that the Krupp machine is not in the running.

Cobalt, February 17.

W. E. SIMPSON.

Manganese in California

The Editor:

Sir—Garnett A. Joslin's article on 'Manganese in West-Central Arkansas' in your issue of December 30, brings to mind the similar occurrence of manganese in California. It is an interesting fact that most of the manganese deposits in the United States are in rocks of marine origin and appear to be genetically related to the deposits in which they are found. A discussion of the origin of these deposits should throw some light on the subject.

Numerous deposits of manganese ore occur in the Coast Range in the Franciscan formation, which comprises a thick series of sandstone, shale, and chert. It is in the chert that all the manganese of commercial importance has been found. The chert has characteristics similar to the 'novaculite' of Arkansas, as described by Mr. Joslin, being hard, flint-like, and very fine-textured. The prevailing color is dark red, but there are also green, yellow, black, brown, gray, and white varieties. Usually remains of radiolaria can be seen throughout the chert, in some places in abundance. These beds of chert are from 1 to 4 inches thick, separated by partings of shale $\frac{1}{4}$ to 2 in. thick. The beds of shale and chert alternate with remarkable uniformity, and as a whole, have been much twisted and folded, with many overthrust anticlines, and much dove-tailing.

The deposits of manganese are wholly within the chert along zones parallel to the strike of the beds. The deposits are elliptical or lenticular in shape, varying in size from a few feet to 75 ft. long, and from 1 to 15 ft. wide. The ore is composed of the oxides of manganese,

principally pyrolusite, psilomelane, and ochreous wad. In many of the deposits a high content of silica is present. The deposits have a pitch in the general direction of the dip of the chert, with the longer axis parallel to the strike of the beds.

As the manganese deposits are associated with the chert only, it might be assumed that this is the source of the ore, and that the origin of the manganese is connected with that of the chert. The presence of radiolaria at once suggests a deep marine origin, but the associated shale seems to disprove this theory. Andrew C. Lawson, of the University of California, suggests that the silica might have come from silicious springs on the ocean-floor, the silica being in a colloidal form, or ooze, the remains of radiolaria having become imbedded in the silica. The partings of shale are due to the fact that at various times there was an influx of sediment into the sea, during periods of flood, when the streams are heavily charged with the products of erosion. The rate of deposition of the silica would not be affected by this, but the silica would be disseminated throughout the sediment, and a deposit, rich in silica, would be the result. E. F. Davis, of the University of California, found remains of radiolaria in the shale also, and an analysis showed it to be high in silica.

If the hypothesis that the chert is of marine origin be accepted, it is easy to account for the manganese oxide. Manganese hydrates, with ferric hydrates, are widely distributed in marine deposits, especially in abysmal regions, where they occur as a coating, or as nodules. During the expedition of the *Challenger* in 1878, the trawl brought up great quantities of manganese nodules from nearly all depths below 2000 fathoms. Many specimens of chocolate clay (colored by manganese) were obtained in the Pacific and Indian oceans, and objects such as rocks, coral branches, and shark's teeth were coated with a black dendritic manganese oxide.

The source of the manganese is supposed to be in the basic volcanic rocks and minerals with which the nodules are associated in deep-sea deposits. The manganese of these rocks is transformed first into carbonate and subsequently into oxides, which, on deposition in the ooze, take a concretionary form around various nuclei. So, it can be seen that in deep-sea deposits manganese may occur sparingly throughout the chert, or it may, by accretion, in places, form large masses.

Analyses of the chert by Mr. Davis showed that the main constituents were iron oxide and silica, and that it contained about 1% of manganese oxide. Veinlets can be seen in the chert in many localities, and it is common to find stains of manganese oxide on the chert remote from a deposit of the ore. Analyses, microscopic examinations, and the presence of coatings of manganese oxides on the chert indicate that the oxide is sparsely disseminated throughout the beds. The workable deposits are secondary concentrations, and in some of the deposits the manganese replaces the chert, the original structure of the beds being perfectly retained.

Little development work has been done on these de-

posits as a whole, and their extent in depth has not been determined.

DON CARLOS BILLICK.

Latouche, Alaska, January 27.

Belgian Relief

The Editor:

Sir—In your issue of February 17 an editorial appeared under the heading of 'Belgian Relief.' In it you quote Mr. Hoover, as follows: "The man who is swayed by his emotions is usually a man of small intellect, *and the man of small intellect is always a man of small pocket-book*" (the italics are mine). Then the Editor adds: "With that we agree; emotional excitement will not help the little ones in Belgium."

Now, Mr. Editor, did you really mean that, or were you and Mr. Hoover joking? The man of small intellect is *always* a man of small pocket-book"? Wow! That chunk hit me right between the eyes, for I am a man of small pocket-book, and therefore —!!! As I have a few poor relations, I have only one share of Belgian Kiddies, Ltd., pinned up on my wall, and I know of several of the greatest men in the history of the world, names that will live, that were men of small pocket-book. I looked carefully in the following issue of the *PRESS* to see if someone of larger intellect than mine had not noted the hole that a great engineer and a great editor had stepped into together, and commented thereon.

Dear Mr. Editor, please tell me that you two boys did not mean it, for I do not wish to place those whom I have held in such high esteem in the same category with Edison on Religion, Ford on Peace, and Roosevelt on Pre-Election Promises.

J. D. HUBBARD.

Paradise, California, February 25.

[Our friend has made an illogical inference. He errs in assuming that one "all," or "always," includes the other. We did not say that all men of small pocket-book are men of small intellect. The fallacy will appear by applying the syllogistic method. Letting *A* equal all men of small intellect; *a* equal some men of small intellect; *B* and *b* respectively all and some men of large intellect; *C* and *c* respectively all and some men of small pocket-book. We have affirmed that $A = c$. Our correspondent has affirmed $C = A + b$, which is a quite different proposition from the unfortunate but not unreasonable state expressed by $b = c$. To this we shall add our regret to have seemed to say anything unkind concerning men of small pocket-books, to whom we and most of our friends belong.—EDITOR.]

FROM ALL QUARTERS complaints are made that contracts entered into for the supply of molybdenite have been very imperfectly fulfilled. In addition to some scarcity of the ore, the freight congestion has played havoc with the market and on account of the inability to obtain raw material in quantities, it is impossible now to secure from any quarter a quotation on ferro-molybdenum for reasonable delivery.

The Mining Industry of Brazil

By F. Lynwood Garrison

INTRODUCTION. In its early history, that is to say, about the years 1700 to 1820, Brazil was one of the important mining countries of the world. It is estimated to have produced within that period as much as thirty million ounces of gold and it is believed that there was exported clandestinely from one-fifth to one-half as much more.

The governmental tax exactions in the early days were undoubtedly onerous, being at one time as much as 20% of the gross output. Various schemes for exacting tribute were tried from time to time, despite protest, but the spirit of the Government has not changed even to this day, although a more liberal view of such matters has been shown at times. The tendency of nearly all South American governments to add tax on tax upon mining industries is short-sighted, a mistaken policy to which may be attributed much of the present backwardness of these countries. Revolutions are bad enough, but heavy and unfair taxation is fatal.

The mining industry made a good start in Brazil, but now, although this country has an area as large as the United States, its mines are few and contribute little to the general wealth of the world. Outside the State of Minas Geraes it may be said that mining in a modern sense does not exist and in that State there are but two gold mines and perhaps a half-dozen manganese properties which are in active production.

It is my purpose to discuss a few facts regarding the mineral resources of Brazil that are known to many mining engineers and economic geologists, but about which the general public is profoundly ignorant.

IRON. The extent and value of the iron deposits in Minas Geraes was first authoritatively pointed out by Orville A. Derby in a communication read before the eleventh Geological Congress held at Stockholm in the year 1910. Dr. Derby said: "Practical iron men and geologists who have visited the various parts of the district hesitate to pronounce impossible estimates that at first sight seem utterly preposterous. Henri Gorceix, founder and for many years director of the Mining School at Ouro Preto, who has a very intimate knowledge of the district, stated in a public lecture in 1881 'I have estimated at five billion tons the iron ore that Minas Geraes might furnish and I fancy that I should not be exaggerating if I were to double this estimate.'"

A careful reading of the text of this communication as printed in the official publications of the Congress and entitled 'Iron Ore Resources of the World,' Vol. II, p. 819, does not show that Derby confirms this statement directly, but he does so by implication and further quotes from a private letter of R. A. F. Penrose in which Mr. Penrose gives credibility to these estimates, which are so

enormous it is important to make clear the responsibility and reliability of those who made them. Derby, it may be said, was, at the time of his death two or three years ago, the highest authority on Brazilian geology and Penrose had himself visited many of these iron ore deposits, so he must have been in a position to form some definite conception of their importance; moreover, being an able mining geologist, his views will carry weight in the United States.

Derby further stated that many years ago he had observed an identical ore formation at various points along

BORROWED FROM *Economic Geology*.

the Sao Francisco river and although his examination was but cursory, it seemed possible these iron deposits may be comparable as to quality and quantity with those of Minas Geraes.¹

The Minas Geraes ore is predominately hematite—hard, dense and specular—having, according to Harder, the following composition:

	%
Iron	69.65
Phosphorus	0.0125
Silica	0.24
Combined water	0.38

There is, of course, much ore inferior to this, but even the poorest (*canga*) ranges between 50-65% iron and 0.1-0.3% phosphorus. On page 153 Harder gives a table of average analyses of iron and phosphorus for the different grades of ore.²

It is not my present purpose to expatiate upon this economic fact, save to add that its importance has been recognized and large areas of these iron-ore lands have passed into American control. Moreover, the British

¹Trans. A. I. M. E., Vol. L, page 143.

²*Ibid.*, p. 822.

company operating the old and famous St. John del Rey gold mine has also acquired large holdings in the neighborhood of this mine with the view to producing iron ore when a favorable market has been established.

The geology of the Minas Geraes, or Itabira, iron formation has not been worked out; the German geologist Gathmann attempted to prove the ores to be only secondary residual, and surficial formed by the leaching of the silica from an iron-bearing quartzite for which the term 'itabirite' has been adopted.³

In *Economic Geology* of March 1914 Harder⁴ answers this criticism and observes: "The question, as to whether the iron ores of Minas Geraes are the result of original deposition or of surface concentration, is one of great practical importance. If the ores are the result of surface-weathering agencies, then they cannot be expected to go to any great depth, except perhaps along important water-channels such as have been found to occur in some of the deposits of the Lake Superior district. If, on the other hand, they are the result of original deposition, then the depth to which they might continue is indefinite, and the changes to be expected are only such as would result from processes affecting original sedimentation. *The facts seem to me clearly to prove the latter view.*" Harder is a mining geologist who has made a special study of the Brazilian iron-ore deposits as compared with those of the Lake Superior region. The above italics are mine because I wish to emphasize an opinion that ought to carry great weight.

It would seem, therefore, if these views and opinions are worth anything, that it will be only a question of a comparatively short time before a large iron-ore mining and shipping industry is established in Brazil. At present heavy shipments cannot be made because the existing railways were not designed for such traffic and there are no proper storage and shipping facilities at Rio de Janeiro and Victoria, the two seaports through which this traffic would have to go.

The Central railway, owned by the Government, which runs from Rio de Janeiro through the heart of the mining districts of Minas Geraes, is now handling a large tonnage of manganese ores at a price to the shipper of something like \$1.25 to \$1.50 per ton for an average haul of 300 miles.

When we consider that the ton-mile cost of operating the Brazilian railways is 7.04c., the highest of any system in the world, this rate must be considered low.⁵ Nevertheless it would probably be necessary to build an entirely new railway system for handling the enormous tonnage that a great iron-ore mining operation would require or else re-construct the old railways, for as they are now there is scarcely a tangent in any of them where it has been possible to put a curve.

MANGANESE mining in Brazil was commenced in the state of Minas Geraes about the year 1893 at a place called Miguel Burnier on the Central railway. The in-

dustry developed slowly and has been carried on intermittently for a number of years; when exchange was low, that is when the milreis was worth from 20 to 25 cents, it flourished, but higher rates without a corresponding decrease in wages seriously curtailed the output.

With the outbreak of the Great War and the complete cessation of manganese shipments from the Caucasus, the Brazilian production has increased rapidly; moreover, new and larger deposits have been opened up in the Lafayette or Queluz district, so today the Morro da Mina is not only the most important one in that region but is probably the largest manganese mine in the world, and curiously enough this property some ten or fifteen years ago in its then partly developed condition, was considered almost worthless, a circumstance attributable to the lack of knowledge concerning the geology of the region in general and of the genesis of the deposits in particular.

Brazil is now producing more manganese than ever before, the prices are high, the profits large, and were the handling and shipping facilities at Rio de Janeiro what they ought to be, the returns to the miner would be enormous. The Morro da Mina mine is owned and operated by Brazilians; the Cocuruto, the next largest, has an English manager and is controlled by Belgian interests. Practically all the manganese ore produced in Brazil is sent to the United States; England and France obtain their supplies from India.

The quality of the Brazilian manganese is distinctly good, averaging between 45 and 50% metallic manganese; the phosphorus and silica contents are low, with only 5 to 6% of iron.

Manganese ores are rather common throughout Minas Geraes and Bahia but they have not been sought systematically except in the former State and even there the area thus far known and developed is relatively small.

GOLD. There are at present but two going gold mines in the whole of Brazil, the famous old St. John del Rey and the Passagem. The former produces about \$2,000,000 and the latter some \$500,000 of gold per year.

The St. John del Rey is one of the classic mines of the world and has been in operation continuously since 1830. It was first opened in 1725 and was supposed to be exhausted at the end of that century. It also has the distinction of being the deepest mine in the world, having by now probably reached a depth of over 6500 ft. vertical. Notwithstanding the large production of these two properties, their methods of milling are not up to date. This is not any reflection on the management, which, judging from what one hears in Brazil, must be, all things considered, excellent.

The geology of the gold region in central Minas Geraes has been studied by Derby, Branner, Scott, and others. It is not my present purpose to more than refer to it. There seems to be no doubt that many of the gneisses and granites of this region contain appreciable quantities of gold, hence the alluvial deposits were rich in the early days and the source of much if not most of the

³*Zeitschrift für Praktische Geologie*, XXI, May, 1913.

⁵The ton-mile rate in the United States is 0.729c.; in France, 1.18; in Germany, 1.24.

\$600,000,000 worth of gold produced by Brazil in the early days of its settlement.

Readily accessible placers have all been pretty well exhausted by the native washings, but no doubt there are many opportunities where modern hydraulic and dredging methods can be applied successfully just as was the case in California after the exhaustion of the easily worked stream and bench gravels. The present seems an interim period in Brazil between the primitive methods of the past and the modern washing systems of a mechanical age.

The quartz-gold deposits in Minas Geraes and Bahia are uniformly low-grade, not to say lean, and this condition has been a great drawback to the development of lode mining. There have been some rich discoveries, like the Gongo Socco, where the auriferous jacutinga was found to be composed in great part of laminated masses of gold weighing from a few grams to several kilos.⁶ Two-thirds of the gold extracted from this mine was in masses, plates, and threads of native metal, and one-third was disseminated through the adjoining matrix, but as is always the case in such rich treasure-trove, the extent and volume is limited and experienced mining men always regard such mines with suspicion.

DIAMONDS were discovered in Brazil in the second half of the 18th century and the recovery of them from stream gravels by simple washing methods continued with more or less success until the discovery of the South African deposits in 1871. Although Brazilian diamonds are said to be the best in the world, being harder and of better color than any others, there is not today in Brazil any properly organized and equipped diamond-mining industry. The small amount of Brazilian diamonds that reaches this market and that of Europe is derived from alluvial washings in which a wooden bowl and an iron scraper is all the equipment required by the native.

All diamonds in Brazil are the property of the Federal Government from which the miner must lease or obtain a concession. Such grants, however, are easy to obtain and it is only after the operator begins to make money that the Government is likely to make trouble for him.

The geologic conditions governing the occurrence of diamonds in Brazil have not been worked out, although a number of articles have been published on the subject. It seems the gems are found somewhat sporadically in the alluvial debris of the sedimentary rocks—sandstones and conglomerates—but they probably had their origin elsewhere. Occasionally the diamonds are found embedded in these sedimentary rocks, evidently having been part and parcel of the ancient sediments and detritus of which they are composed.

According to Derby, there are enormous areas of such diamond-bearing rocks in what is known as the Lavras region of Bahia, but only a relatively small part of this area can be worked with profit by the processes now in vogue in the country. This distinguished geologist believed that with the use of proper engineering methods and the abundant water-power the region affords, an ef-

fective solution of the problem may be found, but that it is one for the engineer rather than the geologist—in short, the probabilities of a successful outcome are strong enough to justify serious study and experiment.⁷ It is certain that the present Brazilian diamond-mining practice cannot compete with the well-equipped and technically directed South African mines.

A characteristic of the Brazilian diamond deposits, especially in Bahia, is the frequent occurrence of the black, gray, or brown material known as *carbonado*, which is an amorphous form of diamond used in drilling.

In Bahia rough diamonds are prepared for the market in a curious way. Stones with flaws or a rough skin are

PART OF BRAZIL, SHOWING MANGANESE DEPOSITS.

- (1) Bahia; (2) Miguel Burnier-Ouro Preto; (3) Lafayette; (4) Corumba.

charged into a crucible and heated at a cherry-red temperature for three or four minutes, then the crucible is removed from its charcoal bed, a tablespoonful of potassium nitrate is thrown over the stones and the crucible well shaken. As soon as the fume has gone off, the diamonds are taken out, washed, and counted; it is usually found they have lost about 8% in weight, but doubled in value. Just what happens during this process, I have not heard explained, but evidently some of the carbon of the skin or surface of the stones has been burnt out or oxidized.

The genesis of the Brazilian diamond deposits has long been a geologic puzzle. As previously mentioned, in Bahia the diamonds are found associated with the debris of certain sandstones and conglomerates and actually in the rock itself. It seems highly improbable they had their origin in these sedimentary rocks, but more than likely they entered into the mechanical composition of the sandstones and conglomerate beds like any other pebble. It is true, in certain localities, as at Sao Joao da Chapada, 12 miles west of Diamantina, in Minas Geraes, diamonds have been found in quartz veins that accompany a rock of unknown character containing plates of specular iron, tourmaline, and pyrite. In the Diamantina region, the diamond occurs *in situ* in its original matrix in fairly well-defined veins.⁸

⁷Economic Geology, Vol. I, page 140.

⁸Derby, *Am. Jour. Sci.*, Vol. XXIV (1882), p. 42.

⁶H. K. Scott, *Trans. A. I. M. E.*, Vol. XXXIII, p. 418.

According to Branner, the diamonds of Bahia are found in what is known as the Lavras series of quartzites, which are probably of Carboniferous age. Dr. Branner speaks of this sedimentary series as the immediate source of the diamonds and seems to lean toward the belief they also had their origin therein.⁹ While it would be presumptuous for me to question the view of one so much better qualified, I cannot see any good reason for not assuming that the diamonds originated in the primal peridotites and dunites of the neighboring granitic and gneissic areas. It is certain these rocks are now associated with serpentines, which, as is well known, are derivatives of ultra-basic rocks, like peridotite.

OTHER MINERALS. There are great areas of old crystalline rocks in the large States of Minas Geraes and Bahia with which are intimately associated important deposits of iron, manganese, chrome, gold, mica, copper, and, as we have seen, perhaps also the diamonds. The iron, manganese, and chrome may be made of immediate commercial value because they exist in large quantity and can be mined and shipped without previous preparation or treatment of any kind.

The present outlook for gold mining in Brazil is not hopeful; on the whole its history has been disappointing.

Attempts have been made to mine mica and monazite sand from the unquestionably large and valuable deposits of these minerals in the State of Bahia, but for one reason or another they have been discontinued. In Minas Geraes the mica industry seemed promising at one time and an interesting paper was written upon the subject by H. Kilburn Scott.¹⁰

Of copper very little is known, although it has undoubtedly been found in a number of localities. I was shown some samples of excellent ore said to have come from near the Jaguarary railway station in the north-eastern corner of the State of Bahia. It is the locality mentioned by Branner in his article published in the *Engineering & Mining Journal* of May 22, 1909. These copper deposits have never been seriously prospected and are, I understand, quite a long distance from the railway.

During the years 1904-1906, the Brazilian government employed I. C. White, of West Virginia, to make an examination of the coal deposits known to exist in the States of Rio Grande do Sul and Santa Catharina with the view to their economic development. Numerous borings were made, some of them as deep as 1000 ft., and several seams of coal were cut ranging in thickness up to seven and eight feet, but all of very inferior quality. Some of this coal is said to have been mined and sold, but in its raw state it was unsuitable for commercial purposes and could be made saleable in competition with imported coal only after having been washed, cleaned, and made into briquettes.¹¹

So far as known, coal has not been discovered in any

other part of Brazil and as by far the greater part of this vast country lies well within the tropics, it is unlikely that any considerable amount of good coal ever will be, since, for some never-satisfactorily explained reason, coal fit for steam or commercial purposes is exceedingly rare in tropical countries.

The future development of metallurgical industry in Brazil will evidently have to depend upon a supply of hydro-electric power for smelting purposes, or else the use of expensive imported coal. Fortunately there are plenty of water-power sites in many parts of this enormous country, especially in Minas Geraes and Bahia, where power is most likely to be wanted and where the more important metalliferous deposits have so far been found.

It cannot be expected, however, that such highly technical industries are likely to be initiated and financed by the Brazilians themselves unaided by foreigners, because the natives lack not only the technical skill but also confidence in themselves to carry out the work to completion, which is the logical corollary to inexperience in such matters. Moreover, there is always a haunting dread of governmental interference and excessive taxation once an industry becomes profitable.

This undoubted tendency on the part of South American governments to penalize industry comes from ignorance of sound economic principles on the part of the educated and governing classes. In South America there is no such thing as public opinion, as we understand it, for most of these countries are ruled by an oligarchy composed of a few hundred families. No one knowing South America will question that this is probably the best system of government that can be maintained, provided always the governing classes are alive to their responsibilities and sensitive to the terrible risks both at home and abroad that misgovernment may involve.

It is exceedingly doubtful if the Monroe doctrine can be invoked continuously to protect misgovernment. South America is today the only large part of the habitable earth not owned or controlled directly or indirectly by one of the great powers, with the exception of China, and it is perhaps a question if China is not herself a great power. In Brazil there are about 1,500,000 Italians and 200,000 Germans, and the Japanese are beginning to come quietly in considerable numbers to the Southern states as well as all along the West Coast of South America.

Practically the whole continent, especially Brazil, possesses enormous undeveloped resources, lacking only the magic touch of capital, technical direction, and honest laws to foster and protect enterprises certain to yield returns equal to, if not surpassing, those in any other field of foreign investment.

As I have intimated, Brazil's contribution to the metallic wealth of the world is at present practically negligible. The causes have been variously explained, such as the comparatively recent liberation of the slaves in 1888. These people represented then, as now, the

¹¹*Trans. A. I. M. E.*, Vol. L (1914), p. 157.

bulk of the laboring classes and often when they don't want to work they won't, and it is very easy to say "won't" in a tropical or semi-tropical country where food may be grown with little effort and clothing is not a matter of fundamental importance. A more potent obstacle is the fact that Brazil is an agricultural country

WHARVES AT RIO DE JANEIRO.

Rio de Janeiro is equipped with an excellent system of modern docks, but they are not suitably arranged for handling ore in bulk. Consequently the manganese ore, upon arriving at the railway terminus, is transferred from the cars to lighters, by which it is taken to one of the small islands in the harbor, where it is stored in heaps until a shipment is to be made. In that event the ore is re-loaded into lighters that are then towed alongside the vessel, which is usually anchored out in the bay some distance from shore. The ore is thus necessarily handled four times from cars to vessel as against once in good practice wherein the car discharges its load by gravity directly into the hold of the ship.

whose people are conservative, unimaginative, and ignorant. All these causes have had their influence, but such reactionary tendencies could easily be overcome by some show of intelligent interest on the part of both

MORRO DA MINA, BRAZIL.

the Federal as well as the various State governments. Thus, for example, we have seen the able and self-sacrificing geologist Derby, who labored many years faithfully and unselfishly to study and make known the mineral resources of this enormous country, given a grudging

and half-hearted support that in the end appears to have broken his spirit, and probably had much to do in bringing about his tragic and untimely death.

This is not said in a spirit of unfriendly criticism; on the contrary, I wish simply to point out that any nation without a well-established mining and metallurgical industry is certain to be vulnerable in this day when munitions are as important as men. As I have tried to show, Brazil has an abundance—with the exception of coal—of raw material for the maintenance of a great metallurgical industry, yet I doubt if she produces any military munitions whatever. The logic of the situation would seem to be for the Brazilians to make every effort to expand and encourage their industrial development as rapidly as possible. Every inducement should be offered to American capital and enterprise; at present the United States is the only country prepared to provide it, and once an industry is fairly well started and is prospering, a policy of nagging interference, graft, and unfair taxation is likely to be fatal or bring about diplomatic interference, all of which is certain to discourage American investment in Brazilian enterprises.

Americans, as a rule, are unaccustomed and rather adverse to foreign investment; there are so many opportunities at home. Business abroad must be made very attractive in order to entice timid dollars into the uncertainties and worries of a foreign field. American capital may be plentiful, but it is well to remember that the whole world is now seeking it with an unprecedented zest, mainly to carry on a dreadful war; when that is over, Europe is likely to be all but bankrupt and must be rehabilitated. Moreover, Europe can get capital on easier terms than South America. The present is, it seems to me, the best opportunity Brazil has ever had to cultivate closer relations with the United States, and it might be well for both countries were this fact mutually realized.

EXPERIMENTS in the purification of crude sulphur containing arsenic have been continued at the Bureau of Mines experiment station at Berkeley. A centrifuge has been equipped with an electrically heated cup so that sulphur may be held molten and centrifuged for several hours at a time. In studying the solubility of arsenic tri-sulphide in molten sulphur it has been found that a solution containing 4% arsenic shows no indication of depositing a precipitate of arsenic sulphide after standing several weeks at 121° C. So far there has been nothing to indicate that a separation of arsenic sulphide occurs when its solution in sulphur freezes. This solubility work is being continued, and further experiments on fractional distillation of sulphur-arsenic mixtures are being arranged.

THE TERM, 'SLASH PINE,' is popularly applied to several southern pines, notably the loblolly, with which the true slash pine is often confused because of its close resemblance. The slash pine is also sometimes called Cuban, swamp, or 'she' pine.

Secondary Economic Minerals of California

By Herbert Lang

Aside from the precious metals, and the ores of lead, copper, mercury, and zinc, which have long been the object of the prospector's search, there are a large number of minerals of secondary importance in California to which it would be well for prospectors to give attention. That he may have some idea of the condition of the trade in these secondary minerals, the accompanying data have been prepared. The substances may be classified as follows:

1. **ABRASIVES:** Minerals used for grinding and polishing; as quartz, jasper, pumice, garnet, feldspar, and rotten-stone.

2. **DETERSIVES:** Minerals used for cleaning purposes, being incorporated in soap; as quartz, pumice, and infusorial earth.

3. **EMOLLIENTS:** Generally styled 'lubricants,' and used either by themselves or with some liquid, to lessen friction. These are mica, talc, clay, graphite, and soap-stone.

4. **ABSORBENTS:** The property of which is to take up liquids. These are fuller's earth, infusorial earth, and magnesite.

5. **FILLERS:** Used to adulterate or give weight to paper and other fabrics. Clay, talc, soapstone, and mica are the principal fillers.

6. **FERTILIZERS:** The phosphates and potassium-bearing minerals.

7. **NON-CONDUCTORS:** Substances that are poor conductors of heat. Any mineral in the form of powder does this, but infusorial earth, magnesite, and mica are pre-eminent.

8. **PAINT-STOCK:** Substances used to impart 'body,' color, or wearing quality to paint. These are barytes (sulphate of baryta), ochre, talc, manganese, silica, gypsum, and pumice.

9. **REAGENTS:** Substances valuable for their chemical properties, such as chrome, infusorial earth, quartz, limestone, and magnesite.

10. **REFRACTORIES:** Useful for their heat-resisting properties, such as chrome, clay, quartz, soapstone, and magnesite.

This classification might also include structural materials, the rocks and minerals used in cement manufacture, as well as those valuable for their decomposition products, obtained through chemical processes, but it is better not to include substances that are in an intermediate class between metallic ores on the one hand, and building-stone, road-metal, and soil on the other. This classification is found to embrace materials that are used solely in the powdered form, which is a distinguishing characteristic. The investigator is surprised at the amount and variety of mineral powders going into trade

and manufacture. It would seem that any stone, if finely or even coarsely powdered, may be saleable for some purpose. It is obvious, from this classification, that the simpler chemical composites are preferred, the value for the various purposes indicated being lessened as the substance becomes more complex. Thus, a powdered rock of high complexity, such as many of the silicates, would probably have no value except as soil; while each of its constituents separately would probably be of value for some purpose. There is a curious similarity in the price that different pulverized minerals bring—\$20 per ton, as a rough average. The following list exhibits the variations. The prices mentioned are those of pre-War times, because the present disturbed condition of the market precludes an exact statement of what the materials now bring in the local market.

Name	Price per short ton	Annual consumption, tons
Chrome	\$17.00	1,500
Barytes	20.00	1,000
Dolomite	11.00	3,000
Garnet	13.00	4,000
Gypsum	3.00	5,000
Infusorial earth (crude)	10.00	8,000
Infusorial earth (ground)	15.00	2,000
Mica (ground)	40.00	250
Ochre (ground)	17.00	1,000
Pumice	25.00	1,500
Talc (ground)	18.00	3,000
Quartz (crude)	2.50	10,000
Quartz (ground)	12.00	1,000
Manganese (ground)	25.00	250
Slate (ground)	22.00	500

These are San Francisco prices, and are a fair average of price and consumption before the War. In some particulars the trade has expanded, in others it has contracted; but on the whole the prices have increased greatly, and, owing to the introduction of improved processes and greater demand, the industries here represented are on an improved footing.

The principal trades and their requirements are represented in the following:

ACID MAKERS: Pyrite, nitre, brimstone, salt, fluorspar.

ASPHALT PAVING: Bituminous rock, gravel, limestone, infusorial earth.

AUTO TIRE-POWDER: Soapstone.

BRICK, TILE, AND TERRA-COTTA: Clay, talc, manganese, fluorspar, feldspar, ochre, willemite.

CEMENT MAKERS: Limestone, clay, slate, gypsum, ochre, fluorspar.

CEMENT SHINGLE MAKERS: Ochre, jasper.

CHLORINATION PLANTS: Salt, manganese.

CHEMICAL MANUFACTURERS: Salt, quartz, feldspar, fluorspar, manganese, chrome, infusorial earth, magnesite, dolomite, limestone, pyrite, baryta.

DRUG MANUFACTURERS: Pumice, talc, fuller's earth, silica.

DYNAMITE MANUFACTURERS: Infusorial earth.

DRY BATTERY MAKERS: Manganese.

ELECTRIC SUPPLY MAKERS: Mica, talc, asbestos, soapstone.

FIREBRICK MAKERS: Clay, chrome, silica, sand, magnesite.

FERTILIZER MAKERS: Limestone, gypsum, phosphate rock.

FLOUR MILLERS: Ground limestone.

GLASS MAKERS: Silica-sand, feldspar, fluorspar, manganese.

INSULATION (of boilers, etc.): Infusorial earth, asbestos, magnesite, talc, amphibole.

LITHOGRAPHERS: Lithographic stone, pumice.

LUBRICANT MAKERS: Mica, talc, steatite.

METAL-POLISH MAKERS: Silica, pumice, infusorial earth.

OIL REFINERS: Fuller's earth, silica.

PAPER MAKERS: Talc, clay, quartz, mica, magnesite.

PAINT AND VARNISH MAKERS: Talc, clay, ochre, manganese, limestone, silica, barytes, pumice.

PORCELAIN AND CHINA MAKERS: Feldspar, quartz, fluorspar.

PUTTY MAKERS: Ground limestone.

POULTRY-SUPPLY MAKERS: Limestone, sea-shells, crushed granite.

MAGNESIA-CEMENT FLOOR MAKERS: Magnesite, marble, dolomite, jasper, talc, silica, pumice, infusorial earth, ochre.

ROPE MAKERS: Talc, clay.

ROOFING MAKERS: Quartz, jasper, talc, infusorial earth, slate, mica, soapstone, clay, marble.

REFRIGERATOR AND FIRELESS-COOKER MANUFACTURERS: Infusorial earth, talc, asbestos.

RUBBER MANUFACTURERS: Steatite, talc.

RICE FACTORIES: Ground limestone, talc.

SCOURING-COMPOUND MAKERS: Pumice, silica.

SHOE MAKERS: Garnet.

SILICATE OF SODA MAKERS: Infusorial earth.

STONE FINISHERS: Pumice, rotten-stone, silica.

SOAP MAKERS: Talc, pumice, silica, soapstone, borax.

SYRUP MAKERS: Infusorial earth.

STEEL AND IRON MANUFACTURERS: Iron ore, chrome, manganese, talc, graphite, magnesite, dolomite, fluorspar, quartz, limestone.

SMELTERS OF COPPER AND LEAD: Chrome, quartz, manganese, fluorspar, limestone, dolomite.

SOUND PROOFING MAKERS: Infusorial earth.

SAND PAPER MAKERS: Flint, quartz, garnet.

SUGAR MANUFACTURERS: Infusorial earth, limestone.

STONE (artificial) MAKERS: White sand, quartz, marble-dust, limestone, granite, jasper.

TANNERS: Talc, chrome compounds.

WALL PAPER MAKERS: Mica, talc, magnesite.

WOOLEN MANUFACTURERS: Fuller's earth.

The commercial uses of the different minerals are recapitulated in the following:

ASBESTOS: In fire-proof paints, wall-plaster, patent shingles, roofing, incombustible curtains for theatres, cloth, rope, felted boards, asbestos-cement, paper-stock; in the fire-proof packing of safes and vaults; and in the non-conductive covering of boilers, steam-pipes and flues.

BARYTES: In the manufacture of paint, paper, rope, rubber; and of various chemicals, such as the carbonate, chloride, hydroxide of barium, and lithophone.

CHROME: In the manufacture of chrome-steel, used in making refractory brick, and in the construction of open-hearth and other furnaces used in steel manufacture. Its salts are used in tanning and in the manufacture of dyes and colors.

DOLOMITE: As a refractory lining for steel-furnaces, and as a flux in metal-smelting. Used also in the manufacture of whiting, and in the preparation of magnesian salts, in lieu of magnesite.

FLINT: As pebbles for tube-mills, used in ore reduction.

FELDSPAR: Used in the manufacture of cement, pottery, brick, tile, and enameled ware, porcelain, glass, artificial stone, chicken grits, in some soap, and as an abrasive.

FLUORSPAR: In cement, glass, porcelain, enamels, and sanitary ware; in steel and iron production as a flux; in the production of aluminum, and in the manufacture of hydrofluoric acid.

FULLER'S EARTH: Used in fulling wool, and largely in soap and oil-refining, as a bleaching, filtering, clarifying, and deodorizing agent.

GARNET: For abrasive purposes, and in the making of garnet-paper, a variety of sand-paper.

GRANITE (crushed): In the manufacture of flooring and artificial stone, and in exterior plastering.

GRAPHITE: In electrical appliances, stove-polish, paint, lead-pencils, lubricants, gun-powder, crucibles, in electrotyping, and glazing, and in dusting foundry-molds, and as a filler for dry batteries.

GYPSUM: In the manufacture of cements, plaster, paper, and glass, and extensively as a fertilizer.

INFUSORIAL EARTH: As an absorbent for nitro-glycerine in the manufacture of dynamite; as a non-conductor of heat, electricity, and sound; and largely for packing boilers and steam-pipes; as a fire-proofing material; in the manufacture of refractory brick; in polishing-powders, scouring-soap; for filtration, heat insulation, and refrigeration, and in making sodium silicate.

JASPER: Used as an abrasive, and in the manufacture of cement and concrete, artificial stone, flooring, roofing, and plasters.

KAOLIN (white clay): Used in the manufacture of paint, paper, pottery, porcelain, and soap.

LIMESTONE: Used by paper and sugar-factories, tanneries, smelters, makers of cement, fertilizers, and chemicals, and as an indispensable flux in iron, copper, and lead smelting.

MAGNESITE: In the manufacture of refractory materials, especially of brick for furnace and converter-linings; as an absorbent in dynamite making, as a non-conductor of heat; in the manufacture of paints; as hearths and as flux for furnaces. From the crude magnesite are obtained carbon di-oxide and magnesium sulphate, both useful materials, while the chloride is utilized in the preparation of magnesian or sorel cement.

MANGANESE: In the making of dry batteries, glass, paints, pottery, tile, and brick. Its alloys and compounds are employed in the manufacture of steel.

MICA: In the manufacture of lubricating oil and grease, and in making roofing, wall-paper, rubber, artificial stone, and insulating material.

OCHRE: In the preparation of paints of many colors and shades; in the manufacture of clay wares.

PUMICE: In paints, soap, metal-polish, and scouring-compounds; for structural purposes, sound and fire-proofing; in concrete blocks; and in the lump form, for polishing wood.

QUARTZ: In the manufacture of glass, paint, pottery, scouring, and other soaps, metal-polish, sand-paper, polishing-powder, artificial stone, plastering, and prepared roofing, and as a flux by smelters; as material for the sand-blast; for wood-filler, for filtering, for acid-towers, for the lining of smelting and other furnaces and by foundries. Also extensively used by chemical manufacturers, and in the making of ferro-silicon and laboratory ware.

ROTTEN STONE: As an abrasive.

SLATE: In the manufacture of paint, prepared roofing-paper, and artificial stone, and for insulating.

SOAPSTONE (steatite): In making laundry-tubs, bath-tubs, acid-tanks, fire-backs for stoves, hearth-stones, mantles, sinks, gas-tips, switch-boards, slate-pencils, and in artificial flooring.

TALC: In the paper, paint, and soap trades, chiefly as a filler; in the manufacture of roofing-paper, lubricants, toilet-powders, rubber, and crayons; in sizing, and in bleaching cloth; for the insulating of boilers and pipes, and as a foundry-facing.

Non-Corrosive Iron-Cobalt Alloys

An interesting publication of the Mines Branch of the Canadian Department of Mines deals with experiments conducted by Herbert T. Kalmus and K. B. Blake at Queens University. The experiments were undertaken to determine the effect of the addition of small quantities of cobalt on the atmospheric corrosion of iron and mild steel, particularly of the very pure product from the open-hearth process. The electrolytic theory of corrosion is generally accepted by engineers, yet it has been disappointing also, because of its failure to predict serious corrosion-phenomena, or to offer a remedy. It is common knowledge that two metals when alloyed often present greater resistance to corrosion than either component metal alone. This may be due

to the formation of a compound of the two metals, or under special conditions it may be due to the combination of one alloying metal with the impurities of the other, bringing the solution-tension of the resulting compounds into equilibrium. Alloying a second metal with iron or steel may also effect the corrosion of the original iron or steel by increasing or decreasing the amount of occluded hydrogen. Another important effect of introducing a second metal may be to form an oxide by corrosion, so adherent as to form a coating inhibiting further corrosion. The conclusions reached by Messrs. Kalmus and Blake are: that loss of weight through corrosion is a function of time, being less for the longer exposures. The addition of from 0.25 to 3% of copper, nickel, or cobalt to ingot iron (in these cases a sheet-roofing material supplied by the American Rolling Mill Co., of Middletown, Ohio, greatly increases the resistance to corrosion. In general the corrosion of the alloys formed by the addition of 3% of cobalt to American ingot iron is about three fourths as great as that of alloys formed by the addition of only 0.5% cobalt.

As corrosion progresses, all the alloys prepared form self-protective coatings of oxide-films. It is noticeable that in all cases the oxides formed on the alloy with cobalt are darker, denser, and more tenacious than those produced with alloys of copper or nickel. This does not, however, mean that the protective coating with cobalt will in the end prove most durable. Tests are being conducted to determine exactly the comparative values of cobalt, copper, and nickel, by corroding to destruction.

The amount of corrosion varies with the percentage of carbon in the alloy. It appears that moderately high carbon favors resistance, and that carbon remaining constant the resistance of the cobalt alloy surpasses that of the nickel or copper alloys.

Charges of mild steel were made up in a four-ton experimental furnace, so that the alloys thus produced could be rolled into full-size roofing-sheets for subjection to corrosion-tests. The sheets are 30 by 96 in., No. 26 gauge (0.0188 in. thick).

ANALYSES

	Ingot iron	Ingot iron with 1% cobalt	Ingot iron with 0.6% cobalt	Ingot iron with 1% Monel metal
Sulphur	0.026	0.034	0.040	0.025
Phosphorus .	0.009	0.006	0.008	0.008
Carbon	0.010	0.015	0.010	0.010
Manganese .	0.022	0.017	0.020	0.015
Copper	0.016	0.028	0.024	0.24
Cobalt	1.18	0.60	...
Nickel	0.75

These sheets have been corroding since March 1914, and it will take another year for any of them to corrode through to destruction. The loss of weight by the sheets containing cobalt is materially less than by the others. Both the cobalt sheets have formed hard dense protective coatings. The greatest corrosion is shown by the sheet containing neither cobalt nor nickel. Copper has also proved extremely efficient as an alloy-metal for retarding corrosion of the iron.

The Sulphide-Filming Plant at Magma, Arizona

By J. M. Callow

*The process in use in this plant is covered by the Schwarz U. S. patent No. 807,501, which is the first disclosure of the use of a soluble sulphide for converting an oxide of a metal into a superficial sulphide, and afterward recovering it by a flotation process.

Our earliest experiments were made with H_2S gas as the filming agent. A plant of 25 tons daily capacity was built. In this the gas was applied to the pulp by introducing it into the bottom of an open tank, having a mixing-agitator. The results were encouraging, but the consumption of gas was prohibitive—as much as 8 or 10 lb. per ton. The ore treated was the tailing of the Magma sulphide mill, which at that time carried considerable oxides. Occasional recoveries of 60% (of the total copper) were made, but the results were erratic owing to the difficulty of getting uniform filming of the pulp. Then followed an interval of several months when we used sodium sulphide, calcium sulphide, and calcium sulph-hydrate, in an endeavor to avoid the use of gas, on the assumption that it was objectionable owing to the danger of its poisoning the surrounding atmosphere. This was true when attempting to use it in an open tank. During this time a number of theories were advanced and abandoned. One of these was that natural and artificial sulphides could not be floated together, and that H_2S interfered with the flotation of the natural sulphides. Our experience now is that H_2S , in the proper quantity, really promotes flotation of natural sulphides in company with the filmed oxides, and also that it is immaterial whether the oiling is done before or after filming. Whichever plan is followed is merely a matter of convenience.

In treating sulphide tailing, in which the principal losses were sulphides, the introduction of the gas not only filmed the oxides present, a goodly percentage of which was recovered, but it also raised an entirely new crop of refractory sulphides. An all-sulphide sample of regular Magma ore was tested with and without H_2S . The results are given in Table 1.

The mill-plant was shut-down and we again reverted to laboratory work, which resulted in our adherence to H_2S in preference to any other agent on this particular

ore, and also to a complete change in our method of applying it. The plant was re-constructed, crushing machinery and additional cells being added in accordance with the flow-sheet shown in Fig. 1, for the purpose of treating Magma oxidized ores on a commercial scale.

The gasing method used at present introduces the gas

FIG. 1.

into the suction of a centrifugal pump in the manner indicated in the flow-sheet. This has proved effective, greatly reducing the consumption of gas, giving more uniform recoveries, and has removed all danger from the poisoning of the atmosphere; in fact, the commercial results now being obtained date from the first use of this expedient.

The present method of making H_2S gas is to heat sulphur and oil in a retort. Various proportions of sulphur and oil have been tried, our present proportions being 1 of sulphur to $2\frac{1}{2}$ of oil. The temperature in the retort is kept uniformly at $300^\circ C$. At times the making of gas has given trouble, owing to changes in the quality of the oil used. Satisfactory results have been obtained at all times with Californian crude oil, but Texan oil al-

*Excerpt from 'Notes on Flotation—1916,' a paper read at the New York meeting (Feb. 1917) of the American Institute of Mining Engineers.

C.T. = coal tar. C.T.C. = coal-tar creosote. F.O. = fuel oil. P.T.O. = pine tar oil. C.P.O. = crude pine oil.

ways gives trouble, making a gas containing what we believe to be hydrogen persulphide, which interferes with flotation, and can always be identified by its eye-burning properties. This is in a measure overcome by careful scrubbing, sulphur being precipitated in the scrubbers with free H₂S liberated.

TABLE 1. EFFECT OF H₂S ON NATURAL SULPHIDES
MAGMA SULPHIDE ORE

No H ₂ S gas	Heading	Tailing	Concentrate	Recovery
Test 1	2.45	0.22	11.82	92.70
Test 2	2.45	0.25	9.62	92.20
Average	2.45	0.235	10.72	92.45
With H ₂ S gas in excess				
Test 1	2.45	0.28	9.40	91.30
Test 2	2.45	0.20	8.41	94.10
Average	2.45	0.24	8.90	92.70

The Californian crude oil has the following fractional analysis:

Specific gravity, 0.9311 or 20.36 B. at 15° C.

Flash point (open dish), 108° C.

Fractionation:

Temperatures, °C.	Distillate, cc.
100-150	1.2
150-175	1.6
175-200	3.6
200-225	9.6
225-250	22.0
250-275	30.8
275-300	25.2

Free gas in a pulp is fatal to flotation, hence the use of the blowing-cell at the head of the first flotation-cell.

TABLE 4

Date	Test No.	Tonnage Rate	Heads	Tails	Concentrates	Ratio	Recovery

				-150 = 86.4 per cent.				

NOTE.—No tables were used in this flow sheet. The results would have been improved if there had been.

Experiments indicate that heating the pulp slightly before gasing is beneficial.

The cost of manufacturing the gas by this method will, of course, vary greatly according to local conditions. Those at Magma are abnormal. Sulphur is costing nearly 3c. today, and oil nearly 1c. per pound, f.o.b. Superior, and costs on a basis of 30 tons per day, and maximum of 3 lb. per ton, stand as follows: 90 lb. of sulphur at 2.74c., \$2.51; 225 lb. of oil at 0.914c., \$2.16; total, \$4.77 = 15.25c. per ton, or approximately 5c. per ton for each pound of sulphur per ton required by the ore.

On Magma sulphide tailing, the consumption of gas varies from $\frac{1}{2}$ to $1\frac{1}{2}$ lb. sulphur per ton. On strictly carbonate ore, assaying 3 or 4% copper, 3 lb. is an average figure, and on the latest test with a mixed carbonate and silicate ore, assaying from 4 to 5% copper, 2 lb. of sulphur per ton. The fuel required for heating the retort is almost negligible. There are no figures for cost since so far we have been burning scrap-lumber left over from construction. The labor item is unduly heavy because the retort is situated some 600 ft. away, and one man has to be held in reserve for the purpose. He could as easily make gas on one shift for 500 tons per day. With sulphur and oil at moderate prices on a 500-ton scale, using 2 lb. of sulphur per ton, my estimate of the total gas-cost is as follows:

1000 lb. sulphur at \$45 per ton = 2.25c. per lb.....	\$22.50
2500 lb. oil at \$1.75 per barrel = 0.436c. per lb.....	11.00
1 man at \$4.....	4.00
Extra fuel for heating retort and sundry repairs.....	2.50

Per day\$40.00

Thus the probable cost is 8c. per ton of ore, or 4c. per ton for each pound of sulphur required for the ore.

Other methods were tried—one using powdered coal in a separate retort instead of the oil-mixture, and an-

other in which the oil instead of being mixed with the sulphur was dripped into the sulphur-retort with a force-feed lubricator. The usual iron matte and sulphuric acid method was also tried but none of these methods had anything to recommend them. Iron matte was never seriously considered on account of the recent high price of acid.

The flow-sheet given in Fig. 1 is self-explanatory: The 6-ft. by 18-in. Hardinge ball-mill has a capacity of 35 tons per day when loaded with balls requiring 35 hp., or 45 tons per day when loaded up to 50 hp. requirements and grinding 83% through 150 mesh.

The power requirements are distributed as follows:

1 6 ft. by 16-in. Hardinge ball-mill.....	35 hp.
1 8-ft. by 14½ Root blower, No. 1 (400 cu. ft. at 5 lb.).....	20 hp.
1 7 by 14 Dodge crusher (1 shift only).....	
1 2-in. centrifugal gasing pump.....	
1 4-ft. diaphragm pump.....	
1 10-in. belt-drag classifier.....	
1 Oil-feeder.....	
1 Ore-feeder.....	55 hp.

This is the equivalent of 37.6 hp.-hr. per ton = 28 kw.-hr. per ton.

The plant is operated by four men for the three shifts, the extra man on day-shift crushing the ore and hand-sorting any first-class ore.

Table 2 gives the results of gasing the sulphide mill-tailing, the feed in all these experiments being that given to the lower or 'gleaner' cells, as they are described on the flow-sheet. The soluble copper in these tests varied from 0.3 to 0.45% and the average for the entire period was 0.35%. Attention is directed to tests No. 63A and 67, showing results on this feed without gasing; further comparisons of more direct kind are given in Table 3.

The results on strictly carbonate ore are given in Table 4, and on a mixed carbonate-silicate-sulphide ore in

TABLE 3. EFFECT OF H₂S ON MINED SULPHIDES AND OXIDES
IN MAGMA SULPHIDE TAILING

No H ₂ S	Heading	Tailing	Concentrate	Recovery
Test 1	0.86	0.67	9.86	23.70
Test 2	0.78	0.60	9.63	24.70
Average	0.82	0.635	9.74	24.20
With H ₂ S				
Test 1	0.81	0.30	5.05	67.11
Test 2	0.78	0.29	5.51	66.38
Average	0.79	0.295	5.28	66.24

Table 5. The latter tabulation gives a complete record, and shows the contribution that hand-sorting makes to the total recovery. The carbonate results, for the most part, were on the rejections from the hand-sorting done at the mine, but in all these results the headings, referred to, are actual mill-feeds, and the effect of hand-sorting is, therefore, not shown. On the mixed ore, gravity-tables on the flotation-tailing would have added considerably to the total recovery, but on the straight carbonate ores they would have served no purpose.

While on carbonate ores the results may be considered very satisfactory, there is still considerable work to be done on the mixed ores. Several points are still obscure, which will take time, further experimenting and research to overcome. These are: (a) Uniform quality of gas, and what are the interfering elements in poor gas? (b) Why are silicates and the coarser sizes of carbonate mineral more difficult to film than fine carbonates?

The present results are encouraging, and positive enough to lead us to believe that in due time all such ores as these will be as successfully treated by this process. As to the treatment of oxidized ores other than copper, so far we have not been able to film zinc carbonates at all but lead carbonates are comparatively easy. We have had no success with gas on these, but sodium sulphide gives excellent results. The following figures are the average of 13 different experimental runs made, treating a lead-carbonate tailing-dump at the Prince Consolidated, Pioche, Nevada: heading, 6.97%; tailing, 1.85%; concentrate, 38.81%; ratio, 7.21:1; recovery, 77.28%.

Graphite at Llano, Texas

*The older schists and gneisses of Burnet and Llano counties, Texas, contain promising deposits of flake graphite. Two mills have been built and put in operation, that of the Texas Graphite Co., nine miles west of Burnet, and the Heath, five miles north-east of Llano. The Heath was operated as a gold mine for a short time, but Llano County gold mines have not been remarkable for profits obtained.

Many years ago I made reports on the graphite deposits in Clay county, Alabama. Later, Ernst Prochaska built and operated a mill for Paul Gilardoni, of

Birmingham, and produced an excellent quality of flake graphite. It is an interesting contribution to present-day flotation methods to know that Mr. Prochaska "floated" his concentrates with lubricating oil. This was 23 years ago, or about the time that Carrie Everson was "floating" ore concentrates with oil in Colorado. Mr. Prochaska was probably the first in this country to use flotation methods in concentrating graphite. He used an ordinary lubricating oil.

The graphite deposits in Burnet and Llano counties are remarkable for the excellent character of the flake graphite held in the schist. There is but little black mica present, so that this bane of the graphite miner is not a factor in concentration. The gangue is highly silicious, with soda feldspar as the chief additional constituent. The content of the schists in flake graphite varies from 8 to 10% mill run, with occasional masses of much higher content. The extent of the deposits is certainly large, far beyond any possibility of exhaustion for many years. Much of the mining is mere quarry work, three miners supplying the mill with 25 tons of crude material per day of 24 hours. The following estimate gives a close approximation to the cost of operating a 25-ton mill per day of 24 hours:

Superintendent	\$4.93
Chemist and bookkeeper	2.96
Two drivers	5.26
Ten mill-men	25.00
Two trammers	4.00
Two hoist-men	5.00
Two carpenters	7.00
Eight muckers	16.00
Three miners	7.50
One pump-man	2.00
One blacksmith	3.00
One electrician	3.50
One pipe-line man.....	2.50
	<hr/> \$88.65
75 gallons of oil at 3 cents, for the oil engine.....	2.25
4 gallons of lubricating oil at 32 cents.....	1.28
2 cords of wood for one of the boilers.....	3.00
	<hr/> \$95.18

Allow \$4.82 additional for unforeseen emergencies, and the total daily cost will be \$100, or \$4 per ton of crude material. The \$4.82 additional will take care of power, repairs, wear and tear, water, etc. This plant was making a concentrate containing not less than 50% of graphite carbon, as flake graphite, and was meeting a contract obligation for graphite of that quality. It produced 350 pounds of this concentrate from a ton of crude material selling for 3 cents per pound f.o.b. railroad cars. The value of the concentrate from a ton of crude material was therefore \$10.50; the cost of mining and treatment, as per the above items, was \$4. Laboratory experiments on a considerable scale have shown that this concentrate can be re-ground and re-concentrated and the content of flake graphite brought up to 87%.

There is opportunity in Burnet and Llano counties for a considerable graphite industry. The product would be flake, or crystalline graphite, always easily marketed.

*Abstract from article by W. B. Phillips, *Manufacturers Record*.

The Miami Appeal—II

In our issue of February 3 we reproduced part of the defendant's brief before the U. S. Circuit Court of Appeals at Philadelphia. Herewith we give two extracts from plaintiff's oral argument, as made by Mr. W. Houston Kenyon. We quote verbatim.

Mr. Scott classifies these surface-tension processes off by themselves. He has a heading, "Surface tension flotation."

"Surface tension flotation is also known as film flotation or skin flotation. This form of flotation has never been widely adopted, but some understanding of it is necessary in connection with a comprehensive explanation of the subject of flotation generally."

It is what we describe as the greased needle effect, and at the bottom:

"In surface tension or skin flotation the floating layer is substantially only one particle thick."

That is all you can get, just one particle thick. The amount of matter that can be floated by surface tension is so minute. Here Mr. Scott says it is a characteristic of this process, that the floating layer is only one particle thick, and the amount of matter that can be floated in that way is so minute as to render any flotation process based on this phenomenon of little or no value, owing to the immense water surfaces that would be necessary in order to float any considerable amount of mineral.

Then he quotes evidence to that effect. There can be no sort of question that that is a fact as to the mode of procedure, the mode of working out of that bubbles machine, and there can be no possible sort of question but that that was the purpose and intention of the bubbles patentees in the matter of those machines of Fig. 1, 2, and 3.

THE COURT (Buffington, C. J.): What do you conclude from all of that?

MR. KENYON: That that process does not justify the defendant's process, which defendant's process is not a skin flotation process, but like ours—a froth.

THE COURT (Buffington, C. J.): In other words, that it does not anticipate the patent?

MR. KENYON: And it does not justify the defendant—

THE COURT (Buffington, C. J.): Of course it does not justify them if it does not anticipate the patent.

MR. KENYON: It does not take the defendant outside of the construction and scope of the patent. It has no effect at all to limit the scope of the patent in suit, first, because the amount of oil, the critical amount of oil which we disclose, and which is the kernel of our step in advance, and which the defendant employs, is not disclosed and secondly because it is not a froth flotation process at all.

THE COURT (Buffington, C. J.): It shows the method

by which they use air in this treatment, and how they use it in their treatment.

MR. KENYON: Yes. It shows an attempt to utilize the buoyancy of air bubbles in the concentration of ore, and it failed, the evidence is complete to that effect in the record, and why did it fail? It failed because its fundamental conception was that the use of air should be limited to a skin flotation process. The air bubbles merely bring the metal particles to the surface and have no further function—drop them there. And secondly, it fails in that it discloses no conception that by using this minimum amount of oil, this one-tenth of one per cent, you would get a bubble which would not let go of the metal particle and burst when it got to the surface, but you would get a bubble so persistent that it would hang onto the metal particle and other bubbles coming up would hang onto other metal particles and so they would build up a froth which would lift the metal particles above the surface of the water, carry them in what the patent calls a froth, an accumulation of bubbles, and in any way deliver them over the lip or the dam for the purpose of ore concentration.

Now the patentees of the first patent in suit took that step in arriving at their process; they conceived, or let us say, walked with their eyes shut upon (because I believe that was the literal fact)—walked with their eyes shut upon—the phenomena that with the ore pulp and the agitation which they were using to send the metal down, but with that minute proportion of oil, instead of going down it came up in a copious froth and carried the metal with it up to the surface, and through and out of and above the surface and into a froth that was fitted to become the carrier and conveyor of that value so that it could be separated out.

THE COURT (Buffington, C. J.): The froth obtained in a particular way?

MR. KENYON: A particular way.

THE COURT (Buffington, C. J.): By beating in the air?

MR. KENYON: No, not by beating in the air.

THE COURT (Buffington, C. J.): Then how is this froth obtained or introduced? By beating in the air?

MR. KENYON: It is obtained by the presence in the ore pulp of that kind of a bubble which is produced by modified ore pulp, ore pulp with this minute quantity of oil in it, and the collision—

THE COURT (Buffington, C. J.): What is bothering me is—do you get the same kind of froth these defendants do?

MR. KENYON: Absolutely.

THE COURT (Buffington, C. J.): Why is it, then, that their froth subsides and yours does not?

MR. KENYON: That is simply a question of degree—that is simply because they have super-saturated it with

air. Theirs, you can see, is a thinner froth than ours. More air, less metal.

THE COURT (Buffington, C. J.): You mean they have got more agitation?

MR. KENYON: No, I should say we—

THE COURT (Buffington, C. J.): How do they supercharge it with air?

MR. KENYON: By blowing in endless quantities of air at the bottom.

THE COURT (Buffington, C. J.): Then they are blowing in that air by compressed air more violent than your method of agitation. Is that it?

MR. KENYON: I should not say that. I should say they introduced more air in there. I should say it was perhaps one hundred times—I don't know—

THE COURT (Buffington, C. J.): If it gets more air, and it can be done instantaneously, why, then, do you have to do it from two and a half to ten minutes?

MR. KENYON: I think we have to do it from two and a half to ten minutes simply because the Gabbett cone is such an inefficient way of getting air in, your Honor.

THE COURT (Buffington, C. J.): In other words, this method of introducing air from below is better than your method?

MR. KENYON: That is, in and of itself, as a method of introducing air, for the purposes of our process, it is an improvement.

THE COURT (Buffington, C. J.): Now, if they have a better method of the introducing of air, what have you to say about the construction of these claims, when you withdrew the first claim, and were precluded from getting all the claims. That is what I want to get down to.

MR. KENYON: Let me go right to that. What was that claim? It was for the use of these critical proportions of oil—this critical proportion of oil—in an ore pulp, and thereby effecting concentration, whether by skin flotation, or whether by froth procedure, or whether by sinking. There was no limitation in that claim to froth or to any way of getting froth, but simply to the bald, broad combination in any process of an ore pulp and that minute proportion of oil, and the result, ore concentration.

Now, what did they reject that on?

THE COURT (Buffington, C. J.): I do not care what they rejected it on.

MR. KENYON: It is important.

THE COURT (Buffington, C. J.): What did the claim mean? No matter whether they, in rejecting it, did make a mistake. It was abandoned by the patentees.

MR. KENYON: Yes. That is, we abandoned any claim to this minute proportion of oil in an ore pulp *per se*, regardless of what it did and we limited ourselves to the combination of that critical proportion of oil in an ore pulp and agitation and a froth. Those are the only two things that were added, and the froth as the result of such agitation as brings the air particles and the oiled metal particles in contact, whereupon they rise by the laws of nature. An accumulation—

THE COURT (Buffington, C. J.): Then, you come down

to those two elements. Now, the Supreme Court has said that you got that agitation by a method which they found very original?

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): And you get a certain kind of froth?

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): Then, you have got here to meet another method of agitation, to wit, by air from down below.

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): You have got to meet a different kind of froth?

MR. KENYON: Let us say agitation by aeration.

THE COURT (Buffington, C. J.): By what?

MR. KENYON: By aeration. Agitation by aeration. That is by introducing air—by aeration.

THE COURT (Buffington, C. J.): You have got it by the compressed air coming in?

MR. KENYON: Yes.

THE COURT (Buffington, C. J.): Is that within the terms of your claim as the Supreme Court has construed the patent?

MR. KENYON: I believe it is, although the Supreme Court had no such question before it. My whole argument is just going to lead right along that line, and I have a great many facts to present to you that bear this way and that way on that. But the defendant has departed from this process of the prior art (by which it justifies), by the utilization of air, of a bubble, of a different character, the sort of air bubble that forms in a modified pulp, and the evidence is clear that that sort of air bubble is different in character, so different that when it gets out of the water it persists. There is the secret of this froth process. And the defendant utilizes these peculiar bubbles as a *froth-forming instrumentality*, which carried the metal particles up *through* the water surface and, by reason of the persistency and coherency imparted by the oil in the critical proportions, sustains them there above the water surface in and as a metal-bearing froth and so separates the metal from the gangue. The defendant takes from this bubbles patent only the way in which it introduces the air, namely, from the bottom.

Now, I shall in a moment present the complete equivalency of those two ways of introducing air, but first let me show that what the defendant has done satisfies the claims of the patent in suit, so far as words go, for no particular kind of agitation is recited in these claims, and no particular kind of froth, simply agitation, simply froth, and we do not have to argue about the fact that both those things exist there, however produced; and it satisfies the specifications—it satisfies the specifications, where two examples are shown, and the last one never called to the Supreme Court's attention, because they were not construing the patent. The first patent in suit illustrates the invention by two examples, the first the revolving cone mixer with baffles, and the second, the agitation of rising bubbles on relief of pressure.

Socketing Wire-Rope

Miners are sometimes at a loss to find what they consider a good way to secure the end of a hoisting-rope in the socket to which the hook is to be attached. In one of the wire-rope catalogues of the John A. Roebling's Sons Company is illustrated and described a method of doing this that has been found to give satisfactory results. It is here reproduced:

DIRECTIONS FOR SOCKETING A HOISTING-ROPE. (Follow the illustrations).

1. Measure from end of rope a length equal to basket

PROPER METHOD FOR SOCKETING A HOISTING-ROPE.

of socket. Serve at this point with not less than three wraps. Cut out hemp centre—open strands.

2. Separate wires in strands, straighten by means of iron pipe, cleanse with kerosene oil, wipe dry.

3. Dip wires into one-half muriatic acid, one-half water (use no stronger solution). Keep wires in long enough to be thoroughly cleansed—wipe dry. Serve end that socket may slip over all of wires.

4. After placing on socket, cut serving wire at top—have all wires evenly distributed and even with top of basket—place fire-clay around bottom of socket.

5. Pour in molten pure zinc—do not use babbitt.

6. Remove all servings except one nearest socket. After cooling it is ready for service.

Mining in Utah
